Methods.—We used the method of Coulson et al. (1944) and Ellinger et al. (1945). For three days 24-hour urines were collected with the patients on ordinary hospital diet. For the next five days the same procedure was continued except that the patients were given 100 mg. of nicotinamide at the beginning of each 24-hour period. Each test therefore lasted eight days. To 2 controls, 2 cases of sprue, 6 of convalescent sprue, and 4 of amœbiasis the nicotinamide was given parenterally. To the remainder—7 controls, 4 cases of convalescent sprue, and 3 of amœbiasis—the vitamin was administered by

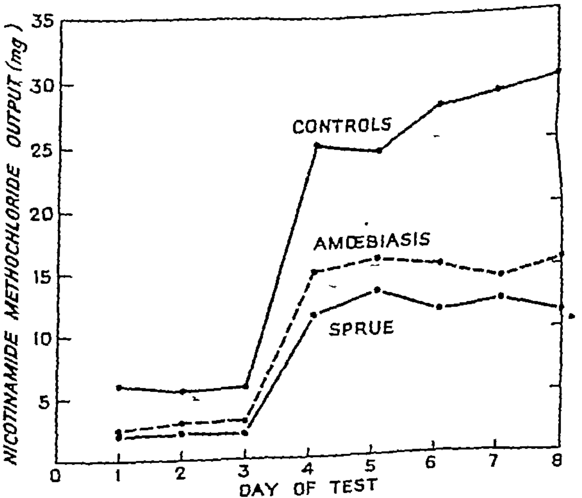

Fig 1—Average output of nicotinamide methochloride in sprue amœbiasis, and controls.

mouth. All cases of florid sprue (2) and amœbiasis (2) with looseness of the bowels received the nicotinamide parenterally to exclude the possibility of poor gut absorption.

Briefly, the method of determining the amount of nicotinamide methochloride in the urine (Coulson et al. 1944, Ellinger et al. 1945) is as follows:

> Nicotinamide methochloride is separated from urine by adsorption on 'Decalso,' from which, after washing with distilled water, it is eluted by potassium-chloride solution, then rendered alkaline, and extracted with iso-butyl alcohol. The fluorescent derivatives thus produced are compared by visual fluorimetry with standards similarly treated.

Results.—The results in controls, sprue, and amœbiasis, given in the accompanying figures (1–4), may be briefly summarised as follows:

(1) The controls produced figures of the same order as those of Ellinger et al. (1945).

(2) There was a subnormal excretion, resting and after test dosing, in patients convalescent from sprue who had had no symptoms for three months or more and had had nicotinic acid, 'Vegmite,' and liver treatment in India. Figures of excretion in this group were slightly higher than those of Ellinger et al. (1945) for pellagra.

(3) The excretion in two cases of florid sprue investigated did not differ from that in the patients convalescent from sprue.

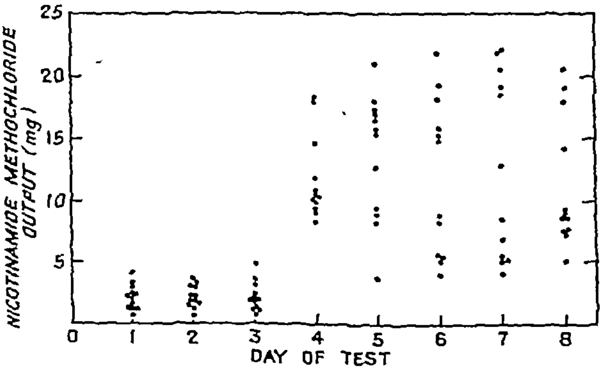

Fig. 2—Scatter diagram of nicotinamide methochloride output and saturation tests in sprue.

(4) Whether nicotinamide was given orally or parenterally to patients convalescent from sprue and to controls, the level of excretion was similar. This indicated that poor intestinal absorption of the vitamin was not a factor in cases without intestinal "hurry."

(5) Patients with amœbiasis, either with active disease or cyst passers, showed less excretion than the controls, and a slightly higher excretion than the sprue cases. Only two of these cases had diarrhœa, and both received their nicotinamide parenterally.

Comments.—The subnormal excretion in patients convalescent from sprue, who had no symptoms and had had their fill of nicotinic acid during treatment, was surprising. Not less surprising was a similar deficient excretion in cases of amœbiasis, mostly inactive from the point of view of intestinal "hurry."

It is impossible to draw any conclusions from these few results, and a larger series is required to confirm them. If, however, deficient nicotinamide-methochloride excretion in these cases can be shown to be due to subnormal intestinal biosynthesis and not to other factors (Perlzweig et al. 1943, Ellinger and Coulson 1944), our observations may be significant. We suggest tentatively that, behind this deficient nicotinamide-methochloride excretion in sprue and amœbiasis there may lie deficiencies of other

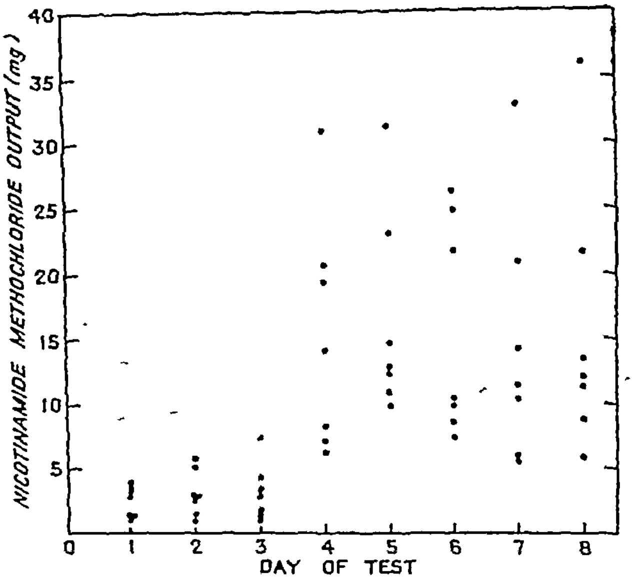

Fig. 3—Scatter diagram of nicotinamide methochloride output and saturation tests in amœbiasis.

members of the vitamin-B complex, known or unknown, whose relation to sprue may be of direct importance.

We have been obliged to leave this investigation in an incomplete state, and neither of us is likely for some time to be in a position to continue it. We feel, therefore, that these rather unexpected results should be recorded in the hope that they may be confirmed or otherwise, and possibly be of use to others continuing research in this field.

We agree with Leishman (1945) that the success of further research into this subject will depend on coördinated endeavour, an adequacy of clinical material, and laboratory facilities capable of coping with complicated and tedious analyses and assays.

We should like to thank Squadron-Leaders A. F. N. Noven, K. N. Lloyd, and J. D. Whiteside for sending us suitable cases, and Roche Products Limited for supplies of nicotinamide.

RELATIONS OF STEROID HORMONES AND ANHYDRO-HYDROXY-PROGESTERONE TO FIBROMATOSIS

RIGOBERTO IGLESIAS, M.D.

ALEXANDER LIPSCHUTZ, M.D.

DIRECTOR OF THE DEPARTMENT OF EXPERIMENTAL MEDICINE,
NATIONAL HEALTH SERVICE, SANTIAGO DE CHILE;
PROFESSOR IN THE UNIVERSITY OF CHILE

UTERINE and other abdominal fibroids induced by œstrogens in the guineapig (Iglesias 1938, Lipschutz and Iglesias 1938, Lipschutz and Vargas 1939, Lipschutz et al. 1940) can be prevented by different steroids absorbed simultaneously with the œstrogen (Lipschutz et al. 1939, Lipschutz and Vargas, 1941a and b, Lipschutz et al. 1941, Lipschutz and Zañartu 1942, Iglesias et al. 1944), and fibroids already induced regress when an antifibromatogenic steroid is given (Lipschutz and Maas 1944, Lipschutz and Schwarz 1944).

A systematic search for antifibromatogenic steroids has shown that all the steroids capable of preventing œstrogen-induced fibroids—progesterone, desoxycorticosterone, dehydrocorticosterone, testosterone, and dihydrotestosterone—were 3-keto-steroids (Lipschutz 1944). Of these progesterone was the most active. Five other 3-keto-steroids were *not* antifibromatogenic in the quantities used: pregnanedione, allopregnanedione, Δ^{16}-dehydroprogesterone (Lipschutz et al. 1944), androstanedione, and cholestenone (Iglesias and Lipschutz 1944). On the other hand, no steroid with a hydroxyl group in position 3 was *antifibromatogenic*: androsterone, Δ^{5}-androstenediol, androstanediol (Iglesias unpublished), Δ^{5}-acetoxypregnenolone (Lipschutz et al. 1943), Δ^{5}-pregnenolone-3-acetate (Iglesias and Lipschutz, unpublished).

Our work on the antifibromatogenic activity of different steroids in relation to their chemical structure is of interest with reference also to the hormone treatment of other tumours, including cancer. Steroids have been shown to prevent many forms of œstrogen-induced atypical growth: the hyperplasia of the prostatic stroma and the metaplasia of the utriculus in macaous (Zuckerman 1936, Zuckerman and Parkes 1936, de Jongh et al. 1938), and the fibromyo-epithelioma of the prostatic region in the guineapig (Lipschutz et al. 1945). But steroids are active also against different *spontaneous* tumours in laboratory animals: the mammary adenocarcinoma of the mouse (Lacassagne 1937, Lacassagne and Raynaud 1939, Nathanson and Andervont 1939, Jones 1941, Loeser 1941, Heiman 1944, 1945), the mammary adenofibroma of the rat (Heiman 1943), a transplantable thoracic tumour in the mouse (Heilman and Kendall 1944), the leukæmia of the mouse (Murphy 1944, Gardner et al. 1944).

Steroids have been applied also in human pathology. Though success seems to be inconstant with testosterone treatment of mammary carcinoma, there may be sometimes good results (Fels 1944). Œstrogens also have been applied in similar cases (*Lancet* 1944). Fundamental progress has been achieved in the hormone treatment of prostatic cancer thanks to the work of Huggins (1943); see also Dodds (1944).

Hormones have been used also for the treatment of uterine fibroids in women (Loeser 1938, and many others). The work of Greenblatt (1943, 1944) with subcutaneously implanted testosterone-propionate pellets deserves special mention. Favourable results have been obtained also by workers associated with this department, (Vargas et al. 1945). Objections can be made against the use of testosterone because of its virilising action (Hamblen 1942), though this is only transitory (Palmer and De Ronde 1943), and because of its being active only on injection or on subcutaneous implantation of tablets and not when given by mouth.

PROGESTERONE AND ANHYDRO-HYDROXY-PROGESTERONE

Progesterone has in the guineapig a stronger antifibromatogenic action than has testosterone (Lipschutz 1942a and 1942b, 1944). But, like testosterone, progesterone is considerably less active when given by mouth than on injection; the progestational activity of progesterone given by mouth is, according to Miescher and Gasche (1943), only 1/160th of the activity of injected progesterone. Though, as shown by our previous work, progestational activity is not an absolute criterion of antifibromatogenic activity, the fact remains that progesterone which exerts the strongest progestational action also exerts the most antifibromatogenic one.

For the above-mentioned reasons an experimental study of the antifibromatogenic action of anhydro-hydroxy-progesterone (A.H.P.), or ethinyl-testosterone, has been undertaken in this laboratory. This synthetic compound is due to Ruzicka et al. (1938) and to German workers. Its biological properties have been studied by different authorities and have been described in an exhaustive study by Emmens and Parkes (1939). The androgenic activity of injected A.H.P. (in propylene glycol) was in the capon comb-growth test, according to Emmens and Parkes, only about 1/600th of the activity of injected testosterone, whereas the progestational activity of A.H.P. was in the rabbit test 1/10th of that of the injected progesterone. According to Miescher and Gasche (1943) A.H.P. (in sesame oil) has 1/5th of the activity of progesterone. But A.H.P. is equally active by mouth and by injection in producing progestational proliferation.

PREVENTION OF ŒSTROGEN-INDUCED UTERINE AND ABDOMINAL FIBROIDS IN THE GUINEAPIG BY ANHYDRO-HYDROXY-PROGESTERONE

Small tablets of α-œstradiol were implanted subcutaneously into forty-five castrated female guineapigs; 1–8 tablets of A.H.P. 5 mm. in diameter were also implanted, to obtain absorption of variable quantities of A.H.P. The quantity of α-œstradiol and of A.H.P. absorbed was calculated from the loss of weight of the dried tablet divided by the number of days. This gives only an approximate figure, as absorption per day diminishes with time (Folley 1943, Shimkin et al. 1944, Bishop and Folley 1944), and substances from outside the tablet are entering into it (Folley 1942, 1943). Absorption per day was about 0·4 µg. per sq. mm. of the tablet; this is about fifteen times less than with progesterone. Necropsies were done three months after

TABLE I—ANTIFIBROMATOGENIC ACTION OF ANHYDRO-HYDROXY-PROGESTERONE (A.H.P.) IN GUINEAPIGS

Group	α-œstradiol per day (µg)	Antifibromatogenic steroid per day (µg)	Average F.T.E. (units)*	No. of animals	Animals reaching 5·5 units†	Regional marks 2 and 3 per animal‡	F.T.E. range (units)
I	16–57	0	5·7	23	12	1·9	1–10
IIa	24–55	A.H.P. 14–25	7·1	7	5	2·6	1–11
IIb	14–64	32–85	5·3	9	6	2·0	2–8
IIc	21–84	100–191	2·5	23	3	0·5	0·5–7
IId	55–95	210–347	2·1	6	0	0·3	1–4
III	21–63	Progest. 13–24	1·4	14	0	0	1–2·5

Progest. = progesterone.

* Fibroids of four regions (uterine-subserous and parametric; of the abdominal wall; the mesosalpinx; of the mesentery and of the spleen) are classified separately and marked 0·5–1–2–3, according to size. The fibrous tumoral effect (F.T.E.) is the sum of the regional marks.

† The average of the α-œstradiol group I.

‡ See Lipschutz and Maas (1944).

implantation of the tablets. The fibromatogenic effect was classified according to the rules already published (see especially Lipschutz and Maas 1944). The results were compared with those obtained in twenty-three animals with α-œstradiol alone and with fourteen animals into which tablets of α-œstradiol and of progesterone were implanted simultaneously (group I in table II of Lipschutz et al. 1944).

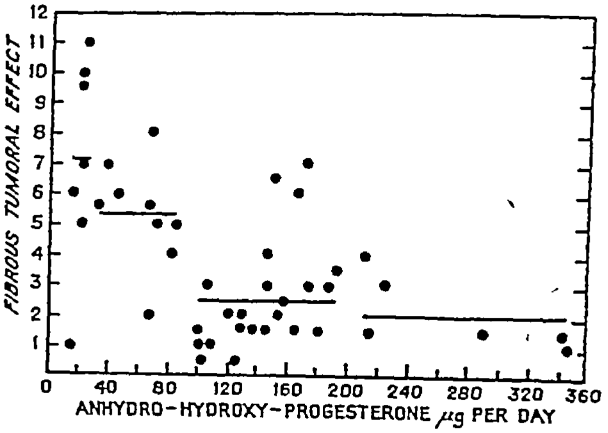
Table I (see also figure) shows that a quantity of A.H.P. (groups IIa and IIb) up to four times greater than the antifibromatogenic threshold of progesterone (group III) could not prevent œstrogen-induced fibroids. With 32–85 µg. the fibrous tumoral effect (F.T.E.) and the coefficient indicating a strong fibrous reaction (penultimate column) were as pronounced as in the absence of A.H.P. (group I). In both groups IIa and IIb no less than 50% of the animals reached the average F.T.E. of the α-œstradiol group—i.e., there was no preventive action.

Things changed considerably with quantities of 100–200 µg. of A.H.P. a day (group IIc). Though there were still three out of twenty-three animals which reached the average of the α-œstradiol group, the diminished fibrous reaction—F.T.E. = 2·5 instead of 5·3—indicates clearly that A.H.P. is antifibromatogenic. With 100–200 µg. of A.H.P. a day, or with about 5–10 times the antifibromatogenic threshold of progesterone, the "transitional zone" (Lipschutz et al. 1944) is surpassed—i.e., the antifibromatogenic action is fully evident.

TABLE II—EFFECT OF A.H.P. ON UTERINE FIBROIDS IN GUINEAPIGS

Group	No. of animals	No. of animals with uterine bleeding	No. of animals with uterine fibroids	Average fibrous uterine reaction*	Average weight of uterus (g.)	Range of weight of uterus (g.)
I	23	5	18	1·25	4·9	2·7–12·0
IIa	7	A.H.P. 0	3	0·50	4·2	2·2– 7·0
IIb	9	0	3	0·23	4·0	2·5– 6·7
IIc	23	0	3	0·15	4·0	2·2–10·0
IId	6	0	0	0	3·0	2·0– 5·7
III	14	Progest.- 0	1	0·1	3·0	1·7– 5·1

* Sum of the uterine marks of the whole group divided by number of animals in the group.



Fibrous tumoral effect induced by α-œstradiol in 45 castrated female guineapigs. Various quantities of A.H.P. a day were absorbed simultaneously. Horizontal lines indicate averages of groups IIa, IIb, IIc, and IId of table I.

A further degree of preventive antifibromatogenic action was attained in group IId with quantities of A.H.P. 10–15 times the progesterone threshold (table I).

These experiments show that A.H.P. shares with progesterone the power of preventing œstrogen-induced abdominal fibroids. But the antifibromatogenic activity of A.H.P. is less than it should be if there were full concomitance between progestational and antifibromatogenic action. With 130–240 µg. of A.H.P. a day—i.e., with ten times the antifibromatogenic threshold of progesterone—there were fibroids in many of the animals. The antifibromatogenic action of A.H.P. was even less than with testosterone (Lipschutz 1944) and especially less than would have been expected because of the side-chain of two carbons at C_{17} (Lipschutz 1944).

There is still another feature of antifibromatogenic action which deserves special mention: the preventive antifibromatogenic action refers in the first place to the subserous *uterine* fibroids and to the parametric ones. In groups IIa and IIb (table II), in which the quantities of A.H.P. were still insufficient to inhibit the abdominal fibrous reaction, there was already a very pronounced diminution of subserous uterine fibroids. In groups IIc and IId uterine fibroids were absent or almost absent. The frequency of animals with a uterine fibrous reaction was with 100–191 µg. of A.H.P. a day scarcely more pronounced than in group III with small quantities of progesterone. Table II gives a comprehensive picture of the remarkable fact that the preventive action is preferably and primarily against the uterine tumours and only secondarily against the abdominal fibroids in general. This statement is of special interest so far as practical application of our results is concerned.

The differential behaviour of uterine and extra-uterine fibroids has been found with all antifibromatogenic steroids used in our work; it can be simply explained by the higher fibromatogenic threshold for uterine fibroids compared with that for extra-uterine ones. In these quantitative circumstances uterine fibroids certainly must be the first to be *prevented*. In experiments with the progesterone treatment of previously induced fibroids the differential *regression* of uterine and extra-uterine fibroids was indeed less pronounced (Lipschutz and Maas 1944).

OTHER ANTI-ŒSTROGENIC ACTIONS OF ANHYDRO-HYDROXY-PROGESTERONE

The antifibromatogenic action coincides with other anti-œstrogenic ones. The last two columns of table II show that the increase of uterine weight due to the œstrogen is in group IId partly counteracted by A.H.P. The thickening of the myometrium was less. Though polypous growth was still present it was much less than with œstradiol alone. It was the same with reference to the vascularisation of the submucosa. Consequently there was no œstrogen-induced uterine bleeding when A.H.P. was absorbed simultaneously. As shown in table II, 5 out of 23 animals with œstradiol alone bled from the uterus; there should have been uterine bleeding in about 10 out of 45 animals in group II. But bleeding was absent even in those experiments where A.H.P. was absorbed in quantities which were smaller than those necessary to prevent abdominal fibroids.

There was no masculinising action on the clitoris, which in the guineapig is very sensitive to androgens (Lipschutz 1919, 1924, Ruz 1939). The masculinising action was absent even in group IId with 210–347 µg. of A.H.P. a day, whereas with similar quantities of testosterone propionate the transformation of the clitoris into a hypospadic penis-like organ begins to be seen in 4–7 days (Ruz 1939). With A.H.P. nothing similar happened even in so long a period as three months. Our results corroborate fully the statement of Emmens and Parkes (1939) about the very small androgenic potency of A.H.P.

PROSPECTS OF CLINICAL TRIALS WITH ANHYDRO-HYDROXY-PROGESTERONE

Clinical trials with A.H.P. in cases of uterine fibroids can be recommended on the basis of our experiments.

The facts that A.H.P., unlike progesterone, is active by mouth and that there is not the slightest danger of virilisation as with testosterone give greater hopes for the successful treatment of fibroids with A.H.P. than with the two natural steroids mentioned. It is true that findings concerning the action of steroids in laboratory animals cannot be directly applied to women. According to some authorities œstrogens may play a part in the genesis of uterine fibroids in women (Hamblen 1945). But, on the other hand, we must emphasise that up till now we have been unable to induce fibroids with œstrogens in the new-world monkey (Iglesias and Lipschutz 1940), even when these animals were kept for almost three *years* in the same experimental fibromatogenic conditions under which fibroids were induced in guinea-pigs in three *months*.

Since androgens have been revealed to be so active against uterine bleeding and against fibroids, one may tentatively suggest combining in clinical trials maximal quantities of A.H.P. by mouth with the injection of small quantities of testosterone propionate or with the subcutaneous implantation of tablets sufficiently small to allow for an absorption of only non-virilising quantities of the androgen.

SUMMARY

The antifibromatogenic action of steroids and their antitumoral action in general is discussed.

Anhydro-hydroxy-progesterone (A.H.P.), a synthetic steroid active by mouth, was tested for its power to prevent œstrogen-induced fibroids in the guineapig.

A.H.P., whose progestational activity is about a tenth of that of progesterone, has been shown to be also antifibromatogenic. But the quantities of A.H.P. necessary to prevent abdominal fibroids are about fifteen times greater than the antifibromatogenic dose of progesterone, though the antifibromatogenic effect is evident with smaller quantities of A.H.P.

Uterine fibroids are more readily prevented than other abdominal fibroids.

Œstrogen-induced uterine bleeding was counteracted with quantities of A.H.P. much smaller than those necessary for obtaining an antifibromatogenic effect.

The prospects of clinical trials with A.H.P. are discussed.

ADDENDUM

On the strength of our laboratory results with different steroids and especially with progesterone in the treatment of experimental fibroids, A. L. Goodman (*J. clin. Endocrin.* 1946, **6**, 402) has tried the therapeutic possibilities of progesterone against uterine fibromyoma in women. In seven cases 10 mg. of progesterone was injected 3–6 times weekly. A decrease in the size of the tumour or of the uterus is reported in all cases; the decrease is notable as early as 1–3 weeks after beginning the treatment. In less than 2 months the decrease was to $^1/_4$–$^3/_4$ of the original size. In one case the tumour mass "appeared to be completely gone."

This investigation has been aided by grants from the Jane Coffin Childs Memorial Fund for Medical Research, the Rockefeller Foundation, and the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation. Acknowledgment is made by A. Lipschutz for the Charles L. Mayer Award, 1944, of The National Science Fund of the National Academy of Sciences of the U.S. Our thanks are due to Dr. E. Oppenheimer, of Ciba Pharmaceutical Products, Summit N.J., for a generous gift of steroids.

REMEDIAL CORRECTION OF VALGUS FOOT STRAIN BY FOOT PRONATION EXERCISE

E. T. BAILEY
M.B. Lond., F.R.C.S.
SURGEON, FRACTURE "A" DEPARTMENT

B. S. HARRENS
SENIOR PHYSICAL TRAINING INSTRUCTOR

NORTHERN HOSPITAL, WINCHMORE HILL

THE normal foot has been aptly compared to a tripod balanced evenly beneath the leg, with the os calcis in line with the astragalus and tibia. The maintenance of this balance depends on the ability of the foot to bring the head of the first metatarsal to the ground by adequate foot pronation. Should this pronation be deficient, the first metatarsal can only be brought down by a tilting of the whole foot outwards at the subastragaloid joint. This at once produces the characteristic appearance of "flat-foot," with valgus deviation of the foot as a whole and of the os calcis in particular. In such a position of imbalance it is not surprising that symptoms of foot and leg strain appear with rapid fatigue of muscles working at a mechanical disadvantage.

Restoration of normal foot balance with adequate foot pronation should therefore be the aim of treatment; and, though corrective osteotomy of the first metatarsal may be necessary in certain cases of congenital abnormality, it was felt by us that remedial treatment specifically directed to foot pronation could bring about the desired result. With this object in view, one of us (B. S. H.) has designed the foot corrector apparatus illustrated which ensures maintenance of the correct position of the os calcis during pronation exercises in a manner which is not possible with orthodox routine foot exercises.

The apparatus (fig. 1) consists of a T-shaped wooden

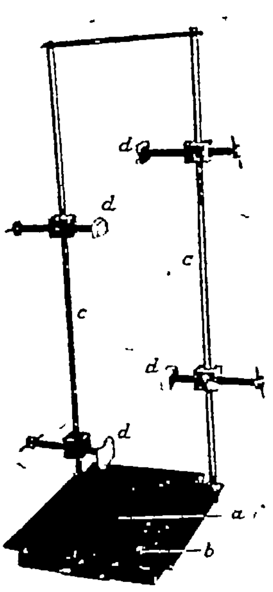

Fig. 1—The Harrens foot corrector: (a) T-piece with roller; (b) wooden base; (c) vertical rods; (d) metal plates.

foot-piece with the stem in the form of a roller (*a*) mounted upon a wooden base (*b*), from the sides of which arise two vertical adjustable metal rods (*c*). A top cross-bar unites the rods, each of which carries two sliding padded metal plates (*d*) for application to the heel and leg. Fig. 2 shows a patient seated with the leg vertical and the outer border of the foot resting on the T-piece. Four padded plates are in position, one on each side of the heel, one on the inner aspect of the leg, and one on the outer side of the thigh immediately above the knee. Movement can take place now only in the forefoot, which is actively pronated by the patient until the head of the first metatarsal can be brought down over the roller to touch the wooden base, as shown in fig. 3, which illustrates the degree of pronation present in the normal foot.

The use of two plates is not essential to maintain the position of the os calcis, which can in most cases be effectively controlled by a single plate on the outer side of the heel, provided the leg plate is applied well down the inner side of the leg about 2–4 in. above the ankle.

The apparatus has now been in constant use for eighteen months and has been found capable of correcting pronation deficiency of up to 30° in about three weeks. The pronation exercise is combined with other recognised foot exercises and physiotherapy, and is supplemented in most instances by wedging of the inner side of the heels of the boots or shoes.

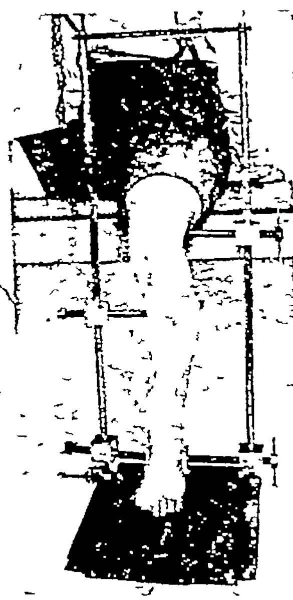

Fig. 2—Plates holding foot and leg in correct position, outer border of foot resting on roller.

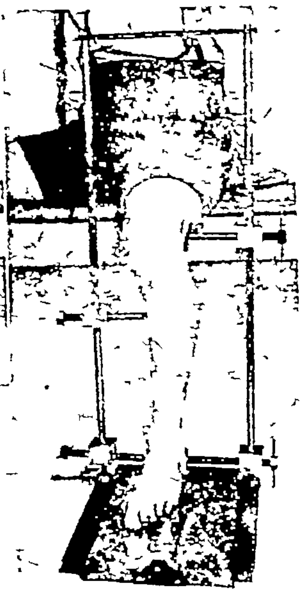

Fig. 3—Foot pronated.

The types of case for which the foot corrector has proved of value are: (1) simple valgus strains and early flat-foot in children and adults; (2) foot re-education after immobilisation in plaster; and (3) fractured os calcis.

Pronation deficiency following immobilisation in plaster can be minimised by taking care to avoid inversion of the foot and to see that the foot is pronated in the plaster as much as is practicable. The os calcis group of cases have proved more satisfactory than was expected and have in most cases been prevented from developing the all too common painful strain below the external malleolus.

We are indebted to the London County Council for the illustrations and for the supply of the foot corrector, which has been manufactured for us by Messrs. Masters & Sons, 240, New Kent Road, London, S.E.1, from whom it is obtainable.

Preliminary Communication

"PELLAGRAGENIC" ACTIVITY OF INDOLE-3-ACETIC ACID IN THE RAT

Krehl and co-workers[1] have shown that rats fed on a low-protein, low-tryptophane diet, containing 40% of maize, stop growing. Normal growth was restored by the addition of nicotinic acid or tryptophane to this diet. Woolley[2] found that 3-acetyl-pyridine produced in mice and rats a depression of growth which could be counteracted by either nicotinic acid or tryptophane. In search for a similar antivitamin in maize he has recently obtained a potent extract which was "pellagragenic" to mice in amounts of 1 mg. per 100 g. of diet.

We have been investigating the reasons why maize produces such a deficiency in rats, having particular regard to possible defects in the metabolism of tryptophane. Now, maize is known to be a rich source of indole-3-acetic acid (heteroauxin). Yellow maize meal contains, according to Haagen-Smit et al.,[3] 20 mg. per kg., or, according to Berger and Avery,[4] 100 mg. of indole-3-acetic acid per kg.; it is present largely in the form of a precursor which can be converted into indole-3-acetic acid by mild alkaline or enzymic digestion. For a diet containing 40% of maize meal the above figures correspond with 0·8 mg. and 4·0 mg. of indole-3-acetic acid per 100 g. of diet respectively.

In our experiments young rats of 60 g. weight all gained weight steadily on a purified diet containing 10·5% casein as the sole source of protein, and administration of nicotinic acid or tryptophane did not increase the growth-rate significantly. However, of 32 rats fed on a similar diet supplemented with 1·5 mg. of indole-3-acetic acid per 100 g. of diet, 19 rats showed a severe depression of growth. Of these 19 rats, 9 were dosed either with 1 mg. of nicotinic acid or with 20 mg. of tryptophane per day: this treatment in all cases effected a cure, while the remaining 10 rats which were left undosed as controls did not recover (see table).

The effect of indole-3-acetic acid was similar to that produced by the addition of whole maize meal (40%) to the diet. Of 33 rats fed on the maize-meal diet, 29 showed a severe depression of growth which could always be cured either by nicotinic acid or tryptophane. On a high-protein diet (20% casein) neither maize meal nor indole-3 acetic acid was effective in stopping growth.

4. Berger, J., Avery, G. S. jun. *Ibid*, 1944, 31, 199.

EFFECTS OF TREATMENT *

Diet	No. of rats	Average weekly gain in weight *before* treatment (g.)	Treatment	Average weekly gain in weight *after* treatment (g.)
10 5 % casein	4	15	—	—
	4	—	Nicotinic acid, preventive	18
	4	—	Tryptophane, preventive	16
10·5 % casein + indole-3-acetic acid	10	5	—	—
	7	3	Nicotinic acid, curative	11
	2	0	Tryptophane, curative	19
7 % casein + 40 % maize	22	4	—	—
	4	2	Nicotinic acid, curative	25
	3	2	Tryptophane, curative	13

* Basal diet: 3 % cotton-seed oil, 5 % salt mixture, 0 15 % cystine, casein as shown above, and sucrose ad 100. In diets containing yellow maize meal, the oil, salts, and cystine content were reduced by 40 %. The protein content of all the diets was about 10·5 %. Vitamin supplements as described by Black et al.,[5] omitting nicotinic acid.

Further experiments are in progress to determine *whether the "pellagragenic" effect of maize can be* attributed entirely to its high "auxin" content, relative to its low tryptophane and nicotinic-acid content.

Reviews of Books

Actions of Radiations on Living Cells

D. E. LEA, M.A., PH.D., Prophit student of the Royal College of Surgeons, formerly fellow of Trinity College, Cambridge. London: Cambridge University Press. Pp. 402. 21*s.*

THE greater part of this good book is occupied by an account of the effects of radiations (mostly X and *gamma) on viruses and on the genes and chromosomes* of higher cells; this happens to be the field where Dr. Lea's own experimental and theoretical work has taken him and for which he is widely known. Exactly how *cellular death is brought about by X and gamma rays* is not yet known, but he discusses the question in detail, especially the so-called target theory, defined as follows:

> "When the biological effect observed is due to the production of ionization in some particular molecules, as in the induction of gene mutations, or is due to the passage of an ionizing particle through some particular structure, *as in the induction of chromosome breakage*, it is possible to calculate the size of the molecule or structure involved from a knowledge of the proportion of the organisms irradiated which are affected by a given dose or radiation. It is further *possible to predict the variation of ionic* efficiency of different radiations in producing effects of this sort. The interpretation of biological effects of radiation along these lines has become known as the *target theory*."

It is perhaps not unfair to say of this theory that while it does help towards explaining the way in which differing ionic efficiencies are linked with different radiations, it *leaves many phenomena quite unexplained.*

Many readers will welcome the full account of genetic effects and the chromosome structural changes set up by radiation. There is much discussion at present among radiologists as to whether the *mutations set up in* drosophila have any practical bearing on man. Is there any considerable chance that radiologists in the course of their work (which, however carefully carried out, does involve some degree of exposure) suffer *mutational* changes? Unfortunately nearly all of the mutations seen in drosophila appear to be regressive. With radiation work extending on all sides it is inevitable that this subject will be widely discussed in all its bearings. *Cosmic radiation, it seems, is insufficient in intensity to* account for the spontaneous mutations known to occur without apparent cause; we must look elsewhere.

Throughout the book the outlook is *quantitative.* It will appeal to a growing body of people who see radiation not only as benign but sometimes as deadly. Though Dr. Lea does not mention it, his text makes it clear that protective methods will have *to be elaborated to* cope with the growing use of this agent.

L'anémie infectieuse.

G. HEMMELER, privat-dozent, University of Lausanne. Basle: Schwabe. Pp. 76. Sw. fr. 5.

THIS monograph is an attempt to amplify the scanty sections in most textbooks on the subject of anæmia in *infectious disease.* Details are given of anæmia occurring in typhoid fever, bacterial endocarditis, rheumatoid arthritis, and other conditions. Complete records are given of 25 selected patients; besides full blood-counts, sternal marrow punctures were carried out, the reticulocyte changes followed, and estimations made of the serum iron. Dr. Hemmeler notes that the severity of the anæmia is directly proportional to the severity of the fever, the acceleration of the blood-sedimentation rate, and the leucocytosis. The anæmia is normochromic and reticulocytes are low. The bone-marrow is less cellular than normal and the erythroblasts are mainly basophilic, few oxyphilic. The serum iron is normal or low. When the infection dies down there is a spontaneous remission of the anæmia, independent of treatment, accompanied by a small reticulocytosis and increased cellularity of the bone-marrow with accelerated erythroblast maturation. Dr. Hemmeler thinks that the anæmia *arises from the failure of a depressed* erythropoietic marrow to make up the loss of red cells due to the increased rate of hæmolysis that accompanies fevers. He finds no evidence that it is due to iron-deficiency, and attributes it to toxic depression of erythropoiesis. He makes the useful point that iron and liver are useless for treating these patients; blood-transfusion should be undertaken whenever the hæmoglobin falls below 60%.

A good deal of valuable information is presented in this pamphlet; but, as in other Swiss writings at present, there is little evidence of contact with Anglo-American *literature since 1939, and no reference to the* work on the disturbance of hæmoglobin formation in infectious diseases.

The Outlook of Science

Modern Materialism. (2nd ed.) R. L. WORRALL, M.B. Sydney. London: Staples Press. Pp. 191. 12*s.* 6*d.*

THOUGH useful, this book is not in the front rank with Maudsley's *Organic to Human* and Bosanquet's *Meditatio Medici* (neither of which appears in the bibliography appended to this work). The author's vision is fairly clear, but he wears glasses *which are misty* in spots. As a champion of dialectic materialism he looks forward to a time when, under a world government *based on* genuine democracy (undefined), science will satisfy the essential wants of all; and having demolished Bishop Berkeley, Bertrand Russell, Sir Oliver Lodge, Eddington, J. S. Haldane, Sir James Jeans, Lancelot Hogben, and A. N. Whitehead, he takes his stand on Lenin, Marx, Engels, and Freud. Besides science, he discusses philosophy, *religion*, and art. Religion, he says, is founded on idealism, the opposite of materialism; therefore religion is an illusion. Religion is a social product and "exists today because of its value to the ruling classes of capitalist society. . . . Science and art can be considered together, in being fertile forms of human culture. Religion, however, an inevitable phase of early culture, has become sterile, and is now equally inevitably a reactionary force inimical to the welfare of *society.*" *He advocates* a "revolutionary transformation" of society (and points to the U.S.S.R.), without which the successful future of science is impossible. The present subservience of science to politics is *illustrated, he believes,* by the atom bomb. Few will want to follow him all the way but he has his stimulating moments.

Messrs. *H. K. Lewis, Gower Street,* London, *W.C.1,* are the English agents for the Year Book of Neurology, Psychiatry and Endocrinology which was reviewed in our issue of Sept. 21.

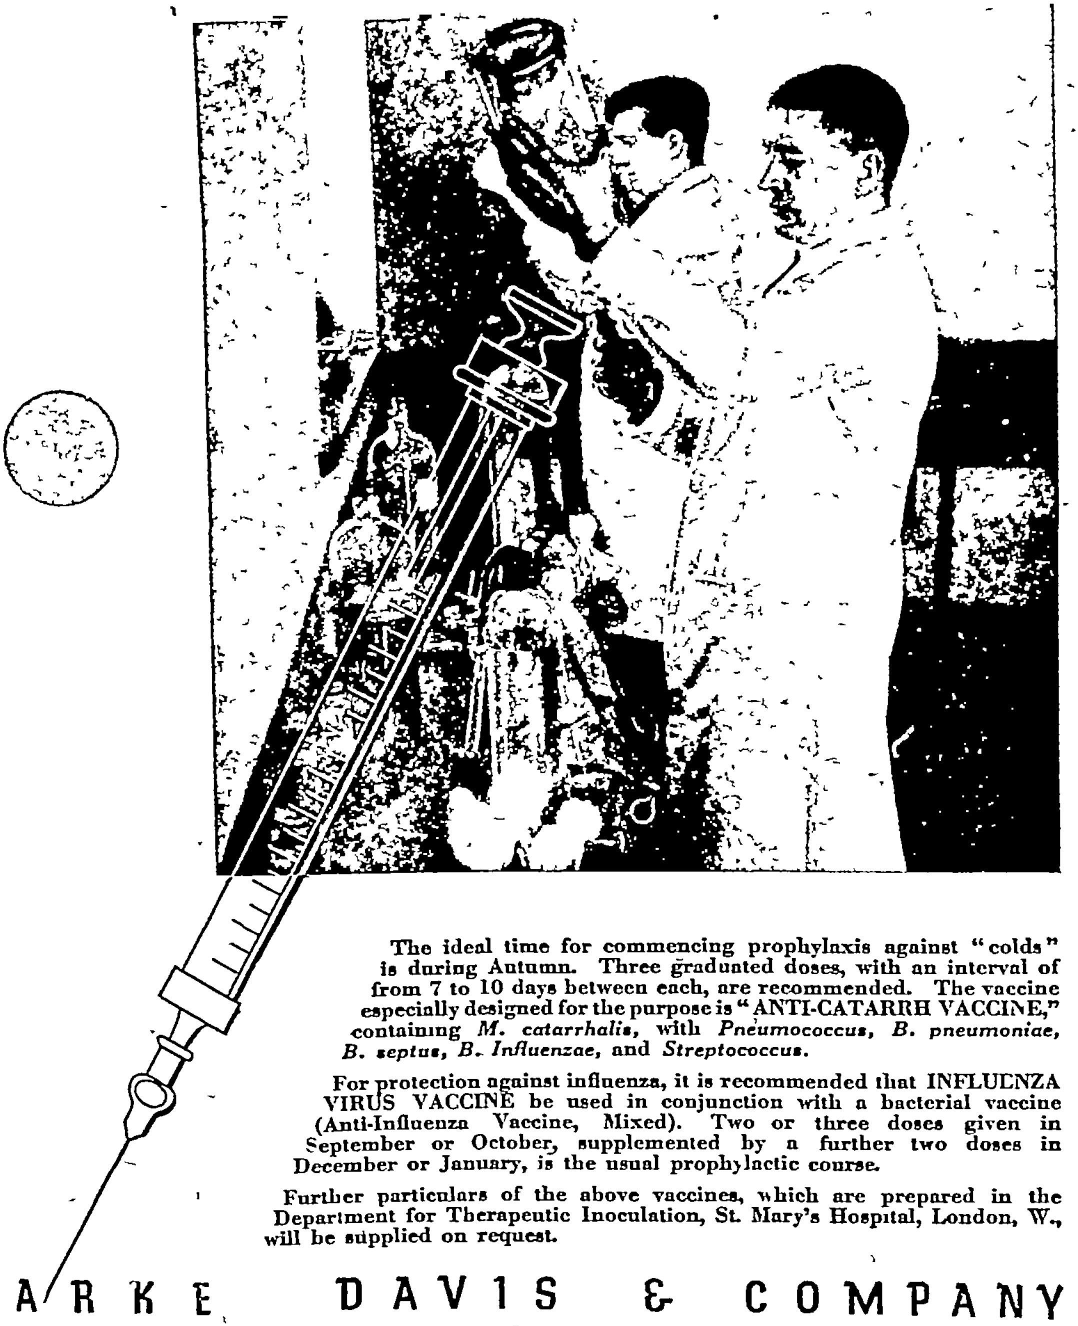
ST. MARY'S HOSPITAL
VACCINES
FOR RESPIRATORY AFFECTIONS



The ideal time for commencing prophylaxis against "colds" is during Autumn. Three graduated doses, with an interval of from 7 to 10 days between each, are recommended. The vaccine especially designed for the purpose is "ANTI-CATARRH VACCINE," containing *M. catarrhalis*, with *Pneumococcus*, *B. pneumoniae*, *B. septus*, *B. Influenzae*, and *Streptococcus*.

For protection against influenza, it is recommended that INFLUENZA VIRUS VACCINE be used in conjunction with a bacterial vaccine (Anti-Influenza Vaccine, Mixed). Two or three doses given in September or October, supplemented by a further two doses in December or January, is the usual prophylactic course.

Further particulars of the above vaccines, which are prepared in the Department for Therapeutic Inoculation, St. Mary's Hospital, London, W., will be supplied on request.

A non-greasy ANALGESIC OINTMENT

PRODUCT OF THE GLAXO LABORATORIES

Relief of pain and discomfort within a few minutes and lasting two hours or more is obtained after the simple, direct application of 'Anethaine' Ointment to the skin or mucous membrane.

'Anethaine' Ointment is non-greasy and is readily removed with water from the skin or clothing. It contains 1.0 per cent. of the fat-soluble base of amethocaine hydrochloride.

For the relief of pain in haemorrhoids and skin diseases generally. Many other uses will suggest themselves to doctors.

THE LANCET

LONDON: SATURDAY, OCT. 5, 1946

Over to the Lords

TAKEN by and large, Mr. BEVAN's handling of the National Health Service Bill in the House of Commons was masterly, and many of those who a few months ago were strongly antagonistic now understand the strength of the Government case. There are grounds therefore for his hope that, though the armies are still arrayed on the battlefield, they are becoming increasingly listless; and the president of one of the Royal Colleges did well last week to direct attention to the peace conferences which must soon follow. Nevertheless a further chance remains for amending the text of the Bill, during the debate which opens in the House of Lords next Tuesday, and it would be a pity if this discussion were to be a mere formality. Much in the scheme remains highly debatable, and the Government should welcome any attempt to make a good Bill better—to correct weaknesses that might eventually prove its undoing. Uneasiness over several of its provisions is still felt by those most anxious for its success.

Despite all the Minister's explanations, we are still uncertain whether the degree of autonomy granted to hospital management committees is going to be sufficient, in the long run, to induce able men and women to serve them devotedly. The misgivings felt on this score were cogently set out in our columns a few weeks ago [1] by a correspondent who rightly pointed out that on the management committee "more than on any other body or person—the Minister included—will depend whether a hospital functions in an efficient and humane manner." Decentralisation of powers, as Mr. BEVAN recognises, is the main safeguard against a uniformly second-rate service, and he has accepted the plea made in our first comment on the Bill [2] that hospital management committees should at least have their own pocket-money and be able to accept gifts. He has in fact promised that the regulations will ensure that adequate powers are delegated by the regional boards to the committees. But if that is his intention, is it necessary that the Bill should specifically lay down that the regional boards shall be the bodies to appoint officers, to maintain premises, and "to acquire on behalf of the Minister and to maintain equipment, furniture and other movable property required for the purposes of any such hospital"? Are the boards really going to appoint subordinate personnel, to paint the building, and to mend broken tables and chairs? In general Mr. BEVAN has sought to leave himself and his successors a free hand, so that where experience reveals a mistake it will be possible to modify the Bill by regulation, without new legislation. Can he be sure that the statutory assignment of these powers to regional boards—which, especially if there are only 16–20 large regions,[3] are capable of becoming pieces of bureaucratic machinery [4]—will not need modification? Some hold that in practice it will seriously limit the devolution of responsibility which all desire. If the policy is to delegate to local management committees whatever powers may be found necessary for their functional health, would it not be wise at this stage to omit these particularising subsections? To some extent the scheme is admittedly experimental, and it might be best to say quite simply that the regional boards and the hospital management committees shall exercise such powers as are respectively delegated to them by the Minister. Though nebulous, this would at any rate not be misleading.

Another possible source of future trouble is the wide power of direction given to the Minister in connexion with hospital and specialist services. As we have already remarked,[5] this power is not restricted to the administrative as distinct from the professional sphere. When Mr. BEVAN was challenged on the point in the standing committee he gave an assurance that he would not be so foolish as to meddle in professional matters; and this assurance, since repeated, undoubtedly represents his attitude correctly. Yet the profession, with its experience of directions of a semitechnical character that have issued from the Emergency Medical Service, cannot be so easily satisfied. There will be—there ought to be—medical officers in the Ministry of Health anxious to secure widespread adoption of modern techniques. Will their ideas emanate from Whitehall with all the authority of directions made in the name of the Minister, binding even on the regional boards? That is the question, and Mr. BEVAN did not really answer it. We hope therefore it is not too late to incorporate in the Bill a formula making it clear how far the Minister's power of direction legitimately extends. This should not be beyond the wit of legal draftsmen, for the distinction between administrative and professional matters is neither new nor hopelessly subtle: it is commonly respected in the hospital world today. The fact surely is that the simple wording of the Bill as it stands is too simple to meet the complexity of the undertaking. For simplicity's sake the distinction between the administrative and professional responsibility in respect of the hospital and specialist services has been allowed to slip into the background. It would be a pity indeed if it were to become blurred, for the ultimate consequences could be disastrous to professional freedom.

A related question, calling for legal debate, is whether practitioners whose conduct the Minister finds harmful to the National Health Service should have a right to appeal from his decision to a court of law. The procedure as now laid down is that any complaint is made to the local executive council and is examined in the first place by a purely medical body, the council's medical subcommittee. A decision on the complaint is then reached by the council, half of whose members are doctors, dentists, and pharmacists. If the defendant practitioner is dissatisfied with the council's verdict he can appeal to a tribunal of three persons, of whom the chairman is appointed by the Lord Chancellor. If again unsuccessful he can appeal to the Minister himself, who is the person finally responsible for the well-being of the service. But only if one of these authorities appears to have

anæsthesia have been tried. Hamilton Bailey[6] advocates a local anæsthetic plus 'Pentothal sodium,' and his advice is followed by many resident surgical officers; this method has the advantage that a long anæsthesia is not maintained for what is really a short operation. Recently curare has proved useful in these cases. As Mimpriss and Etheridge[7] remark, the incidence of chest complications is largely determined by the state of the peritoneal cavity after operation. We know that the peritoneal cavity is usually sterile for about twelve hours after a perforation. The time of the previous meal, the presence of chunks of food, beer, and particularly the barium of an opaque meal—all these are factors influencing the prognosis which must be carefully weighed before deciding against operative treatment. Not enough has yet been heard of the use of penicillin in peritonitis to enable its value to be judged. If we are inclined to give credit to the sulphonamides for the very satisfactory Newcastle figures we must not forget that Gilmour and Saint's series was published in the days before sulphonamide therapy. Taylor's patients had neither sulphonamides nor penicillin. We know that the streptococcus is the usual infecting organism, and penicillin systemically administered does penetrate into the peritoneal cavity. This is a large cavity, so large doses of penicillin may be required. Crile[8] has recently pointed out that in generalised peritonitis of appendicular origin, where there is a mixed infection, extremely large doses of penicillin are necessary; he has advocated 100,000 units every two hours for four to six days. Generalised peritonitis following perforation is an almost certainly fatal complication, and there is need for more work on this subject. Taylor has pointed to one way of preventing this disaster—turn the tap off, put the stomach-tube down, and give the peritoneum a reasonable chance of exercising its natural function of limiting infection.

Pilonidal Sinus

During the war pilonidal sinus proved, for so small and undignified a lesion, a remarkable waster of man-power. Thus, according to Holman,[1] it cost the United States Navy 359,209 "sick days" in the two years 1942 and 1943. A peripatetic correspondent recalls that so striking was the tendency for riding in hard-seated vehicles to exacerbate the pilonidal sinus that it came to be familiarly called the "jeep disease." At first sight the treatment of a small discharging sinus or an apparent boil posterior to the anus seems a simple problem; but it is one which, from delayed healing or recurrence, has baffled the ingenuity of many surgeons.

The pilonidal sinus, or postanal dermoid, has hitherto been accepted as an infected embryological remnant. Two main theories of origin have been held—one that the sinus arises from imperfect separation of the hind end of the neural tube from the ectoderm, and the other that it is a sequestration dermoid formed during fusion of the ectoderm growing in towards the midline. There is proof that both these mechanisms do sometimes give rise to dermoids in this region, but Mr. Patey and Professor Scarff, elsewhere in this issue, challenge the view that all, or even most, pilonidal sinuses are of embryological origin. They have been struck by the number of excised specimens in which no epithelial lining can be detected, and by the rarity of sebaceous glands and even of hair follicles. They have found little difference in the histology of a primary and a recurrent sinus, and they think that most examples are acquired infective lesions, probably originating from puncture of the skin by a hair. This belief was strengthened by their encountering a pilonidal sinus in the hand of a barber and finding that puncture of the skin by hairs is by no means an uncommon cause of minor sepsis of the hand in barbers. The idea of a hair causing a puncture wound must be novel to many, but it seems to offer a reasonable explanation of pilonidal sinuses. Any puncture in an area so heavily infected, so humid, and so constantly subjected to friction and movement as the natal cleft, would tend not to heal.

Conflicting theories of ætiology seldom have an immediate practical impact on patients. What is distressing about pilonidal sinus is the extreme divergence of views on the best method of treatment, because it indicates that no method is really satisfactory. Every kind of operation has been tried, from mere evacuation of pus to wide ablation of the sinus and its surroundings. Most surgeons excise en bloc and suture the resulting wound, but some excise and leave healing to occur by granulation—a process tedious to both patient and doctor. Even among those who excise and suture, there is no unanimity on technique, as we may see from two recent papers from America, both reporting series of at least 100 cases. Larsen[2] believes in wide excision of skin, no undercutting of skin edges, and approximation of fat and skin only, with as many layers of cotton sutures as can conveniently be inserted. Larkin,[3] on the other hand, advises sparing excision of the skin and wide undermining of the flaps, and he approximates the wound edges with a single layer of wire sutures which pierce skin, fat, and sacrococcygeal fascia. Larkin secures hæmostasis by catgut ligatures, Larsen uses cotton, while Holman stops bleeding by pressure, because he holds that the small tags of dead tissue caused by clamping and tying vessels are prejudicial to healing.

It seems as if results must depend, as in so many surgical procedures, on the man rather than the method. One can however state in general terms the present trends in the treatment of pilonidal sinus. First, radical operation should be deferred if the sinus is in a state of acute inflammation. When the latter has subsided the whole sinus must be excised so that the body starts its healing processes with an aseptic wound; and to achieve this it is not necessary to sacrifice much skin. The wound edges should usually be sutured, because healing by granulation takes a long time and often leaves a scar whose skin is ill adapted to sustain the chafe and pressure inherent in its position. Every effort must be made to prevent secondary infection: hæmostasis should be carefully secured with as few and as fine ligatures as possible, the dead space must be obliterated (for which purpose each surgeon must select

exceeded its legal powers, or to have acted improperly, can he seek help from an outside court. Provided the morale of the profession and the service is high, these arrangements should work well in practice; and Mr. BEVAN has substance for his contention that the High Court is not the right kind of body to say whether a doctor has been reasonably efficient. Nevertheless under the new régime expulsion from the public service will be an extremely serious penalty, and it seems contrary to the principles of justice that sentence should be passed by the Minister who may be indirectly responsible for the accusation It was to overcome this objection, of course, that the tribunal was inserted between the local executive council and the Minister; but two of the three members of this tribunal are to be chosen by the Minister himself. The arrangements are in fact of the "quasi-judicial" nature which Sir HENRY SLESSER[6] and other eminent lawyers view with alarm, and there is far more in question than administrative convenience.

[3] Larkin, L. C. *Surg. Gynec. Obstet.* 1946, 82, 694.

All these are matters that the Lords are well fitted to elucidate. It is their function to take a long view, and we trust that discussion will not be frozen by too ready acquiescence, on either side of the House, in the Bill as it stands.

Perforated Peptic Ulcer

"THIS is one of the most serious and overwhelming catastrophes that can befall a human being. Unless surgical measures are adopted early, the disease hastens to a fatal ending in almost every instance." In the decades since MOYNIHAN spoke these words, early operation for the perforated peptic ulcer has seemed to be as right and natural as the surgeon's gloves. So it comes as a shock to find HERMON TAYLOR, in the article we published last week, declaring that conservatism has a place—he would even give it pride of place—in the treatment of perforation. He puts forward a convincing series of 28 cases treated by conservative methods with 4 deaths; 3 from conditions unrelated to the treatment, and only 1 in which, as he admits, operation might have made a difference. TAYLOR has turned away from immediate laparotomy, first, because he often found at operation that the perforation was already partially sealed and nature was clearly capable of completing the process. The peritoneal cavity, it appeared, could cope with a considerable quantity of infective fluid, provided that continued gross flooding from the perforation site was controlled by aspirating the stomach. Secondly, he had found that the mortality with operation was high, largely because of chest complications. Thirdly, many of these patients, because of bronchitis, severe hypertension, or myocardial failure, came in the "poor risk" class, where even a minor surgical procedure was hazardous.

These results must be studied in conjunction with those of operation. TAYLOR's cases were mostly early perforations, the delay before admission to hospital exceeding six hours in only 3—a fact that speaks well for the diagnostic alertness of the general practitioners in the district. Is operation really hazardous in such early cases? GILMOUR and SAINT[1] record 51 cases operated on within twelve hours of perforation with 1 death; SOUTHAM[2] 34 cases of duodenal perforation operated on within twenty-four hours with no deaths. MAINGOT[3] gives the mortality as 2–6%. Unfortunately it is the practice to group together all perforations, and the overall mortality figures for surgical treatment thus seem high. Even so HOUSTON,[4] in a recent analysis, gives the Newcastle figures for 1943 as 184 cases with 8·2% mortality; for 1944 as 190 cases with a 6·3% mortality Surgery has not a great deal to be ashamed of with such figures.

These comparisons in no way detract from the value of the information to be drawn from TAYLOR's experience. It emphasises the need for emptying the stomach as soon as possible after the perforation has been diagnosed; the small Ryle tube is not enough and it is a useful tip to give an amethocaine lozenge to facilitate the passage of a large tube. Morphine should be given as soon as possible and the patient "made comfortable." TAYLOR *neither advocates nor condemns* the Fowler position, and one may assume that the half-sitting position is the most comfortable one; it is noteworthy that none of his cases developed a subphrenic abscess. His results have shown that where the diagnosis is in doubt, or where the patient's poor general condition or the lack of a surgeon prohibits operation, we have a method of treating the early case with a reasonable chance of success. TAYLOR agrees that when there has been a recent large meal with a likelihood of extensive spilling into the peritoneal cavity, and when the patient comes "too late," surgery is indicated. It must not be forgotten that the perforation is usually an emergency, coming under the care of the house-surgeon or R.S.O., whereas conservative treatment obviously requires an experienced clinical eye; it might therefore be hazardous to advocate this treatment as the routine, even for the early case. Most surgeons, too, will find operation less nerve-racking than a policy of wait and see. One surgeon with a considerable experience of conservative treatment has remarked: "I agree conservative treatment works, but I have given it up. I have had too much anxiety with the early convalescence of these cases." The conservative method suggests itself as particularly suitable for the aged. TANNER,[5] in a series of 16 perforations in people over sixty, had 10 deaths after operation—apparently a formidable mortality. Of 8 cases operated on under twelve hours, however, 6 made a complete recovery, and the 2 deaths were due to bronchopneumonia and cerebral thrombosis; in TANNER's view failure to send the patient to the surgeon early was mainly responsible for the high mortality, and in TAYLOR's 6 cases in men over sixty the only death was in a patient who had perforated twenty-four hours before admission.

The operation for perforation is usually simplicity itself. A midline incision seems to be most popular, though a right rectus muscle incision is used by some surgeons because there is an 8 to 1 chance of the perforation being duodenal. In view of the chest complications which commonly follow the perforated ulcer, and the difficulty of attaining adequate relaxation of the abdominal wall, various methods of anæsthesia have been tried. Hamilton Bailey[6] advocates a local anæsthetic plus 'Pentothal sodium,' and his advice is followed by many resident surgical officers; this method has the advantage that a long anæsthesia is not maintained for what is really a short operation. Recently curare has proved useful in these cases. As Mimpriss and Etheridge[7] remark, the incidence of chest complications is largely determined by the state of the peritoneal cavity after operation. We know that the peritoneal cavity is usually sterile for about twelve hours after a perforation. The time of the previous meal, the presence of chunks of food, beer, and particularly the barium of an opaque meal—all these are factors influencing the prognosis which must be carefully weighed before deciding against operative treatment. Not enough has yet been heard of the use of penicillin in peritonitis to enable its value to be judged. If we are inclined to give credit to the sulphonamides for the very satisfactory Newcastle figures we must not forget that Gilmour and Saint's series was published in the days before sulphonamide therapy. Taylor's patients had neither sulphonamides nor penicillin. We know that the streptococcus is the usual infecting organism, and penicillin systemically administered does penetrate into the peritoneal cavity. This is a large cavity, so large doses of penicillin may be required. Crile[8] has recently pointed out that in generalised peritonitis of appendicular origin, where there is a mixed infection, extremely large doses of penicillin are necessary; he has advocated 100,000 units every two hours for four to six days. Generalised peritonitis following perforation is an almost certainly fatal complication, and there is need for more work on this subject. Taylor has pointed to one way of preventing this disaster—turn the tap off, put the stomach-tube down, and give the peritoneum a reasonable chance of exercising its natural function of limiting infection.

Pilonidal Sinus

During the war pilonidal sinus proved, for so small and undignified a lesion, a remarkable waster of man-power. Thus, according to Holman,[1] it cost the United States Navy 359,209 "sick days" in the two years 1942 and 1943. A peripatetic correspondent recalls that so striking was the tendency for riding in hard-seated vehicles to exacerbate the pilonidal sinus that it came to be familiarly called the "jeep disease." At first sight the treatment of a small discharging sinus or an apparent boil posterior to the anus seems a simple problem; but it is one which, from delayed healing or recurrence, has baffled the ingenuity of many surgeons.

The pilonidal sinus, or postanal dermoid, has hitherto been accepted as an infected embryological remnant. Two main theories of origin have been held—one that the sinus arises from imperfect separation of the hind end of the neural tube from the ectoderm, and the other that it is a sequestration dermoid formed during fusion of the ectoderm growing in towards the midline. There is proof that both these mechanisms do sometimes give rise to dermoids in this region, but Mr. Patey and Professor Scarff, elsewhere in this issue, challenge the view that all, or even most, pilonidal sinuses are of embryological origin. They have been struck by the number of excised specimens in which no epithelial lining can be detected, and by the rarity of sebaceous glands and even of hair follicles. They have found little difference in the histology of a primary and a recurrent sinus, and they think that most examples are acquired infective lesions, probably originating from puncture of the skin by a hair. This belief was strengthened by their encountering a pilonidal sinus in the hand of a barber and finding that puncture of the skin by hairs is by no means an uncommon cause of minor sepsis of the hand in barbers. The idea of a hair causing a puncture wound must be novel to many, but it seems to offer a reasonable explanation of pilonidal sinuses. Any puncture in an area so heavily infected, so humid, and so constantly subjected to friction and movement as the natal cleft, would tend not to heal.

Conflicting theories of ætiology seldom have an immediate practical impact on patients. What is distressing about pilonidal sinus is the extreme divergence of views on the best method of treatment, because it indicates that no method is really satisfactory. Every kind of operation has been tried, from mere evacuation of pus to wide ablation of the sinus and its surroundings. Most surgeons excise en bloc and suture the resulting wound, but some excise and leave healing to occur by granulation—a process tedious to both patient and doctor. Even among those who excise and suture, there is no unanimity on technique, as we may see from two recent papers from America, both reporting series of at least 100 cases. Larsen[2] believes in wide excision of skin, no undercutting of skin edges, and approximation of fat and skin only, with as many layers of cotton sutures as can conveniently be inserted. Larkin,[3] on the other hand, advises sparing excision of the skin and wide undermining of the flaps, and he approximates the wound edges with a single layer of wire sutures which pierce skin, fat, and sacrococcygeal fascia. Larkin secures hæmostasis by catgut ligatures, Larsen uses cotton, while Holman stops bleeding by pressure, because he holds that the small tags of dead tissue caused by clamping and tying vessels are prejudicial to healing.

It seems as if results must depend, as in so many surgical procedures, on the man rather than the method. One can however state in general terms the present trends in the treatment of pilonidal sinus. First, radical operation should be deferred if the sinus is in a state of acute inflammation. When the latter has subsided the whole sinus must be excised so that the body starts its healing processes with an aseptic wound; and to achieve this it is not necessary to sacrifice much skin. The wound edges should usually be sutured, because healing by granulation takes a long time and often leaves a scar whose skin is ill adapted to sustain the chafe and pressure inherent in its position. Every effort must be made to prevent secondary infection: hæmostasis should be carefully secured with as few and as fine ligatures as possible, the dead space must be obliterated (for which purpose each surgeon must select

exceeded its legal powers, or to have acted improperly, can he seek help from an outside court. Provided the morale of the profession and the service is high, these arrangements should work well in practice; and Mr. BEVAN has substance for his contention that the High Court is not the right kind of body to say whether a doctor has been reasonably efficient. Nevertheless under the new régime expulsion from the public service will be an extremely serious penalty, and it seems contrary to the principles of justice that sentence should be passed by the Minister who may be indirectly responsible for the accusation. It was to overcome this objection, of course, that the tribunal was inserted between the local executive council and the Minister; but two of the three members of this tribunal are to be chosen by the Minister himself. The arrangements are in fact of the "quasi-judicial" nature which Sir HENRY SLESSER[6] and other eminent lawyers view with alarm, and there is far more in question than administrative convenience.

All these are matters that the Lords are well fitted to elucidate. It is their function to take a long view, and we trust that discussion will not be frozen by too ready-acquiescence, on either side of the House, in the Bill as it stands.

Perforated Peptic Ulcer

"THIS is one of the most serious and overwhelming catastrophes that can befall a human being. Unless surgical measures are adopted early, the disease hastens to a fatal ending in almost every instance." In the decades since MOYNIHAN spoke these words, early operation for the perforated peptic ulcer has seemed to be as right and natural as the surgeon's gloves. So it comes as a shock to find HERMON TAYLOR, in the article we published last week, declaring that conservatism has a place—he would even give it pride of place—in the treatment of perforation. He puts forward a convincing series of 28 cases treated by conservative methods with 4 deaths; 3 from conditions unrelated to the treatment, and only 1 in which, as he admits, operation might have made a difference. TAYLOR has turned away from immediate laparotomy, first, because he often found at operation that the perforation was already partially sealed and nature was clearly capable of completing the process. The peritoneal cavity, it appeared, could cope with a considerable quantity of infective fluid, provided that continued gross flooding from the perforation site was controlled by aspirating the stomach. Secondly, he had found that the mortality with operation was high, largely because of chest complications. Thirdly, many of these patients, because of bronchitis, severe hypertension, or myocardial failure, came in the "poor risk" class, where even a minor surgical procedure was hazardous.

These results must be studied in conjunction with those of operation. TAYLOR's cases were mostly early perforations, the delay before admission to hospital exceeding six hours in only 3—a fact that speaks well for the diagnostic alertness of the general practitioners in the district. Is operation really hazardous in such early cases? GILMOUR and SAINT[1] record 51 cases operated on within twelve hours of perforation with 1 death; SOUTHAM[2] 34 cases of duodenal perforation operated on within twenty-four hours with no deaths. MAINGOT[3] gives the mortality as 2–6%. Unfortunately it is the practice to group together all perforations, and the overall mortality figures for surgical treatment thus seem high. Even so, HOUSTON,[4] in a recent analysis, gives the Newcastle figures for 1943 as 184 cases with 8·2% mortality; for 1944 as 190 cases with a 6·3% mortality. *Surgery has not a great deal to be ashamed of with such figures.*

These comparisons in no way detract from the value of the information to be drawn from TAYLOR's experience. It emphasises the need for emptying the stomach as soon as possible after the perforation has been diagnosed; the small Ryle tube is not enough, and it is a useful tip to give an amethocaine lozenge to facilitate the passage of a large tube. Morphine should be given as soon as possible and the patient "made comfortable." TAYLOR neither advocates nor condemns the Fowler position, and one may assume that the half-sitting position is the most comfortable one; it is noteworthy that none of his cases developed a subphrenic abscess. His results have shown that where the diagnosis is in doubt, or where the patient's poor general condition or the lack of a surgeon prohibits operation, we have a method of treating the early case with a reasonable chance of success. TAYLOR agrees that when there has been a recent large meal with a likelihood of extensive spilling into the peritoneal cavity, and when the patient comes "too late," surgery is indicated. It must not be forgotten that the perforation is usually an emergency, coming under the care of the house-surgeon or R.S.O., whereas conservative treatment obviously requires an experienced clinical eye; it might therefore be hazardous to advocate this treatment as the routine, even for the early case. Most surgeons, too, will find operation less nerve-racking than a policy of wait and see. One surgeon with a considerable experience of conservative treatment has remarked: "I agree conservative treatment works, but I have given it up. I have had too much anxiety with the early convalescence of these cases." The conservative method suggests itself as particularly suitable for the aged. TANNER,[5] in a series of 16 perforations in people over sixty, had 10 deaths after operation—apparently a formidable mortality. Of 8 cases operated on under twelve hours, however, 6 made a complete recovery, and the 2 deaths were due to bronchopneumonia and cerebral thrombosis; in TANNER's view failure to send the patient to the surgeon early was mainly responsible for the high mortality, and in TAYLOR's 6 cases in men over sixty the only death was in a patient who had perforated twenty-four hours before admission.

The operation for perforation is usually simplicity itself. A midline incision seems to be most popular though a right rectus muscle incision is used by some surgeons because there is an 8 to 1 chance of the perforation being duodenal. Larkin,[3] on the other hand, advises sparing excision of the skin and wide undermining of the flaps, and he approximates the wound edges with a single layer of wire sutures which pierce skin, fat, and sacrococcygeal fascia. Larkin secures hæmostasis by catgut ligatures, Larsen uses cotton, while Holman stops bleeding by pressure, because he holds that the small tags of dead tissue caused by clamping and tying vessels are prejudicial to healing.

It seems as if results must depend, as in so many surgical procedures, on the man rather than the method. One can however state in general terms the present trends in the treatment of pilonidal sinus. First, radical operation should be deferred if the sinus is in a state of acute inflammation. When the latter has subsided the whole sinus must be excised so that the body starts its healing processes with an aseptic wound; and to achieve this it is not necessary to sacrifice much skin. The wound edges should usually be sutured, because healing by granulation takes a long time and often leaves a scar whose skin is ill adapted to sustain the chafe and pressure inherent in its position. Every effort must be made to prevent secondary infection: hæmostasis should be carefully secured with as few and as fine ligatures as possible, the dead space must be obliterated (for which purpose each surgeon must select

for himself from a bewildering number of suture and dressing techniques the method he thinks will best avoid "tenting" of the skin), and the surface of the wound must be kept dry. Though penicillin can usefully be employed, local implantation of the sulphonamides, particularly the less soluble ones like sulphathiazole, is liable to increase exudation and thus do more harm than good. Finally, PATEY and SCARFF, following the implications of their hypothesis, suggest that preoperative epilation of the area by X rays is likely to prove an essential part of the treatment.

Annotations

WORLD MEDICAL ASSOCIATION

IF the World Medical Association, whose formation in London last week is reported elsewhere in this issue, is to fulfil the aims that are set before it, it will need world support. Its first purpose must therefore be to attract into full membership those countries which were not represented at the meeting or which, like the United States of America, were represented only by observers. Its second purpose may well be to become a live body, sharing actively in world health organisation. Last week the sentiment seemed to be against the association's concerning itself with scientific medicine, because, according to one delegate, each country has its own academies competent for this work. On the other hand, the resolution setting out the association's functions allowed for the exchange of information between the different countries. It might be best if this clause were liberally interpreted; for, as we have lately suggested (Sept. 7, p. 352), the complexity of modern medicine calls for the closest technical understanding between all countries. The association, if it shouldered the task of promoting the exchange of scientific information, and particularly information on research, might benefit not only world medicine but the professions in the constituent countries.

CARDIOVASCULAR CHANGES IN ANÆMIA

DESPITE the fundamental relation of anæmia to the cardiovascular system, published work has been mainly concerned with particular aspects of the question, or with rare or severe disorders. In 1939 Ellis and Faulkner[1] reviewed the effects of anæmia on the hearts of 47 patients, but these were of all ages, and, as the investigators themselves pointed out, degenerative cardiovascular changes in the elderly undoubtedly vitiated the results. In this country Alastair Hunter[2] has now made a similar study of 34 patients, excluding all those in whom factors other than anæmia were likely to influence the cardiovascular findings.

Dyspnœa, palpitation, and cardiac pain were noted in that order of frequency, all three symptoms being related to exercise and relieved by rest. Dyspnœa was never orthopnœic or paroxysmal. Anginal pain occurred in 8 patients, but only 2 had radiation to the arm or back, while 4 others had tightness of the chest. Hunter is sure that anæmia alone can cause cardiac pain, and he suggests that "in any woman under forty, without hypertension, and complaining of cardiac pain, the cause may be an unrecognised anæmia." Hypertensives were excluded; the average initial blood-pressure was 135 mm. Hg systolic, and 70 mm. Hg diastolic. Treatment was followed by a rise in both the systolic and, more especially, the diastolic pressures; in 3 patients the rise was considerable, amounting in 2 ultimately to hypertension. In 8 patients a third heart sound, classified as abnormal under Evans's recent scheme,[3] was heard. Systolic murmurs were present in 30 of the 34 patients; 9 had apical murmurs only, 20 had pulmonary, or pulmonary and aortic, and 1 had a pulmonary only. Of these, 2 had additional murmurs, early diastolic and presystolic respectively, which disappeared with treatment. Only 4 had no murmurs. No correlation could be demonstrated between murmurs and cardiac enlargement. Murmurs, although disappearing after treatment, did not do so with anything like the rapidity of the enlargement. Heart-size, which was assessed radiologically, was definitely increased in 12, and equivocally so in 6; size regressed with treatment in 11, improvement being maximal in the early weeks. There was no direct relation between enlargement and the severity of the anæmia, although the duration of the latter seemed a possible factor. Of 25 patients who had an electrocardiogram, 5 showed minor changes, 2 of these being gross; 2 of the 5 reverted to normal after treatment.

These are interesting findings, for the signs and symptoms described here have often in the past led to an erroneous diagnosis of heart-failure. The dyspnœa, palpitation, œdema, cardiac pain, and murmurs may all result directly from different qualitative changes in the blood. Cardiac enlargement, Hunter considers, is caused by a dynamic disorder of the circulation, although, with excessive physical demands or pre-existing cryptic cardiac disease, true failure may supervene. Sharpey-Schafer[4] has suggested that in severe chronic anæmia the raised venous pressure, which is a traditional sign of failure, may in reality represent the final phase in an undefined process of circulatory adjustment, directed towards maintaining the high cardiac output necessary for the adequate functioning of the defective blood. Hunter concludes that "enlargement of the heart in anæmia, accompanied as it sometimes is by a raised venous pressure, addition of the third heart sound, and inversion of the T-wave in the right pectoral electrocardiogram, is an expression of right heart preponderance which may progress to frank heart-failure with hepatic engorgement and œdema." Here is a fascinating field for investigation. The cause of the raised venous pressure requires elucidation, and the accurate methods of assessing venous pressure and cardiac output by cardiac catheterisation, which led to Sharpey-Schafer's observations, are likely to be used sooner or later in the investigation of uncomplicated anæmias in younger patients.

PALPABLE PEDAL PULSATIONS

THE study of the normal, which has been rapidly advanced by the mass medical examinations of the late war, has provided useful data that will be of value in the early recognition of disease. The latest addition to our knowledge is the finding that of 1014 healthy American soldiers, whose average age was 20 years and of whom over 90% were under 22, there were over 13% in whom the pulsation of the dorsalis pedis or posterior tibial artery was impalpable.[1] The dorsalis pedis pulsation was absent on the right in 11·4% and on the left in 13·6%. The posterior tibial pulsation was absent on the right in 2·9% and on the left in 2·7%. In only 5 men was pulsation absent in both arteries on the same side, but in 7·5% the dorsalis pedis pulsation was absent in both feet, while in 1·7% the posterior tibial pulsation was absent in both feet.

A curious incidental observation was that the posterior tibial pulsation was more commonly absent in the Negro, while the dorsalis pedis pulsation was more often absent in the white soldier. It was confirmed that when pulsaion was absent in one artery, the other artery in the same foot had an enhanced pulsation. This observation was first recorded in 1898, by Erb[2]; but pulsation was absent in only 3 of his 381 patients. Morrison[3] found that 19% of the 1000 people he investigated had absent pulsations; but most of his subjects were women, and there was a wide variation of ages. If 13 of every 1000 healthy young men have impalpable dorsalis pedis or posterior tibial pulsations, there is clearly need for caution in drawing conclusions from the absence of such pulsations in patients with suspected peripheral vascular disease.

INTENSIVE COURSE IN PSYCHOTHERAPY

AN interesting experiment on the teaching of psychotherapy to general practitioners is reported by Mr. Geddes Smith for the Commonwealth Fund.[1] A fortnight's course for 25 doctors was held at the University of Minnesota last April in an attempt, sponsored jointly by the university and the fund, to decide whether doctors can "be taught to practise in their own offices the kind of medicine psychoneurotic patients need." The course was conducted by psychiatrists with teaching experience, including four professors and two associate professors of psychiatry, as well as two consulting psychiatrists, two social workers, and an associate professor of medicine. A group of seven neuropsychiatrists helped with the clinical teaching, and the university provided the patients. Morning lectures followed by discussions laid the theoretical groundwork of the kind of medical care the students were to learn; afternoon seminars for the whole group were designed to give instruction in method; the students undertook supervised clinical work, and discussed it at small section meetings consisting of an instructor and five students; and films and special seminars were to be arranged as requested. In practice, the lectures and section meetings proved the best teaching agents, the large group seminars being less successful. The section meetings, with their informal give and take, allowed the students to hammer out the significance of clinical work case by case. The lectures covered such subjects as general orientation, patient-physician relationship, normal personality development, the meaning of a psychoneurosis and its diagnosis, anxiety, general principles of psychotherapy, common psychopathology, combat fatigue, and the care of veterans.

The students took the course hungrily, and "were so full of the subject that they spent hours at night talking with each other and with members of the teaching staff," and they much preferred this to evening seminars or films. Many of the cases seen were of long standing—patients who had had various kinds of medical and surgical treatment elsewhere, and who are all too common in the general practitioner's surgery: "it was an excellent sample of the persistently unwell." The purpose of the interview was thoroughly impressed on the students, this being not so much to get the facts as to find out the patient's attitude to the facts and to help him to tell his own story. They were asked to listen to the patient, to let him know he had undivided attention, and to talk with him for an hour instead of the customary fifteen minutes. The transference and counter-transference were explained, students soon grasped that a positive transference at the first interview gives the patient freedom and confidence, and is a good start for treatment. The instructor usually came in just before the end of the hour and brought out factors the student had missed, or made clear the significance of what the patient had already told him. At the end of the first day one student, speaking of the anorexia of a twelve-year-old said: "Well, then, you talk her into eating." The instructor answered: "You don't talk her into it; you let her talk herself out of the reasons for not doing it."

But in psychotherapy, while principles may be easy to grasp, management of cases can only be learnt by years of training and experience; in the second week the students had to be given some understanding of the possibilities and limitations of psychotherapy—to be shown, in fact, when to go forward with a case and when to leave it alone or seek help elsewhere. Moreover, they had to learn that they themselves were influenced by patients in ways of which they were not fully conscious; and that there were many cases in which they must be satisfied to help the patient to adjust himself to irreversible handicaps, without attempting to cure him. "The patient is a person needing help; the function of the doctor is not to play God, but to give help at any and all points where after thoughtful study he sees the way to do so. . . ."

The result, judged by written comments, was a new orientation of the students to their relationship with patients. Nearly all felt that they had gained help in their daily work. From the instructors' point of view it was clear that the present generation of general practitioners are not too old to learn the psychotherapy they have never been taught: the students at this course were both eager and quick to learn.

THE M.D.U.

IN an annual report of pre-war dimensions the Medical Defence Union gives an account of careful work on behalf not only of its members but of the public. In his presidential address at the annual meeting on Sept. 24, Mr. St. J. D. Buxton, F.R.C.S., reminded members that a joint coördinating committee, made up of representatives of the M.D.U., the London and Counties Medical Protection Society, and the Medical and Dental Defence Union of Scotland has been set up during the year to develop a common policy in matters of mutual interest. On the request of the M.D.U., the British Standards Institution set up a committee (on which the union was represented) to report on methods of preventing avoidable accidents associated with the use of gaseous anæsthetics. This committee have now reported, submitting a "Code of Practice" which should in time do away with all errors due to wrongly coupled leads, and misidentification of cylinders. Copies of this report will soon be available to any member who asks for it.

In answer to many inquiries from demobilised doctors about reinstatement, the union point out that the Act of 1944 provides that an employer must take a doctor back into his pre-war post if he applies for it within four weeks of demobilisation, and "if re-engagement is reasonable and practicable." This second requirement allows of shuffling, and the deliberate evasion of responsibility; moreover, if the post was honorary or only carried a token payment it does not come within the scope of the Act. Some governing bodies of voluntary hospitals have refused to reinstate returning specialists and consultants, on the grounds that they have now given the appointments to others. This attitude, though contrary to the spirit of the Act, unfortunately cannot be attacked on legal grounds. Doctors who held posts in municipal hospitals before the war have not encountered the same difficulty, partly because their appointments were paid and partly because the Act applies to municipal staff as a whole, as local authorities fully appreciate.

During the year the union has successfully prosecuted some unqualified practitioners who have used the titles of "physician," "surgeon," or "doctor" (usually preceded by some descriptive adjective), to which they have no claim. Members who know of unregistered

practitioners contravening the Act in this way are asked to inform the union.

Some of the cases dealt with during the year included questions of fees, *certification*, and *alleged negligence*. The report again impresses on doctors the importance of care in the coupling of anæsthetic cylinders, and the dangers of explosions in the theatre; and on surgeons the need for capable swab-counting, the importance of *X-ray examination of bony injuries*, and the duty which lies on them to establish the diagnosis to their own satisfaction: it is not wise to accept a colleague's opinion and to operate without confirming his findings. One member had found a commercial firm using a quotation from an article of his, published in the medical press, to support their advertisement for a certain form of electrical treatment. Permission to use his name had not been asked. The union protested to the advertisers who withdrew all the remaining pamphlets containing the advertisement and undertook to issue no more of the kind. Other examples of the union's work could be given, for the annual report makes instructive reading; but as Mr. Buxton pointed out, the existence of the M.D.U., telegraphic address "Damocles," should suffice to remind us that the path of the practitioner may be far from easy.

THE MAKINGS OF A MEDICAL SCHOOL

IN the hope that his findings might guide them in establishing a university medical school, the governors of the University of British Columbia asked Dr. C. E. Dolman, their professor of bacteriology and preventive medicine, to make a survey of medical education in Canada and the United States.[1]

Professor Dolman visited the 11 medical schools of Canada, and 22 leading medical schools in the U.S.A., talking with heads of departments, staff members, students, university presidents, deans, representatives of the Rockefeller Foundation, hospital directors, and any others who came his way. His list of requirements for a first-class medical school begins with a stable and flourishing parent university, a large body of good applicants from whom students can be selected, enough money, and a picked staff, of whom the heads of departments and some others are to be full-time. Teaching affiliations with local hospitals, he considers, should be made on terms *satisfactory to the university*; but there must also be a university hospital staffed entirely by the faculty of medicine. The school should be placed in the campus so that the students share the life and interests of their fellows working in other faculties; and the medical faculty must share its resources with the university, offering special courses to non-medical graduates, training students for medical ancillary services, and being fully responsible for a well-developed university health service.

He found, he says, plenty of evidence that a second-class university cannot hope to have better than a second-class medical school. Though fees for the medical course are nearly twice as high as for other courses given in the same university, they seldom meet more than a third, or in some schools a sixth, of the cost, and no university should contemplate founding this expensive form of school unless it has proper resources. Too big a teaching load on staff puts an end to the serious and sustained research which must be among the first duties of a medical school. A good staff, once appointed, must *have proper apparatus for research, and such equipment* quickly goes out of date: "hence no medical school ever seems to find its budget adequate." In the United States he found that the annual cost per student ranged from $600 to $3893; and he had no doubt that the student in the expensive schools got better teaching. Tutorials and seminars are better vehicles for teaching than didactic lectures, but are possible only when the ratio of instructors to students is high; and the atmosphere is more favourable to learning in a school where *research is an honoured activity*, not an intermittent and clandestine indulgence.

The best annual entry, Professor Dolman thinks, is round about 50 students a year. The Goodenough report, it will be remembered, suggested an entry of 100, which he would *consider* too high on the ground that if a class is much over 55 or 60 it has to be split into sections, and a disproportionate number of additional teachers must be provided. Good staff are as scarce in America as here. He notes that in the U.S.A. at least four chairs, and numerous assistant professorships, of anatomy are vacant, and that good pharmacologists are even harder to find than anatomists. Medically qualified men who go in *for full-time* teaching do it at a financial sacrifice, but even so he believes that "without plenty of money one cannot hope to get good men." He is also clear that it is not enough to appoint a single full-time man in a clinical department and leave him dependent for help on part-time workers and volunteers: the result of that is to push the head of the department *into "the rôle* of chore-boy."

In discussing the medical curriculum, Professor Dolman insists that preventive medicine must be better taught, but not to the point of displacing the doctor's traditional concern with the care of the sick. He notes the increasing popularity of joint conferences in which the anatomist, bacteriologist, biochemist, and pharmacologist take equal part with the physician and surgeon. In some of the best schools the department of psychiatry arrange lectures, demonstrations, and seminars, on normal psychology and on the psychological bases of abnormal behaviour, for students in their first and second years. The various departments must be closely interrelated not only in the intellectual but in the physical sense it is hard to coöperate fully over a gap of, say, six mile He believes that every link possible should be forge between the medical school and the general practitione as well as with State health departments. Perhaps hi *most telling observation is that*—"the form and fame a medical school is very largely determined by th character and ability of its first Dean."

MEDICAL RESEARCH COUNCIL

THE Committee of Privy Council for Medical Researc have appointed Group-Captain C. A. B. Wilcock, M.P Dr. C. A. Lovatt Evans, F.R.S. (professor of physiolog in the University of London), and Dr. R. A. Peters, F.R (professor of biochemistry in the University of Oxford to be members of the Medical Research Council.

RETIREMENT OF MR. F. W. MARTIN

WE who produce this journal have lost a value colleague by the rétirement on Sept. 26 of Mr. Marti our head printer. He and his father, W. G. Marti between them held this office for 56 years, and his father' association with THE LANCET began over 70 years ag On July 4, 1893, Frederick William Martin was boun apprentice for seven years to Thomas Henry Wakle F.R.C.S., and Thomas Wakley, jun., L.R.C.P., then pr prietors of THE LANCET, to learn "the Art of Lette Press Printing, which they use"; and until 1921 h worked at 423, Strand, where the typesetting was don above the editorial office. When 25 years ago the print ing was transferred to Messrs. Hazell, Watson, an Viney, in Long Acre, Mr. Martin joined their staff bu continued his close association with the editorial an managerial departments of the journal. Among us h had by far the longest experience of THE LANCET, an he did much to preserve its standards and transmit it tradition. The apprentice became himself a teache and counsellor, and remains a f

CHILDREN IN DAY NURSERIES

WITH SPECIAL REFERENCE TO THE CHILD UNDER TWO YEARS OLD

HILDA F. MENZIES
M.D. Aberd., D.P.H.
DEPUTY MEDICAL OFFICER OF HEALTH, LEYTON

DURING the war there was a mushroom growth of nursery accommodation for children under five years of age. The Ministry of Labour and National Service pressed local authorities to establish nurseries as a means of encouraging mothers of young children to do full-time industrial work. Whether it was really wise to give mothers of young children this encouragement may be doubted (Menzies 1944).

By January, 1945, up to 1500 nurseries had been established with a maximum of 50 children per nursery. Since then about 200 have been closed. The latest estimates of the Ministry of Labour (as quoted in the *Times* of June 20, 1946) show that in the first ten months of peace nearly a million women left industry to return to their homes, and the number actually engaged in civil employment in April, 1946, was 5,420,000. The proportion of women therefore whose children were in nurseries during the war represented rather over 1% of the total number of women in industry, and as a result of closing 200 nurseries a maximum of 10,000 women may have left industry—again 1% of the total who ceased work. This disposes of the argument that the establishment of nurseries has had any appreciable effect on the labour situation.

The statement recently made in a propaganda leaflet, that the ability of women to remain in or re-enter industry "will depend largely on the speedy setting up of more nurseries and nursery schools," oversteps the bounds of justifiable emphasis which one expects to find in propaganda. A more reasonable argument is that nurseries have a contribution to make towards maternal and child welfare; but here again we should look at the facts in correct perspective against the background of general maternity and child-welfare services. The proportion of children under five years of age who were in nurseries during the war was only 2–3%; so the health of young children in general will not so far have been appreciably influenced by nursery provision.

The few nurseries in existence before the war were established for social reasons—to care for children whose mothers had to earn their living, or for those whose home circumstances were unsatisfactory. Curiously enough, there does not seem to be any published record of the progress of these children.

It is perhaps less surprising that the progress of children in war-time nurseries has not been recorded *; for the establishment and supervision of nurseries fell on depleted public-health staffs who had often Civil Defence duties besides their usual work. It seems important, however, that the progress of these children should be watched carefully, particularly if in the future there is to be any extension of nursery provision to make things easier for the tired mother.

Most mothers probably find their young children a trial at times, and those who have to care for one or more young children and run a house unaided have a tiring time; but how many of them will be prepared to secure their own relief unless they can be assured that their children will do equally well away from them? This factor operated even during the war, when there was a good deal of propaganda to induce mothers to go to work. In Leyton—which was not an area with much employment of married women before the war, and has a good standard of maternal care—when we set up two nurseries, for 50 children each, we had 48 withdrawals within one week, and another 36 within four weeks of admission. The majority who left within this time were considered by their mothers to be "fretting." Have we enough knowledge of the development of young children to tell these mothers they were wrong?

Since I have had an opportunity of examining the records of those children admitted before they were two years old who remained in the nurseries over three months, I think it is possible that those mothers who withdrew their children made a wise decision.

The rapid turnover of children in the nurseries is very striking; and, if experience in other nurseries has been similar, this may have been one reason which deterred medical officers from recording the progress of children. It also suggests that the nursery population is selected: the children of whom we have records are those who have stayed the course. In theory one would have expected that with certain exceptions—e.g., children withdrawn because of the mother's pregnancy—a child admitted to a war-time nursery would have remained there until he went to school. Yet in three and a half years in Leyton 368 children (occupying 100 nursery places) have been admitted and left, and of these only 60 (16%) have stayed until they went to school; 54 left within a week of admission, another 47 within a month, and 222 within six months. The obvious retort of the enthusiast will be that the fault is in the individual nurseries, and this may be suggested when my figures of progress of children under two years are read. But I shall be content if the critics record their own experience for comparison. From the remarks of the numerous visitors (official and otherwise) whom nurseries attract, the nurseries in Leyton seem to have been as good as the average, and a good deal better than many. The last inspector we had observed that as soon as she entered the door she could tell that the atmosphere of the nursery was good.

PROGRESS OF CHILDREN UNDER TWO YEARS OLD

Gain in weight is the most obvious tangible evidence of progress in the young child.

I have so far only tabulated the progress of children who were admitted to a nursery before they reached the age of two. This appears to be the most important group to study in the first place, because these children are not yet old enough to benefit from association with other children, and there are certain obvious risks—namely, fretting through separation from the mother, and infections.

GAINS IN WEIGHT

Age on admission (months)	Nursery	In 3 months		3–6 months		0–12 months	
		No. of children	Av. gain (lb.)	No. of children	Av. gain (lb.)	No. of children	Av. gain (lb.)
12–18	A	26	1·00	20	1·17	9	5·30
	B	32	1·40	24	1·34	16	5·12
18–24	A	15	1·49	10	1·08	3	4·29
	B	27	0·96	20	1·38	11	5·00

Of those admitted under two years old 76 left within three months, and it is therefore impossible to make any record of them.

In children under a year old the gain in weight is very definitely related to the month of life. The numbers in the nurseries at this age were not large enough to subdivide them; but, of 32 children who were admitted in their first year and stayed more than three months, 8 gained 0–8 oz. in weight in the first three months in the nursery, and another 7 gained 8–16 oz. An average gain of a child at this age, putting it at a low estimate, is 1 lb. a month.

---

* Since this paper was written a report on the health of children in war-time day nurseries has been published in the *British Medical Journal*, August 17, p. 217.

The accompanying table shows the gain in weight in the first three months, in the second three months, and in the first twelve months of two groups in each nursery —those admitted when they were between twelve and eighteen months old, and those admitted when they were between eighteen months and two years old. Besides the average gain in weight in each group over the period stated, I have indicated the number of children in each group on which the gain in weight is calculated. It is obvious that the number who remained in the nurseries for a year or longer are a selected group, and the number in each age-group is too small to justify any definite conclusions. The average gain in weight of children between one and two years old may be considered to be 5–7 lb.; hence these gains appear to be at the lower limit of normality.

To take the average gain conceals the progress of individual children; but, of 58 children admitted at ages between twelve and eighteen months, 3 lost weight in the first three months, 9 gained 0–8 oz., and a further 9 gained less than 1 lb. Thus over a third made unsatisfactory progress in the first three months. In the second three months 2 children lost weight, 5 gained 0–8 oz., and 4 gained less than 1 lb. The total number of children here was 44; so a quarter made unsatisfactory progress in the second three months.

Of 42 children admitted aged between eighteen months and two years, 7 lost weight, 3 gained 0–8 oz., and 5 gained less than 1 lb. in their first three months in the nursery—i.e., in a third the gain was unsatisfactory. In the second three months out of 30 children 2 lost weight, 6 gained 0–8 oz., and 3 gained less than 1 lb.

As children in nurseries are in a favoured position as regards rations, compared with children whose mothers are looking after them at home, I regard the progress of these groups of children admitted under the age of two years as disappointing. It is reasonable to suppose that illnesses explained the poor gains to some extent, but this cannot be the whole explanation, because some children had as many as four infections and progressed satisfactorily, whereas others had no illness and yet did badly. Nor does it seem possible to foretell which child will do reasonably well and which will do badly. The fact that a child has had poor maternal care does not necessarily lead to its doing well when admitted to a nursery. Thus in a child aged between eighteen months and two years, with the note "care poor, verminous, went to residential nursery," there was a loss of weight of 15 oz. in the first three months in the nursery, and a gain of 15 oz. in the second three months. In that time the only illness was German measles. Another child, who was a removal into the district and whose mother appeared to have a low standard of care, gained 11 oz. in the first three months and lost 3 oz. in the second three months, again without having anything more serious than German measles. Of all our admissions we had only 1 child with chronic malnutrition from lack of food, and this child did well, gaining 3 lb. 12 oz. in the first three months, and 3 lb. 3 oz. in the second three months. Children whose general nutrition on admission was poor from no obvious cause did nothing spectacular.

In February, 1943, a warning was issued from the Ministry of Health to medical officers that nutrition in nurseries, particularly of children between one and two years of age, was in some areas less good than it should be. This was considered disturbing in view of the fact that nursery children got extra rations. It was evidently assumed that this poor nutrition in nursery children was due to some lack in nursery dietaries, for medical officers were advised to review the dietaries of the children, and extra iron was made available.

From the time the nurseries opened in Leyton in August, 1942, I had gone over the menus very carefully with the matrons. We had insisted on every child having cod-liver oil and fruit juice daily, and I had ordered a preparation of iron for those children who seemed to need it. I am not therefore prepared to agree that failure to gain weight adequately in the cases I have listed is due to anything so simple as lack of proper food. It seems more likely that it is due to emotional disturbance, and if this is so it is much more serious.

It is not unusual for a young child to take anything from a week to a month to settle. This period of adjustment *to unknown people and surroundings* may be characterised by continuous or intermittent crying, refusal to eat, refusal to sleep, or refusal to sit on a chamber without screaming. It is an unhappy time for all concerned.

Susan Isaacs (1932) mentions that emotional causes may affect weight gains in young children. Freud and Burlingham (1943), who made a detailed study of children in residential nurseries, found that in children from one to two years old the motor control was better in nurseries than in homes where freedom to move was restricted, but that the nursery child "is at a disadvantage wherever the emotional tie to the mother or to the family is the mainspring of development. Comparisons between children under these contrasting conditions serve to show that certain achievements such as speech and habit training are closely related to the child's emotions, even though this may not be apparent at first glance."

It is recognised now that too early and too strict habit-training in babies may lead to a relapse later on. Bowley (1942) says that bowel control should not be expected before the age of twenty-one months, and bladder control before that of twenty-four months. In our child-welfare clinics we advise the mothers on these lines and warn them of the dangers of overinsistence on cleanliness, but in nurseries it is inevitable that strenuous attempts at habit training should be made with the under-twos. "Potting time" is recognised in the nurseries as a time for squalls. The dangers of gastro-enteritis in young children have been brought back to us in recent years with the rise in the death-rate from gastro-enteritis in children under two years old, and this more obvious risk is bound to determine procedure in nurseries.

The social development of the child is tied up with his emotional development. So if this failure to gain weight adequately is evidence of an emotional hold up, the effect may be far-reaching.

INFECTIONS

At one nursery 54 children out of a total of 72 (admitted under the age of two years) who remained longer than three months in the nursery developed one or more infections. At the second nursery the proportion was 35 out of 60. The commonest infections were of the catarrhal type—measles, whooping-cough, German measles, bronchitis, and pneumonia, but scarlet fever mumps, dysentery, jaundice, and chickenpox all occurred. Some children had as many as *four* infections, and of 60 children (including the admissions under the age of twelve months) who remained twelve months or more in the nurseries, only 7 escaped infection. I counted acute bronchitis only if it led to several weeks' absence from the nursery.

A preliminary study of infections in war-time day nurseries was made in Oxford from the Institute of Social Medicine (Allen-Williams 1945), and from the records analysed it appeared that children attending day nurseries were more liable to contract infections than were children living at home, and the infections occurred at an earlier age in the day-nursery population. The investigator discussed the likelihood of the infection-ates being underestimated in both sets of records, and ssumed that the nursery records would be more complete s the children were under daily skilled supervision. That might be a safe assumption so far as the Oxford ecords were concerned, but anyone who remembers he conditions in London war-time nurseries will agree hat the matrons there had every excuse for not recording on the children's cards all their absences through illness. There was usually a shortage of staff, and, particularly from June, 1944, the children were in and out of air-raid shelters all day long. Careful recording was the last thing one could expect under such conditions.

EXPRESSIONS OF OPINION

Kershaw (1946) criticised the Oxford survey as being at the same time too scientific and not scientific enough, and in his criticism he betrayed a bias in favour of nursery provision, but he did not provide any facts to back his opinions. In his own words "We have tended to rely too much on general impressions often coloured by preconceived ideas."

Other expressions of opinion have been made recently.

> "The scope of the evidence is admittedly limited, but so far as it goes it does not indicate a beneficial effect of nursery life for the younger children—rather the reverse. There was a general increase of respiratory infection, to a significant extent in some instances, but no constant or significant improvement in physical development as indicated by weight or the doctor's impression of general physique" (Medical Women's Federation 1946, in a report based on the records of 4587 children in 22 local-government areas).

> "The advantages of a day nursery or nursery school are much greater (than a home help) for the child. A child needs training and discipline from the very beginning of its life, and this training can only be suitably given when there are facilities for mixing with other children. . . The children are taught regular habits, are given well-balanced meals adequate in quantity and quality, and have proper periods of rest and sleep as well as of activity" (Paul 1946).

> "The danger of infection was there but was just a thing to be overcome. Good nutrition was one safeguard. The social benefit of mixing of children was great and he doubted if the family was always the best place for their bringing up" (Roberts 1946).

> "Day and residential nurseries have contributed a good deal to the improved knowledge and actual nutritional standard of children" (*Nutrition and Child Welfare* 1946).

I shall look forward to reading the investigations which would justify such opinions. I am not in a position to make any such definite statement, but as the result of studying the progress of children under two years old, admitted over a period of three and a half years to two war-time day nurseries in London, have come to certain conclusions.

CONCLUSIONS

Of children under two years old a substantial proportion do not make satisfactory progress on admission to a day nursery, as judged by their weight gains in three-monthly periods. This is in spite of the fact that over the period under review children in nurseries had available what amounted to almost double rations compared with children whose mothers cared for them at home, and that a very careful attempt was made to satisfy the dietary requirements of young children in the nurseries I have been supervising.

It is recognised by psychologists that emotional disturbance interferes with weight gains in young children; and, as it is obvious from their behaviour that these children do suffer an emotional upset on admission to a nursery, this may explain their failure to gain weight adequately. It is not necessarily possible to tell from their subsequent behaviour whether they are making satisfactory gains in weight.

Most of the children admitted under two years old who stayed in the nurseries developed one or more [illegible] tions sooner or later. The extent of the infection-rate is less obvious owing to the practice of accepting on the register about 20% more children than there are places available in the nursery, but a recent epidemic of measles in one nursery reduced the attendance to 14.

In considering what proportion of children in these ages do or do not make satisfactory progress, and do or do not develop infections, account must be taken of the number who leave either because their mothers consider they are fretting, or because they contracted an infection from the nursery. There is a tendency to forget about them. The mother does not attend mass meetings to describe the effect of the nursery on her child. She simply removes the child.

We require guidance from those best qualified to judge what is the earliest age at which a normal child may be removed from his mother, home, and familiar surroundings, and for how many hours a day, without the likelihood of experiencing emotional upset. As a corollary to this, at what age does the young child begin to benefit from mixing with other children?

The opinions expressed here are personal and are not intended to represent those of the borough of Leyton.

INTERNATIONAL MEDICAL CONFERENCE IN LONDON

A CONFERENCE at which 21 European countries and 10 countries outside Europe were represented was held at the British Medical Association House in London on Sept. 25–27. The meeting was under the joint auspices of the Association Professionelle Internationale des Médecins and the British Medical Association, whose president, Sir Hugh Lett, was in the chair. Most of the national medical associations were represented by two delegates, and some of them by observers also; the American Medical Association was represented only by observers. Delegates from both the Palestine Arab and the Palestine Jewish Medical Associations were present.

Sir HUGH LETT, in welcoming the delegates, mentioned the interest of the B.M.A. in international coöperation, as testified by its recent allocation of money for sending medical lecturers to the Continent, and also by the forthcoming establishment of an abstracting service to cover all medical literature.

OBJECTS AND FUNCTIONS

On the motion of Dr. ALFRED COX (B.M.A.), seconded by Dr. P. MORAN (Irish Free State Medical Union), and supported by the Polish, Spanish, and Swedish delegates it was unanimously agreed that an international organis tion of medical associations should be set up. A lo discussion on the objects of such a body centred larg on whether these should be limited to matters of med practice and social medicine or extended to scier coöperation. The Polish delegates wanted scie medicine included, but this was resisted by the Fr Belgian, Greek, and Dutch delegates, who point that every country had its academies, and th immediate need was for an organisation to def rights of the ordinary practitioner, especially of legislation passed or pending in many [illegible] (Canada) suggested body might serve as the medical counterpart to the World Health Organisation recently established in New York. Without the help of the medical profession in the different countries, he said, the W.H.O. would be like an electric grid without power; no national governments could do anything with this new instrument unless the doctors in every country made it alive. What he desired was a world medical organisation to signify the unity of the world's doctors, knowing no geographical boundaries and concerned only to help mankind to attain the highest possible level of health.

A whole morning was spent in considering various formulas to express the objects of the world association. Ultimately the following was agreed to:

> "To promote closer ties among the national medical organisations and among the doctors of the world by personal contact and all other means available in order to assist all peoples of the world to attain the highest possible level of health; to study the professional problems which confront the profession; to organise an exchange of information on matters of interest to the profession; and to establish relations with, and to present the views of the medical profession to, the World Health Organisation and the United Nations Educational, Scientific, and Cultural Organisation."

The last phrase was arrived at after the rejection of a number of alternatives. Dr. P. CIBRIE (France) declared that in his country there was some suspicion of the W.H.O. and of UNESCO. Should these bodies assume bureaucratic functions, any agreement to coöperate with them would prove embarrassing. Dr. F. DECOURT, secretary of the A.P.I.M., spoke to the same effect. One of the reasons for the establishment of a world medical organisation, he said, was to defend medical practitioners' liberty, now menaced in several countries; to proclaim in advance that they were prepared to coöperate with these new official organisations would be unwise.

Dr. G. B. CHISHOLM, as an observer representing the World Health Organisation, said that under the W.H.O.'s constitution there would be no interference with the practice of medicine in any country. He quite understood the concern at possible regimentation of the profession; the interim commission which was now engaged in framing the constitution of the organisation was well aware of that concern. There would be no attempt to control the practice of medicine. On the contrary, the new organisation desired the advice of bodies which could speak for the medical profession; and it was ready to do all it could towards improving the health of the people.

NAME AND CONSTITUTION

Several delegates wished the name of the old body, the A.P.I.M., to be retained, but an amendment to this effect was defeated by 22 votes to 14. The suggestion that the name should be "World Federation of Medical Associations" was opposed by some countries, owing to the implications of the word "federation." Ultimately, on the proposal of Dr. I. C. MICHAELSON (Palestine Jewish Medical Association), seconded by Dr. J. A. PRIDHAM (B.M.A.), the title "World Medical Association" was agreed to.

It was also agreed that the members of the World Medical Association should be national medical associations. It was pointed out that in some countries more than one medical body could claim that rôle. Dr. CIBRIE, who said that in France there was only one representative body, the Confédération des Syndicats Médicaux Français, suggested that the criterion for admission might be that the membership must include half or more of the country's practising doctors.

It was agreed that the medical associations represented by delegates or observers at the conference should be eligible for membership, together with an[illegible]al or territorial medical association which was representative of the medical profession in its country or territory.

The subscription was fixed at half the rate for the A.P.I.M., the reduction being made in view of the straitened circumstances of several countries. Accordingly, the subscription will be 10 Swiss centimes per member of each national group, up to a total of 10,000 members; and 5 centimes per member above the first 10,000, with a maximum of 1500 Swiss francs.

It was also agreed, subject to consideration by the provisional committee which was to be set up, that each member-association should have two seats on the governing body or conference, and that voting should be by countries. This implies one country one vote, with exceptions, such as Palestine, where there are two medical associations representing different races.

A claim was made on behalf of the British Medical Students Association, which was represented by observers, that the medical faculty-group of the International Union of Students should be admitted a member. This was opposed by the French and Belgian delegates, but the conference agreed to recommend to the committee that the two representatives should be admitted, but without voting power.

COMMITTEE AND SECRETARIAT

It was agreed to set up a provisional committee of nine, and to entrust to it the task of putting into French and English—the two official languages of the new body—a draft constitution and bylaws embodying the recommendations made by the conference. This will be submitted to the next conference, the first meeting of the World Medical Association, which, it was recommended, should be held in Paris, on a date to be decided by the committee.

The following were elected, by ballot, members of the committee:

Dr. F. Decourt (France), Dr. P. Glorieux (Belgium), Dr. Dag Knutson (Sweden), Dr. O. Leuch (Switzerland), Dr. J. A. Pridham (Great Britain), Dr. T. C. Routley (Canada), Prof. I. Shawki Bey (Egypt), Dr. L. Tornel (Spain), and Dr. A. Zahor (Czechoslovakia).

It was further agreed that there should be a dual secretariat, one secretary to be in London and the other in Paris. Dr. Charles Hill (secretary of the B.M.A.) and Dr. Cibrie were appointed to act in these capacities until the next conference.

Regarding the future programme, Dr. MICHAELSON suggested that the committee should obtain information as to the number of refugee doctors who are still not absorbed, and determine a general absorption rate sufficient to give employment to all refugees. The new association might act as a clearing-house for the resettlement of refugee doctors.

At the close of the conference, Sir HUGH LETT, replying to a vote of thanks, said that it had been a great privilege to preside. If only international coöperation could be secured between the medical men of different countries a big step would have been taken towards permanent peace. He wished to acknowledge the public spirit shown by Dr. Decourt and others in sustaining the old A.P.I.M. through difficult years and consenting to the new organisation taking the place of the old.

GOVERNMENT LUNCHEON

The delegates and observers were entertained by the Government to luncheon at the Dorchester Hotel, Mr. Aneurin Bevan, the Minister of Health, presiding. Mr. BEVAN expressed his appreciation of the initiative and imagination of the British Medical Association in summoning the conference. "There is no more important contribution that citizens can make towards universal appeasement than to meet each other as fellow craftsmen d as members of the same profession." When politi- ns got together, friction of various kinds was likely arise, but doctors in their assemblies "are not primarily ncerned about who is going to do a thing, but that the ing is going to be done." It did not matter to the ctor whether the patient were black or white, brown yellow, Communist or Fascist. "There is in medicine catholic interest and dedication to the welfare of ankind, a concern for the individual, quite indepen- ently of his social group, his inheritance, origin, or estination. It is therefore of supreme importance that ie organisation which has been born today should ave a successful inauguration and be continually istained by the enthusiasm of its founders and those ho come after them." Dr. J. A. PRIDHAM and Dr. P. LORIEUX replied.

The council of the British Medical Association also ave a dinner at which the presidents of the three Royal olleges were present. On the last afternoon of their tay the delegates, at the invitation of Sir Alfred Webb- ohnson, paid a visit to Middlesex Hospital.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS

MR. BEVAN'S LETTER ON MATERNITY SERVICES

AT a dinner held in London on Sept. 27 Lord WOOLTON, proposing The College, spoke of the distinction between being governed by public opinion—by the trust we have n one another—and being governed by edict and legis- ation. However high its own standards, the Government had perhaps something to learn in this connexion from the Royal Colleges, whose lack of specific powers made them all the more powerful. As a friend of Blair-Bell, founder of the college—"a great dynamic force constantly searching out new things"—Lord Woolton was glad to see that the dream had come true.

Recalling how, many years ago, he and his wife started one of the first maternity clinics, and the first antenatal clinic, in the North of England, Lord Woolton said that when he became Minister of Food he regarded it as an opportunity to do something to raise the standard of maternal and infant life, and in this he had been fortunate in having the help of Lord Horder and Sir Jack Drummond. By directing cod-liver oil, orange juice, and other supplements to pregnant and nursing mothers "I think we did something." No Minister could go ahead of the general sense of the public without being called an idealist, but as soon as he declared his policy of putting children first, Lord Woolton had ceased to get abusive letters about rationing: "the public thought I was right." There could be no wiser expenditure of public money than on preserving child life.

Mr. EARDLEY HOLLAND, responding as president, said that the college had grown rapidly in its 17 years and was hoping soon to receive a royal charter. Two-fifths of its existence had been in the difficult years of war, in which its members, unlike physicians and surgeons, had usually had to turn to different tasks. But the membership, which before the war was 580, was now 775. No less than a quarter of the fellows and a third of the members lived and worked in the Dominions, and the college was very proud of its Dominion fellows, many of whose departments were second to none in this country, and wanted them to have more part in its work. It was to hold an examination in Australia next year, and Sir William Fletcher Shaw, his predecessor as president, was even now on his way to Australia to make arrangements. Being still young, the college had still to work its way to fame by the quality of its work, and among the many subjects being discussed by its committees were population problems, human fertility, analgesia in childbirth, neonatal mortality, maternity hospitals, and the social and economic aspects of the maternity service. For the Royal Commission on Population it had undertaken a questionary of considerable difficulty, and in 1944 it had issued a memorandum on a National Maternity Service which already seemed to have influenced the planning of a service and the Government's Bill.

During the last few years, Mr. Holland continued, there had been a great change of outlook on obstetric practice. The "new obstetrics" must be practised on a broad national basis and was concerned with the social and economic factors. Obstetrics had, moreover, become a form of "precision practice" very different from the old. With blood-grouping, tests for rhesus factor, and radiological examination becoming matters of routine, and with new techniques against infection and shock, obstetrics had been completely transformed in the last ten years. As the techniques became more precise the standards of accomplishment must be raised among all who did midwifery—whether midwives, general practitioners, or specialists. This year the council had decided to double the period of training required of candidates for membership. While the college believed that the general practitioner should play a most important part in the maternity service, it maintained that only practitioners with postgraduate training or special experience should be considered capable of going to the aid of the midwife in difficulties.

The National Health Service Bill would become law in a very short time, after which "we shall have to get round a sort of peace conference table, but with more hope in our hearts than in Paris." In April, 1948, he felt sure, "we shall, like loyal citizens, carry out the will of the people and do our best to make the finest maternity service in the world." In time it should be possible to secure throughout the country an even distribution of those techniques now waiting to be used. The college's memorandum had laid emphasis on coördination between the various bodies which under the Bill would be responsible for the maternity service. The Minister had said that perfect coördination could be assured by administrative action, and in answer to a request for fuller information had sent him a letter which said:

> We have always envisaged that in staffing their antenatal clinics local authorities must enlist the coöperation of the regional board, and that this will be done by appointing one of the hospital obstetricians as officer in charge of each of the local antenatal clinics. This would enable the obstetrician to determine whether the mother will ultimately require admission to hospital (and to take the necessary steps accordingly) or whether she can be left to the care of the midwife, with the facilities of the hospital or the services of an obstetrician or experienced general practitioner always available in the background. This arrangement would ensure also that the social services of the local authority in the shape of the health visitors would be at the disposal of the obstetrician in the clinic, and similar service will of course be at his disposal by arrangement with the local authority in the hospital. But above all *we must* remember that the general practitioner is one of the chief coördinators of the service. He is the manager who produces for the benefit of his patient all the facilities which the National Health Service can offer. He will have contacts with all the working parties of the machine—the hospital, the clinic, the health centre, and the services of the local authority—and will personally know the men and women who staff them.
>
> We have *still* a good deal to do in planning out the precise details of the organisation, but these are the main lines along which it will be developed.

Royal colleges, said the president in conclusion, set the standards of specialist practice and therefore of all practice. "The college spirit in medicine is precious, is unique, and is peculiarly British, and its flame must never die down"; but the colleges must continue to make progress: their power and prestige now depended not on privileges but on cultural and even spiritual qualities. "Many of us believe that instead of working in complete isolation, like independent sovereign States, the colleges will come to work more and more closely together," and it was essential that they should achieve unity and harmony. It was essential too—though the day might be far distant—that they should come together geographically. His own college would in any case soon be forced to move house because in more ways than one it had grown out of the premises given it by its founder.

Mr. A. A. GEMMELL proposed The Guests, whom he included in the definition of the college as "a fraternity with a common purpose." Among those he mentioned was

Mr. Victor Bonney, admitted to the fellowship earlier in the day. Without going so far as to apply the parable of the lost sheep, Mr. Gemmell admitted that "there is more joy in our ranks because he has joined us than there would be over any other man."

Sir HUGH LETT, president of the British Medical Association, in reply, said that today no-one would be bold enough to put the question "is your college really necessary?" Before the college was founded the situation of surgery, medicine, and obstetrics recalled the old-fashioned bicycle in which there were two big wheels and a little one which ran behind without anybody noticing. In the last few years obstetrics and gynæcology had advanced so rapidly that it was essential to have a body like the college not only to lead developments but to speak with authority. Medicine was not only a great profession; it was the ideal profession: no other calling offered such opportunities for development and pursuit of the finest ideals. The ideals often met with disappointment in practice, but it had been well said that the joy of an ideal lies in its pursuit.

After touching on the risk of dividing medicine into specialties, which might lead the doctor to overlook the whole of the patient, Sir Hugh spoke of the danger that people in certain departments of medicine should regard themselves as the profession. It was of the greatest importance at this time that the profession should feel itself united and express its voice in such a way as to impress those in authority. Unity must be secured between the colleges themselves and between the colleges and other professional organisations. The work of the colleges was a special academic work, for which they were particularly fitted, but other things could be done only by such a body as the British Medical Association. One could not always be sure that the "will of the people" would bring about the good of the patient. Medicine should speak with one voice on what it believed to be in the best interests of the people as well as of the profession.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE University of Edinburgh is planning a considerable extension of its premises. For many years now the accommodation in the university buildings has been wholly inadequate, and in the period after the war of 1914–18 new departments were built on the south side of the city some distance away from the old university buildings and from the medical school. As a result the university was scattered rather widely over the city with a consequent loss of corporate sense and much inconvenience to all concerned. The present plan has been prepared for the university by Dr. Holden in consultation with Sir Patrick Abercrombie and Mr. Plumstead, the town planning officer for Edinburgh. Principal Sir John Fraser publicly described the plans some weeks ago and emphasised the urgency of beginning to put them into effect. The Edinburgh town council has now expressed its general approval, at least in principle, of the first stage of the development, and Sir John Falconer, the lord provost, has given the scheme for the formation of a university precinct his blessing.

It is intended that almost the whole area between the present old university buildings in the South Bridge at one end, and George Square and the Meadows at the other, should become a university area without interfering with the principal traffic routes which pass through this part of the city. The plan foresees the construction of teaching buildings on all sides of George Square with university hostel accommodation in Buccleuch Place and its neighbourhood. It is intended to develop the medical school by extending its buildings from the present New Quadrangle in Teviot Place backwards to include the north side of George Square. This will mean a great increase in accommodation for the various departments of the medical school. It is understood that the new building programme will not involve the abandonment of the buildings at West Mains Road, which are mainly occupied by departments of the faculty of science, but the arts and other faculties still accommodated in the old university buildings in South Bridge have been in a hopelessly cramped situation, and the provision of additional and better premises for these faculties is an urgent matter.

Public Health

Prospects in Industrial Medicine

A CONFERENCE held at Leeds last summer[1] reviewed the difficulty of giving medical care to people working in small factories—some 53% of the whole industrial population. Accidents and disease are commoner in these small factories, as Dr. C. G. Kirkland pointed out. He suggested that a mobile corps might be formed for factories, to take the doctor to the job. Dr. J. Vaughan Jones thought the care of people in these smaller factories could not be left to voluntary effort. In one or two places—at Bedford, and at Cray in Essex—small firms have grouped themselves together to provide medical care for workers, but such schemes he believes are not likely to become widespread: the interests of small firms are too diverse. He upheld the view of the Leeds joint council that industrial medicine should be a statutory service, regionally planned. The statutory principle was supported by nearly all the speakers. Many doctors felt that because they were paid by the firm they were at a disadvantage with workers, who suspected them of being "gaffer's" men, more interested in production than in the health of the producers.

Discussing the organisation of a statutory service, Dr. G. F. Keatinge said it would not do to put the responsibility of medical supervision on the existing examining surgeons, because they can only give a limited amount of time to the work; besides, their approach is personal instead of being environmental and occupational. He thought that a corps of specialists in industrial medicine should be formed, to be called occupational health officers. They would be the next link in the chain after the school medical officer, supervising conditions for the worker from his entry to industry to the end of his working life.

Many speakers noted that while the industrial medical officer can recommend alterations in working conditions, he has at present no authority to demand them. As a State servant he would be able to insist that workshops were maintained at the statutory level; though, as Dr. N. J. Cochran remarked, this might limit him, too: an intelligent doctor employed by the firm could suggest improvements beyond the statutory level.

It was generally agreed that industrial health research falls short in scope, speed, and operation.

The General Register Office

The branches of the office which were evacuated to Blackpool at the beginning of the war have now returned to Somerset House, London. The Registrar-General and a small staff remained at Somerset House throughout the war, but the general work of the office has been carried out at Blackpool. The records of births, deaths, and marriages were arranged and indexed there and then sent to Somerset House to be kept in the vaults. The whole of the office is now housed in London, except a part of the statistical branch and the whole of the Central National Registration Office which remain at Southport.

Infectious Disease in England and Wales

WEEK ENDED SEPT. 21

Notifications.—Smallpox, 0; scarlet fever, 853; whooping-cough, 1610; diphtheria, 240; paratyphoid, 17; typhoid, 13; measles (excluding rubella), 1208; pneumonia (primary or influenzal), 312; cerebrospinal fever, 30; poliomyelitis, 28; polio-encephalitis, 3; encephalitis lethargica, 1; dysentery, 60; puerperal pyrexia, 106; ophthalmia neonatorum, 69. No case of cholera, plague, or typhus was notified during the week.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (1) from an enteric fever, 1 (0) from measles, 0 (0) from whooping-cough, 3 (2) from diphtheria, 38 (3) from diarrhœa and enteritis under two years, and 5 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 266 (corresponding to a rate of 30 per thousand total births), including 41 in London.

1. Industrial Medicine. Report of Conference held in Leeds on June 20, 1946, by the Leeds Joint Council on Industrial Medicine, the Burton-on-Trent Advisory Council on Industrial Medicine, and the Derby Advisory Council on Industrial Health.

In England Now

A Running Commentary by Peripatetic Correspondents

THE "squatters" have only recently burst on astonhed newspaper readers. But the game is not new, s several hospitals can testify. One hospital urgently eeded a large house and actively tried to obtain it. But he process of purchase and derequisitioning takes an mazingly long time and the house stood empty for nonths. So the homeless understandably assumed that ince the war-time residents had long since gone, no-one vas coming in; so in they went. How to get them out s another matter, but if the "usual channels" in Whitehall had not been so long, twisting, and clogged he trouble would never have arisen.

Another hospital, warned of its friend's dilemma and being itself endowed with the experience of many centuries, bought a house, and, since on the day it was derequisitioned the keys were not forthcoming, it applied padlocks to the outside of all the doors just to make sure. Thereafter it could set applications for licences in motion in a fairly secure frame of mind, and in the hope that its bombed-out nurses might some day find a resting place. But alas, that was too easy. The applications having gone the rounds for some two months and no answer having arrived, the premises had to remain unoccupied, and a new requisition order was issued by a different authority. And so the battle for derequisitioning started all over again. Meanwhile the nurses are thinking of doing a bit of squatting on their own account.

* * *

It was balm to me, as one of that ignorant class who learn most of their nutritional theory and practice from the daily press, to read in my evening paper the suave statement that "the reduction in the extraction-rate, nevertheless, will mean that bread will have a greater nutritional value, as the 5 per cent. reduction is equivalent to that amount less bran going into the bread." And, having read it, I was immediately in an awful state of mental conflict. Did not this contradict the assurances, so smoothly proffered, that previous increases were all for the good of our health and "nutrition"? Had I not read not so long ago an opinion of one of the Highest, that the (then) darker loaf was to contain more and more of five specified things and of a sixth class "some of them possibly not yet discovered"?

Well, I took the trouble to look it up, and I *had* read it all. I now suspect that these dizzy changes in our extraction-rate are but one voice in an elaborate counterpoint, grandly interpreted by the Public Relations Officer virtuoso on an instrument composed of "our medical and scientific advisers." I was pained to find how often I had meekly made a virtue of a necessity, gobbled up temporary surpluses, and skated round less temporary shortages. Of course I do not know whether the statement which set me inquiring was, or was not, part of an official hand-out. Perhaps it came from the Opposition. I hope it did; otherwise I could only say to the official spokesmen "Bah! Eat your words—they're so nutritious."

* * *

This complex modern life has given rise to an ever-increasing number of occupational diseases, and the participants in such a characteristically civilised activity as a world war have added their quota of martyrs to the inventive genius of mankind. For example, that vehicle of death, the jeep, has so often traumatised the posteriors of its hardy occupants and caused inflammation to arise in previously unsuspected pilonidal sinuses that the American Army Medical Corps has dubbed this complaint jeep disease.

But places and circumstances as well as machines have their own particular hazards. I well remember a winter spent in a much-bombed Italian market town, where there was, for some reason, a great dearth of manhole covers. This, combined with the black-out and a certain partiality for indulgence in the local "vino" on the part of our troops, made me familiar with a syndrome characteristic of the place. The essential features were a laceration of one supra-orbital region, occurring late at night in a somewhat alcoholic member of the Armed Forces. There was sometimes a concomitant abrasion of the shin, but this was usually trivial. Cases of this syndrome were seen at the rate of one a night on an average, and I was more annoyed than surprised when I was summoned from bed one winter night to yet another case. He appeared quite typical at first, except that the degree of alcoholisation was rather more profound than usual, and some difficulty was experienced in getting him to the theatre under his own steam. I was in the middle of my surgical procedure, conducted under local anæsthesia, when the patient announced with a great wail of distress that he had gone blind. I was taken aback by this and cursed myself for allowing my somnolence to make me omit even a cursory examination of the central nervous system: there had recently been a few cases of blindness among American troops in the neighbourhood who had drunk wine fortified by the natives of the place with methyl alcohol. Telling the patient not to worry I hastily completed my operation and proceeded to a more detailed examination. On inspection of the eyes it appeared to my relief that the cause of his ocular symptoms had been merely an alcoholic inability to open the eyes voluntarily. "Thank God, doctor," said the patient, with a cry of relief at his deliverance. "I can see quite all right now. You know, doctor," he added, "you're the most beautiful sight I've seen for ages." Even my wife hardly ever says that to me. But then she hardly ever touches alcohol.

* * *

In medieval times the view that disease in general, and plague and pestilence in particular, was a punishment for sin, was deep-rooted in the minds of men: and the gradual elimination of this vigorous superstition has been achieved slowly with the advance of medical knowledge and better understanding of the nature of disease. Through the accidental circumstances of their usual method of transmission, the venereal diseases, and these alone, still incur the judgment and condemnation of the stern moralist. Perhaps it is to the religious convictions of our forefathers, therefore, that part of the abnormal response to fear of these conditions must be attributed. The effects are variable and depend largely on mental balance and stability, but the apparently normal are not without their idiosyncrasies.

In better times, at this season of the year, it has been customary for our clinic to be invaded by workmen who render us acutely uncomfortable for a time, but leave us neat and shining with a coat of glossy paint. Sometimes they have expressed fears of contagion, but the rough and ready reassurance of our permanent staff has sufficed to calm these fears. This year we had to be content with a washdown of the walls and distemper on the ceilings. This year, too, the consternation of the workmen was exceptionally violent, and our technique of reassurance, spiced with ripe comment, failed to satisfy. The workmen were off their food, and the foreman's wife sternly forbade him the solace of the connubial bed until the danger was past. It was a bitter pill to us that we could *not* reassure them, and that our own year-long heroic defiance of the danger went for naught. Yet it had its advantages. It is long since men were seen to work so hard. The spirit and devotion of Dunkirk and D-day were born again, and wonders were wrought with almost incredible rapidity. It is hard to believe that sympathy with the foreman's predicament was the compelling factor, and the result must be attributed to a desire to restrict the period of danger. We are prepared, at a fee of course, to give advice to working parties on the proper application of the spirochætal spur and the gonococcal goad.

* * *

How quickly does fame depart! A recent examination of candidates for a postgraduate diploma in child health produced the favourite chronic arthritis child who is always a good topic for cross-examination—of the candidate. The usual gambit led up to the name of Still. The usual question as to who Still was produced the unexpected answer that he was an American. Lend-lease is all very well but this is going too far. It conjured up visions of George Frederic having an academic discussion with Andrew (somewhere in the shades) on the use of chiropraxis in the treatment of chronic arthritis in childhood. However, medical history is not a compulsory subject, so this candidate fared better than the one who remarked "If the W.R. excludes G.C., it's O.K."—surely the maximum of error combined with the maximum of irritation.

Mr. Victor Bonney, admitted to the fellowship earlier in the day. Without going so far as to apply the parable of the lost sheep, Mr. Gemmell admitted that "there is more joy in our ranks because he has joined us than there would be over any other man."

Sir HUGH LETT, president of the British Medical Association, in reply, said that today no-one would be bold enough to put the question "is your college really necessary?" Before the college was founded the situation of surgery, medicine, and obstetrics recalled the old-fashioned bicycle in which there were two big wheels and a little one which ran behind without anybody noticing. Discussing the organisation of a statutory service, Dr. G. F. Keatinge said it would not do to put the responsibility of medical supervision on the existing examining surgeons, because they can only give a limited amount of time to the work; besides, their approach is personal instead of being environmental and occupational. He thought that a corps of specialists in industrial medicine should be formed, to be called occupational health officers. They would be the next link in the chain after the school medical officer, supervising conditions for the worker from his entry to industry to the end of his working life.

Many speakers noted that while the industrial medical officer can recommend alterations in working conditions, he has at present no authority to demand them. As a State servant he would be able to insist that workshops were maintained at the statutory level; though, as Dr N. J. Cochran remarked, this might limit him, too: an intelligent doctor employed by the firm could suggest improvements beyond the statutory level.

It was generally agreed that industrial health research falls short in scope, speed, and operation.

The General Register Office

The branches of the office which were evacuated to Blackpool at the beginning of the war have now returned to Somerset House, London. The Registrar-General and a small staff remained at Somerset House throughout the war, but the general work of the office has been carried out at Blackpool. The records of births, deaths, and marriages were arranged and indexed there and then sent to Somerset House to be kept in the vaults. The whole of the office is now housed in London, except a part of the statistical branch and the whole of the Central National Registration Office which remain at Southport.

Infectious Disease in England and Wales

WEEK ENDED SEPT. 21

Notifications.—Smallpox, 0; scarlet fever, 853; whooping-cough, 1610; diphtheria, 240; paratyphoid, 17; typhoid, 13; measles (excluding rubella), 1208; pneumonia (primary or influenzal), 312; cerebrospinal fever, 36; poliomyelitis, 28; polio-encephalitis, 3; encephalitis lethargica, 1; dysentery, 66; puerperal pyrexia, 106; ophthalmia neonatorum, 69. No case of cholera, plague, or typhus was notified during the week.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (1) from an enteric fever, 1 (0) from measles, 6 (0) from whooping-cough, 3 (2) from diphtheria, 38 (3) from diarrhœa and enteritis under two years, and 5 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 266 (corresponding to a rate of 30 per thousand total births), including 41 in London.

In England Now

A Running Commentary by Peripatetic Correspondents

THE "squatters" have only recently burst on astonished newspaper readers. But the game is not new, as several hospitals can testify. One hospital urgently needed a large house and actively tried to obtain it. But the process of purchase and derequisitioning takes an amazingly long time and the house stood empty for months. So the homeless understandably assumed that since the war-time residents had long since gone, no-one was coming in; so in they went. How to get them out is another matter, but if the "usual channels" in Whitehall had not been so long, twisting, and clogged the trouble would never have arisen.

Another hospital, warned of its friend's dilemma and being itself endowed with the experience of many centuries, bought a house, and, since on the day it was derequisitioned the keys were not forthcoming, it applied padlocks to the outside of all the doors just to make sure. Thereafter it could set applications for licences in motion in a fairly secure frame of mind, and in the hope that its bombed-out nurses might some day find a resting place. But alas, that was too easy. The applications having gone the rounds for some two months and no answer having arrived, the premises had to remain unoccupied, and a new requisition order was issued by a different authority. And so the battle for derequisitioning started all over again. Meanwhile the nurses are thinking of doing a bit of squatting on their own account.

* * *

It was balm to me, as one of that ignorant class who learn most of their nutritional theory and practice from the daily press, to read in my evening paper the suave statement that "the reduction in the extraction-rate, nevertheless, will mean that bread will have a greater nutritional value, as the 5 per cent. reduction is equivalent to that amount less bran going into the bread." And, having read it, I was immediately in an awful state of mental conflict. Did not this contradict the assurances, so smoothly proffered, that previous increases were all *for the good* of our health and "nutrition"? Had I not read not so long ago an opinion of one of the Highest, that the (then) darker loaf was to contain more and more of five specified things and of a sixth class "some of them possibly not yet discovered"?

Well, I took the trouble to look it up, and I *had* read it all. I now suspect that these dizzy changes in our extraction-rate are but one voice in an elaborate counterpoint, grandly interpreted by the Public Relations Officer virtuoso on an instrument composed of "our medical and scientific advisers." I was pained to find how often I had meekly made a virtue of a necessity, gobbled up temporary surpluses, and skated round less temporary shortages. Of course I do not know whether the statement which set me inquiring was, or was not, part of an official hand-out. Perhaps it came from the Opposition. I hope it did; otherwise I could only say to the official spokesmen "Bah! Eat your words—they're so nutritious."

* * *

This complex modern life has given rise to an ever-increasing number of occupational diseases, and the participants in such a characteristically civilised activity as a world war have added their quota of martyrs to the inventive genius of mankind. For example, that vehicle of death, the jeep, has so often traumatised the posteriors of its hardy occupants and caused inflammation to arise in previously unsuspected pilonidal sinuses that the American Army Medical Corps has dubbed this complaint jeep disease.

But places and circumstances as well as machines have their own particular hazards. I well remember a winter spent in a much-bombed Italian market town, where there was, for some reason, a great dearth of manhole covers. This, combined with the black-out and a certain partiality for indulgence in the local "vino" on the part of our troops, made me familiar with a syndrome characteristic of the place. The essential features were a laceration of one supra-orbital region, occurring late at night in a somewhat alcoholic member of the Armed Forces. There was sometimes a concomitant abrasion of the shin, but this was usually trivial. Cases of this syndrome were seen at the rate of one a night on an average, and I was more annoyed than surprised when I was summoned from bed one winter night to yet another case. He appeared quite typical at first, except that the degree of alcoholisation was rather more profound than usual, and some difficulty was experienced in getting him to the theatre under his own steam. I was in the middle of my surgical procedure, conducted under local anæsthesia, when the patient announced with a great wail of distress that he had gone blind. I was taken aback by this and cursed myself for allowing my somnolence to make me omit even a cursory examination of the central nervous system; there had recently been a few cases of blindness among American troops in the neighbourhood who had drunk wine fortified by the natives of the place with methyl alcohol. Telling the patient not to worry I hastily completed my operation and proceeded to a more detailed examination. On inspection of the eyes it appeared to my relief that the cause of his ocular symptoms had been merely an alcoholic inability to open the eyes voluntarily. "Thank God, doctor," said the patient, with a cry of relief at his deliverance, "I can see quite all right now. You know, doctor," he added, "you're the most beautiful sight I've seen for ages." Even my wife hardly ever says that to me. But then she hardly ever touches alcohol.

* * *

In medieval times the view that disease in general, and plague and pestilence in particular, was a punishment for sin, was deep-rooted in the minds of men; and the gradual elimination of this vigorous superstition has been achieved slowly with the advance of medical knowledge and better understanding of the nature of disease. Through the accidental circumstances of their usual method of transmission, the venereal diseases, and these alone, still incur the judgment and condemnation of the stern moralist. Perhaps it is to the religious convictions of our forefathers, therefore, that part of the abnormal response to fear of these conditions must be attributed. The effects are variable and depend largely on mental balance and stability, but the apparently normal are not without their idiosyncrasies.

In better times, at this season of the year, it has been customary for our clinic to be invaded by workmen who render us acutely uncomfortable for a time, but leave us neat and shining with a coat of glossy paint. Sometimes they have expressed fears of contagion, but the rough and ready reassurance of our permanent staff has sufficed to calm these fears. This year we had to be content with a washdown of the walls and distemper on the ceilings. This year, too, the consternation of the workmen was exceptionally violent, and our technique of reassurance, spiced with ripe comment, failed to satisfy. The workmen were off their food, and the foreman's wife sternly forbade him the solace of the connubial bed until the danger was past. It was a bitter pill to us that we could not reassure them, and that our own year-long heroic defiance of the danger went for naught. Yet it had its advantages. It is long since men were seen to work so hard. The spirit and devotion of Dunkirk and D-day were born again, and wonders were wrought with almost incredible rapidity. It is hard to believe that sympathy with the foreman's predicament was the compelling factor, and the result must be attributed to a desire to restrict the period of danger. We are prepared, at a fee of course, to give advice to working parties on the proper application of the spirochætal spur and the gonococcal goad.

* * *

How quickly does fame depart! A recent examination of candidates for a postgraduate diploma in child health produced *the favourite* chronic arthritis child who is always a good topic for cross-examination—of the candidate. The usual gambit led up to the name of Still. The usual question as *to* who Still was produced the unexpected answer that he was an American. Lend-lease is all very well but this is going too far. It conjured up visions of George Frederic having *an academic* discussion with Andrew (somewhere in the shades) on the use of chiropraxis in the treatment of chronic arthritis in childhood. However, medical history is not a compulsory *subject*, so this candidate fared better than the one who remarked "If the W.R. excludes G.C., it's O.K."—surely the maximum of error combined with the maximum of irritation.

Letters to the Editor

MILITARY SERVICE FOR MEDICAL STUDENTS

SIR,—Your leader of Sept. 21 discusses alternative ways in which medical students may meet their obligation of military service. As you point out, the more useful and more convenient—namely, to serve after qualifying —will be impracticable for the next two years or so. May I then suggest another possibility which I believe would meet the present situation as well as future requirements ?

Why not split up the whole term of military service for medical students into two independent periods ? The prospective doctor could serve the first half of his term conveniently between school and university, thereby filling at least part of the interval that will elapse before he finds his place at a medical school. During this time he would have a general ordinary military training with the rank and file, though of course not a complete technical training in any of the specialised weapons and highly mechanised military craft which he does not require. Later, after qualification, he would complete his term of military service as a junior Service medical officer. This scheme proved its merits in Imperial Germany before, and with appropriate modifications during, the first world war.

Such a system would not only provide all the advantages and opportunities of the second alternative outlined in your leader but would also have some additional effects beneficial both to the doctor and to the fighting men under his care. (1) The medical student need not sacrifice too much of his precious time to purely military training but still has all the benefit a healthy young man can derive from military life. (2) During his shortened military training he acquires an intimate first-hand knowledge of the sort of job the soldier (or sailor or airman) has got to do. (3) If, as he should, he serves with the rank and file instead of with a selected group he gets to know something of the mentality of the ordinary man. This will stand him in good stead in civilian as well as military practice. (4) Last, but not least, he sees some of the methods and tricks used by comrades to evade duty. This knowledge will help him considerably as a doctor in assessing his patients' complaints.

Wolsingham, Co. Durham. E. G. W. HOFFSTAEDT.

A SYNDROME SIMULATING ACUTE ABDOMINAL DISEASE

SIR,—The letters following our paper of August 24 have suggested two possible explanations of the group of cases that we described—infective hepatitis and Bornholm disease.

Dr. Oram suggests that subicteric forms of infective hepatitis could have caused the syndrome. We agree that acute abdominal symptoms, rarely simulating surgical emergencies, may usher in the early stages. But at the time our wards contained many cases of obvious infective hepatitis, not one of which showed the syndrome described. It seems unlikely that subicteric cases would show more severe symptoms.

The question of Bornholm disease requires more careful consideration, and we admit that it might well have been included in the differential diagnosis. Neither of us has had experience of this disorder, which from the multiplicity of the symptoms described would appear to include a variety of pathological conditions. We are grateful to Dr. Evans for drawing our attention to Dr. Scadding's excellent article,[1] but our cases differ considerably from his, the symptoms being mostly abdominal while his were mainly thoracic. Pleural rub was absent in all our patients. We rejected an epidemic origin of our cases (perhaps wrongly) because they were unrelated, and because no minor varieties of the same syndrome were seen on the medical side of the hospital, as might have been expected in an epidemic. We are aware that a small percentage of cases of Bornholm disease may simulate abdominal emergencies, but nearly 100% of our cases presented with acute abdominal symptoms. The hypothesis that abortive staphylococcal retroperitoneal infection could be the cause of the syndrome was suggested to us because one of our cases developed a perinephric abscess. Dr. Evans objects to this hypothesis and says that one of his cases had a tuberculous apical abscess "but this does not make the rest tubercular." However, we stressed the perinephric abscess because it was possibly a significant lesion. It was capable of providing an explanation which we put forward quite humbly. At least it may stimulate inquiry, and should it be correct it will have rescued a series of cases from the dumping ground of varied conditions called Bornholm disease. Incidentally we wonder if Dr. Evans has noticed a letter from Dr. Cayley[2] on "The apparently acute abdomen in pulmonary tuberculosis."

MYTH AND MUMPSIMUS

SIR,—I regret that Dr. Forbes in his mention of lumber that should be thrown on the rubbish-heap did not include our antiquated Imperial system of weights and measures. I can recall the expectation fifty years ago that in the next *British Pharmacopœia* the metric system would be in sole use. What is the explanation of the retention of the older system ? Is it a wise *caution*, or is it just pure thrawnness ? It is not a mere question of nomenclature. A scientific system like the metric would tend to create a scientific outlook in its users.

Knock, Belfast. R. M. FRASER.

TUBERCULOUS ENDOMETRITIS AND STERILITY

SIR,—Your annotation of Sept. 7 says:

(1) "The association between sterility and tuberculous endometritis has been recognised only in the last few years. . . ."

(2) "His [Halbrecht's] conclusion that occult, subclinical tuberculous endometritis is one of the cardinal causes of sterility in general and of tubal occlusion in particular may have come as something of a shock to English workers. . . ."

(3) "It will be interesting to see whether, with further experience, similar reports appear in this country."

These statements require correction, not only in the interests of scientific accuracy but also because of the implication that the knowledge, to say nothing of original research, was new to "English workers." Only a few of the main facts can be dealt with here, but we should like to present a more accurate picture of the present-day knowledge of the relationship between tuberculous endometritis and sterility. A detailed account is, in fact, at present in the press, forming a portion of a paper being read by one of us (Sharman) at the Congress of the South African Medical Association this month. A study is made of 94 cases of tuberculous endometritis in a consecutive series of 1712 cases of primary sterility (5·5%) —this is the largest series ever recorded.

In 1943 one of us (Sutherland [1]), in a paper on Unsuspected Tuberculosis of the Endometrium, discussed at length the clinical aspects and pathology of the condition: the literature was fully reviewed. It was pointed out that the high incidence of sterility in endometrial tuberculosis was striking and that this causal factor had been stressed by Steinsick (1922),[2] Daniel (1925),[3] Halban and Seitz (1926),[4] and Vogt (1928).[5] The incidence was given as 7·2% in 212 patients (Steinsick), 7·0% in 71 patients (Schockaert and Ferin[6]), and 5·1% in 390 patients (Sharman). No relevant reference was found prior to 1922, not even in the excellent and exhaustive monograph by Norris in 1921.[7] In 1943 one of us (Sharman [8]) reported to the Royal Society of edicine a series of 840 cases of primary sterility, of hich 42 (5%) showed endometrial tuberculosis.

[7] Norris, C. C. Gynecological and Obstetrical Tuberculosis, New York, 1921.
[8] Sharman, A. *Proc. R. Soc. Med.* 1943, 37, 67; *J. Obstet. Gynæc.* 1944, 51, 85.

One of us (Sutherland[1]) has pointed out that it is irly easy to understand why this high incidence of ndometrial tuberculosis in cases of sterility has not een more generally recognised.

(*a*) Routine histological examination of the endometrium as often omitted in the past, but in recent years has been rried out more generally in order to obtain evidence of vulation.

(*b*) The isolated and infrequent lesions of one type of endo- etrial tuberculosis are easily overlooked as they are small nd scanty. With increasing experience one's visual acuity or the lesions is correspondingly increased, but in many ases they are found only after diligent search.

(*c*) Even when the lesions are seen, their tuberculous nature s often not obvious to the observer with an inadequate ackground of general pathology.

(*d*) It is possible that the increasing incidence of tuber- ulosis in general may also apply to tuberculosis of the ndometrium.

The prognosis in the subclinical type is good from the point of view of the patient's general health: systemic extension is uncommon. But the fertility prognosis is well-nigh hopeless. not one of our 64 cases, followed up for more than a year, having become pregnant. This is not entirely due to tubal occlusion caused by tubal tuberculosis, since, although every case of endometrial infection has an associated tubal one, complete occlusion has been found only in 62% of cases of endometrial tuberculosis.

A large amount of work on this interesting subject may be synopsised as follows: (1) careful study of endometrium in cases of primary sterility will show unsuspected endometrial tuberculosis in a minimum of 5·5% of cases: and (2) tubal occlusion, in the absence of palpable adnexal swellings, is due to tubal tuberculosis in a large proportion of cases.

ALBERT SHARMAN.
ARTHUR M. SUTHERLAND.

NEW WORDS ABOUT OLD AGE

SIR,—Dr. Vertue is perfectly correct when he states that there is no word *geria* in Greek. But there is a word *geras*, the common word for old age, the stem being *ger(a)*, the root being *g(e)r*, from which comes also *graus*, an old woman. The *-ia-* in the middle of the word belongs, of course, to the second part of it, not to *ger*—as indeed Dr. Vertue recognises in forming "gerontiatrics." Why the newly named science should be exclusively applied to men is not clear: after all, old women preponderate. *Geron* never means "an old person," always "old man," "elder," "senator": so it would be as logical to use *graus* for the word and talk of "griatrics." However, for the sake of euphony and neatness, "geriatrics" is preferable: it is justified by derivation, and is indeed the only word properly to be applied (the sole alternative being the harsh "geroiatrics").

Edinburgh.

GORDON IRVINE.

PENICILLIN IN WOUND EXUDATES

SIR,—The results of the brilliant piece of research by Lady Florey and her colleagues (Sept. 21, p. 405) will no doubt stimulate other workers to produce the ideal medium for prolonged local application to wounds. That this has exercised the minds of military surgeons for some time can be gleaned by the perusal of the 21 Army Group publication, *Penicillin Therapy and Control*. One extract on pp. 114–115 reads:

> "Deep Wounds with or without bone involvement.—Plugs should not be used, as during a battle when hurried evacuations occur the plug may not be removed for several days. Then granulations grow into the meshes and removal is difficult, and this is still more likely to happen in open fractures if the jagged bone ends become entangled. It is suggested plugs of penicillin wax might be used by those who feel they are indicated. These would cancel themselves out in transit and supply a prolonged local application of penicillin."

B.L.A. SURGEON.

ARSENICAL CHICKENPOX

SIR,—I can add another case to those described by Dr. Parkes Weber (Sept. 14) in which a patient who suffered from herpes zoster while having arsenical treatment apparently infected a child with varicella.

In 1932 a patient in hospital suffering from tabes dorsalis had two or three injections of neoarsphenamine and then developed herpes zoster of the ophthalmic division of the right trigeminal nerve. About a fortnight later another patient in the same ward developed a zoster eruption involving two or three dorsal segments, and a boy, aged ten years, developed a mild attack of chickenpox. The boy, who had an internal hydrocephalus, died a few days later, and at necropsy was found to have a congenital septum of the aqueduct of Sylvius. It may be contended that the arsenical treatment and the attack of herpes zoster in the first patient were not related, but it is by the accumulation of such happenings that it may be possible to establish a more precise relationship between arsenical treatment, herpes zoster, and varicella.

Harrogate.

T. G. REAH.

DESOXYCORTONE AND ARTHRITIS

SIR,—Dr. Harrison has drawn my attention to Dr. Jennings's letter in your issue of Sept. 7. Despite Dr. Harrison's generous acknowledgment of my help (August 10, p. 215), my advice before the publication of his paper of June 1 (p. 815) was limited to explaining how to apply the chi-squared test to the facts as presented in table I of that article. The figures given in that table do not alone provide sufficient evidence to establish the hypothesis that adrenalectomy and thyroidectomy increase the rat's prospects of developing arthritis. I advised Dr. Harrison in this sense in September, 1945.

Dr. Harrison next consulted me in August, 1946. He sought advice in replying to Dr. Jennings's letter in the *Lancet* of July 20, in which Dr. Jennings suggested that there were fallacies in the statistical technique which Dr. Harrison had applied to the facts as presented in his table I. With my help, Dr. Harrison replied to these suggestions in his letter of August 10.

Dr. Jennings's remarks of Sept. 7 are therefore inappropriate. In this case, the "expert behind the scenes" neither "bullied" nor "threatened with specialised profundities." but gave advice on the interpretation of the facts as given in table I. He did not "really collaborate" because he was not invited to do so: he first heard of Dr. Harrison's paper in the *Lancet* after it had been published.

Dr. Jennings may argue that Dr. Harrison should have asked a statistical expert to go through both his paper and that of Professor Selye line by line with him, before he appeared in print: but he surely would not wish the expert to "bully" Dr. Harrison into doing this. I agree with Dr. Jennings that scientists would profit by asking fuller collaboration from statistical experts in the experimental as well as the statistical aspects of their work. Such collaboration is being developed at Oxford, and the understanding, now gradually growing, between scientists and statisticians will no doubt be advanced by Dr. Jennings's Pickwickian and (if I may return his compliment) Jabberwockian correspondence.

Dr. Jennings asserts that Dr. Harrison was claiming "statistical proof of his rightness." Actually, Dr. Harrison merely claimed that the facts as stated in his table I were not sufficient in themselves to establish Selye's hypothesis: he did not claim that they proved Selye's hypothesis wrong. Dr. Jennings points out that Professor Selye quoted evidence additional to that given in table I, and that, when this evidence is taken into account as well, he can disprove Dr. Harrison's hypothesis and establish that of Professor Selye. In particular, Dr. Jennings refers to information about rats which died during the experiment. This may be a point of substance, but as Dr. Jennings has not provided the details of his statistical proof it is not possible to pass judgment on its validity.

In a controversy of this kind, the statistician's aim should be to assist in a correct interpretation of the evidence. If Dr. Jennings and Dr. Harrison would produce a precise formulation of the evidence, stating in particular which of the dead rats had developed arthritis, and if Dr. Jennings then set out his proof from that evidence that Dr. Harrison's hypothesis about rats was wrong and Professor Selye's hypothesis was correct, then the statistical experts should be able to pass impartial judgment supporting (or discrediting) his proof.

I heartily endorse Dr. Jennings's plea that medicine should keep in touch with statistics and vice versa: although since the statistician should also cover biology, astronomy, agriculture, psychology, economics, and the other social sciences, he must confine himself to their statistical aspects.

Institute of Statistics,
University of Oxford.
D. G. CHAMPERNOWNE.

TUBERCULOUS ABSCESS FOLLOWING INTRAMUSCULAR PENICILLIN

SIR,—In their article of Sept. 14 (p. 379) Mr. Ebrill and Dr. Elek say they were unable to find the source of the infection, though it was probably exogenous. In most penicillin drip set-ups there is a weak point that I have often tried to get rectified, but I have always met with the objection that the drip will stop flowing if my advice is followed. The weak point is the air-intake, which should be guarded with a cotton-wool filter to exclude organisms; without the filter a pint of solution is gradually replaced by a pint of bacteria-laden air from the ward. I do not suggest that a filter was omitted on this occasion; what often happens is that someone removes the cotton-wool from the filter for "practical" reasons.

Tubercle bacilli are not uncommon in the dust of hospital wards. It is not surprising that abscesses form at the site of injection; the surprising thing—a testimonial to the vis medicatrix naturæ—is that there are so few of them.

Epping, Essex.
FRANK MARSH.

DEATH AFTER CURARE

SIR,—In your annotation of Sept. 21 you report that the pathologist considered that the death of a patient after an operation was due to toxæmia and had been accelerated by respiratory failure due to curare. The effect of curare wears off rapidly and I do not believe that it causes respiratory depression 43 minutes after administration. The patient was 70 years of age and the anæsthetic used was 'Pentothal.' It is my experience that a high proportion of elderly patients tolerate intravenous barbiturates extremely badly and that delayed recovery after intravenous anæsthesia is common among patients of any age. I know of two elderly men who never recovered consciousness after being given this anæsthetic for the performance of emergency suprapubic cystotomy. We have all seen the young healthy adult who took a very long time to wake up.

Pentothal is a drug which should be used with the greatest caution, and it is unfortunate that so many practitioners have been encouraged to administer an intravenous anæsthetic when some inhalation technique could be used. In this country we are too ready to publish our successes and too reluctant to report our fatalities. If one studies the American journals one can obtain a more accurate appreciation of the dangers of "modern anæsthesia," which I do not find to be as safe or satisfactory as ether. As Flagg rightly says, "Far too many anæsthetists have tried too often to avoid the use of ether anæsthesia, and the skill with which it might be used is not so much in evidence today as it might be." If our medical students and newly qualified practitioners were taught to understand the value and wide range of usefulness of ether we should read of far fewer deaths under anæsthesia being inquired into by the coroners' courts.

All that is modern and new is not progressive, and we might well ponder on the fact that when ether and chloroform were used almost exclusively in England the number of deaths associated with anæsthesia reported to the coroner in one year was 347, whereas in 1941 it was 835. This in spite of the fact that far greater surgical risks were accepted in those days, and that restorative measures were not very satisfactory. We also no longer see the neglected abdominal emergency, once a common cause of operating-room deaths.

I cannot help feeling that in the case you mention th cause of death was the pentothal rather than the curar Curare may be a highly dangerous drug—we do not y know—but do not let us blame it for the offences o another drug.

New Barnet, Herts.
JOHN ELAM.

SIR,—Your annotation of Sept. 21 on the death of patient following an operation during which curare ha been administered was marred for me by the fact that i did not contain the information, which cannot be to widely spread, that in physostigmine (eserine) or 'Pro tigmin' we have an antidote for curare. 'Coramine or 'Veritol' are of no value for counteracting thi substance. No anæsthetist should administer curar unless he has readily available an injection of eserin (1 mg.) or prostigmin (2·5 mg.).

JAS. D. P. GRAHAM.
Dept. of Materia Medica, Glasgow University.

AMŒBOMA AND CARCINOMA

SIR,—Mr. M. J. Smyth's article of Sept. 14 is of particular value in drawing attention to a subject which is not familiar to those who have been denied the opportunities of tropical practice. From time to time examples of amœboma of the rectum will occur in this country and only careful differential diagnosis will prevent surgical disasters.

Amœboma of the rectum is one of the rarer forms o intestinal amœbiasis, and even in tropical countries n one surgeon is likely to see many examples. It may present as an ulcer or as a papilliferous overgrowth, and in either form may appear indistinguishable from carcinoma. The diagnosis, however, will rarely present much difficulty to those who follow Mr. Smyth's advice —that any tumour of the colon or rectum discovered in a patient who has served in the East should be regarded as amœboma rather than carcinoma until thorough pathological examination has proved otherwise. This should apply to all patients who have at any time been exposed to amœbic dysentery, whether they give a history of dysentery or not, and even if they have been discharged as cured of this disease, so noted for its tendency to relapse.

Repeated examination of the stools and of scrapings from the surface of an amœboma may fail to disclose the *Entamœba histolytica*. On the other hand, as Mr. Smyth reminds us, the presence of the *E. histolytica* does not exclude carcinoma. Fortunately in emetine we have a valuable aid to diagnosis. Whether *E. histolytica* has been found or not, before resorting to operation a course of this drug should be given, its effect being checked by repeated sigmoidoscopy. As a general rule the amœboma very rapidly responds, but only a complete resolution can be accepted as proof that the lesion is amœbic. If this is not obtained biopsy must be done.

During four years' military service in endemic areas, I saw six examples of amœboma of the rectum which simulated carcinoma. Five of these resolved completely on medical treatment alone. The sixth patient was admitted as an advanced case of carcinoma of the rectum, and the clinical condition was consistent with this diagnosis. When repeated examination of the stools and of the discharge from the surface of the tumour proved negative, colostomy was proposed; but a proctoscopic examination made on the operation table produced a specimen containing many typical *E. histolytica* and operation was therefore postponed. Emetine was given but the patient died within a few days. Post-mortem examination revealed how futile a colostomy would have proved, for the whole length of the colon was involved in a diffuse amœbic ulceration. These cases are reported in *Surgery, Gynecology and Obstetrics* (1945, 81, 387) and the *Liverpool Medico-chirurgical Journal* (in the press).

It would be unfortunate if Mr. Smyth's statement "I have no doubt that in amœboma of the rectum colostomy is helpful rather than otherwise" were to encourage the frequent performance of this operation. Whereas in the vast majority of cases of rectal amœboma medical measures result in a rapid and complete disappearance of the lesion, colostomy exposes the patient the risk of spreading amœbic infection of the wound d to serious hepatic complications. In rectal amœbiasis fection of the cæcum and proximal colon must be sumed even in the absence of clinical signs, and testinal obstruction of a type which requires a colosmy so urgently that emetine cannot first be given a ial must be very uncommon. Colostomy may of course needed in the rare event of failure to respond to nœbicides, or when dealing with complications such as tractable fistula.

Liverpool. PHILIP HAWE.

SIGN OF SUBMERGED GOITRE

SIR,—There is a useful sign given by a submerged or trathoracic goitre which I have employed and taught r many years. It consists in getting the patient to evate both arms until they touch the sides of the head; ter a moment or so, congestion of the face, some anosis, and lastly distress become apparent—presumoly from narrowing of the thoracic inlet and obstruction the venous return. I have not seen it in superior ediastinal block.

Doubtless the sign has been described before and even ears a name, but I am unaware of it.

Liverpool. H. S. PEMBERTON.

HOSPITAL PHOTOGRAPHIC DEPARTMENT

SIR,—To your issue of August 31 Dr. Hansell and r. Stanford contribute most interesting articles on edical photography. Both see the necessity of adequate pparatus and premises, but their ideas on personnel specially Dr. Stanford's) seem extremely wasteful. hy should a request for a photograph be so vague as need a qualified medical man to interpret it? Surely ose who request are the ones to be taught to know hat they want and to appreciate its uses.

How often are photographs praised merely for their etail without regard to whether they show off the ondition; or requests made at absurdly short notice r theatre work, showing only too clearly the general norance of the hospital of how to get the best out of s photographic department.

The time has come when medical photography should a subject in our medical schools, clinical photography eing on an equality with radiology. Then we will not eed to waste doctors by putting them in photographic epartments as elaborate buffers to the ignorance of eir brothers on the staff. A photographer with really ide experience is essential, and once he or she has a ertain amount of medical knowledge, the doctor who as "joined his hobby to his profession" becomes an xtravagant and unwanted figurehead.

No photographer, if he is wisely chosen, needs a nurse's aining to treat his patients with kindness and conderation.

SYLVIA TREADGOLD
Photographer-in-charge.
Photographic Dept., Guy's Hospital, London, S.E.1.

CHRISTIAN SCIENCE

SIR,—The Chadwick lecture published in your issue f Sept. 21 (p. 427) contains a reference to Christian cience which I should like to correct.

Christian Scientists do not regard disease or other ills merely imaginary. Christian Science teaches that ckness and disease, and other ills, are phases of the elief in an existence apart from God. It further teaches at these evils can be overcome, not by ignoring them, ut by correcting them intelligently by means of a right nderstanding of God and man and their relationship one another.

This question is fully developed in the Christian cience textbook, *Science and Health with Key to the riptures*, by Mary Baker Eddy, the Discoverer and ounder of Christian Science, and on p. 460 the attitude Christian Science to "the ills of the flesh" is briefly ated as follows: "Sickness is neither imaginary nor nreal,—that is, to the frightened, false sense of the atient. Sickness is more than fancy: it is solid convicon. It is therefore to be dealt with through right oprehension of the truth of being."

COLIN R. ÆDDISON.

Obituary

THOMAS WATTS EDEN

M.D. EDIN., F.R.C.P., F.R.C.O.G.

Dr. Watts Eden, who died at Torbay on Sept. 22, was consulting obstetric physician to Charing Cross Hospital, and consulting surgeon to Queen Charlotte's Hospital and the Chelsea Hospital for Women. A former editor of the *Journal of Obstetrics and Gynæcology of the British Empire*, he continued his association with the journal as chairman of the editorial committee and the board of directors.

Born in 1863, the son of Alfred Thomas Eden, of Evesham, he was educated privately and at the University of Edinburgh, where he graduated M.B. in 1888. Of his student days Sir Ewen Maclean writes: "I first met Watts Eden in connexion with the Drummond movement, which was inspired by the simple religious addresses given by Prof. Henry Drummond to his students in Glasgow. In this as in many other directions when effective speaking was required Eden's superb diction and delivery were in great demand. Though he was a year in front of me in the Edinburgh curriculum we contrived to room together, and I could not but envy as well as admire the apparent ease with which he assimilated notes and relevant parts of textbooks, gained medals galore, graduated with first-class honours, and was awarded the much-coveted Ettles scholarship. But despite his brilliant achievements and ability there was no aloofness about him, and in Edinburgh as later in London he made many warm friends."

(Press Portrait Bureau

After postgraduate years spent in Berlin, Leipzig, and Birmingham, Watts Eden came to London and joined the staff of the Chelsea Women's Hospital, where his colleagues included Fairbairn, Comyns Berkeley, and Victor Bonney. "I became acquainted with him," writes Mr. Bonney, "in 1898 when I went to Chelsea Hospital for Women as resident surgical officer. He had been attached to that institution, in a minor capacity, for a short time before the debacle which led to its reorganisation in 1894, and when the new staff was formed he was appointed assistant physician, a title subsequently changed to surgeon. He had already made a name for himself by a paper on the structure of the placenta which attracted much attention, and I remember him as a sparely made young man, somewhat sallow of complexion, with a kindly smile and a deliberate, though incisive, manner of speech.

"He formed one of that small band of surgeons, now alas all departed but one, who, by their devoted and earnest work, raised the reputation of the hospital from the zero to which it had fallen to the highest level of professional estimation, and with them he played a great part in putting abdominopelvic surgery on a sure foundation.

"His own reputation steadily grew. He became a member of the staff of Queen Charlotte's Hospital, and by the time that I went there as a resident officer he and William Gow stood head and shoulders above the rest of their colleagues."

In 1898 he was appointed to the staff of Charing Cross Hospital, where his gifts of clear thinking, writing, and expression quickly won him recognition as a great teacher. To this period belong his manuals of midwifery and obstetrics which have run into many editions, and later in collaboration with Dr. Lockyer he published *Gynæcology for Students and Practitioners*. Outside his own hospital he found time to examine for the universities of Oxford, Cambridge, Edinburgh, and Leeds, to serve on the council of the Royal College of Physicians of London, and to sit on the governing body of the British Postgraduate Medical School. During the first world war he held the rank of major in the R.A.M.C., and our portrait shows him at this period. In 1930 he was elected president of the Royal Society of Medicine and his American colleagues made him an honorary member of the American Gynecological Society. He interpreted the responsibilities of his specialty widely, and in his Lloyd Roberts lecture at St. Mary's Hospital, Manchester, in 1925, and in an address to the Oxford Medical Society in 1931, he put the case for the unborn child, urging his colleagues to beware of regarding the infant as the by-product of the confinement.

A member of the joint council of midwifery appointed by the National Birthday Trust, he was chairman of the committee which in 1935 presented a scheme for an organised national midwifery service designed to raise the status of the midwife, and even after his retirement he continued to take an active interest in the Midwives Guild of St. Breca. "It was my good fortune," writes Dr. Cuthbert Lockyer, "to be Dr. Eden's junior colleague at Charing Cross for many years, and during that time I learned to esteem and respect him. Although never robust, his industry was remarkable and even in retirement at Thurlestone he gave unselfishly of his strength in the promotion of the welfare of the Royal College of Obstetricians and Gynæcologists, of which he had been an active and influential founder. With his many interests he would spend whole weeks in London attending as many as 15–20 committee meetings before returning spent to his country home. Our coöperation in clinical work was uniformly harmonious, our collaboration in writing was a labour of love, and our friendship has been up to the last close and intimate."

In Mr. Bonney's words, "A long life filled with honourable work has come to an end, and viewing it as a whole certain great qualities of the man stand out clearly: a steady level-headedness, a wide humanity, an unassailable integrity, and a great dignity. These are the things which, beyond all else, procured him the respect and affection of those who worked with him, and the specialty, which he made it his life's work to serve, grieves at his passing, for he kept its flag flying very high."

In 1900 Dr. Eden married Miss May Bain, of Cockermouth, who survives him.

FRANK McCALLUM

M.B. MELB., D.P.H., D.T.M. & H.

THE death is announced of Dr. Frank McCallum, who just over a year ago was appointed director-general of health for the Commonwealth of Australia. Son of the late Rev. Alexander McCallum, D.D., of Melbourne, he was educated at Wesley College and Melbourne University. At the outbreak of war in 1914 he joined the A.A.M.C. at once, only interrupting his service to graduate M.B. in 1917. After holding a house-appointment at Cardiff Royal Infirmary, he returned to Australia in 1920 to take his D.P.H. at Melbourne and to join the Commonwealth quarantine service. During 1922 and 1923, with a Rockefeller travelling fellowship, he visited the United States and returned to this country to take his D.T.M. & H. In 1927 he was appointed director of the division of epidemiology of the Commonwealth department of health, and two years later became chief medical officer at Australia House in London. During this period he represented Australia on the permanent committee of the Office International d'Hygiène publique. In 1934 he became chief quarantine officer of the North Eastern division and in the same year senior medical officer of the administrative staff at the health department at Canberra. Dr. McCallum was 56 years of age.

N. M. G. writes: "McCallum was chiefly known in this country for his interest in international health work. While chief medical officer in London from 1929 to 1934, and afterwards, he often represented Australia at international public-health meetings and I well remember how greatly the tedium of a return from Paris to London was relieved by his quiet and likeable companionship. His little book—now scarce—on *International Hygiene*, published in 1935 by the department of health of the Commonwealth and based on lectures he gave at Melbourne University, was acknowledged to be the most useful publication in that field. His friends in this country will deplore his untimely death so soon after he had taken over the leading public-health post of his country."

Notes and News

TRAFFIC IN NARCOTIC DRUGS

THE secretariat of the League of Nations at Geneva h lately issued a summary of the annual reports for 1941 fr the countries party to the several opium and narcotic dr conventions (1912–36), with apology for unavoidable del The summary surveys the position of the narcotic dru traffic in the 67 contracting countries. China was said to b complacent at the completion of the "six-year suppress plan," and opium-smoking by overseas Chinese was to b taken in hand, while illicit cultivation and trade in man provinces in Japanese occupation was deplored. In t United Kingdom addiction to narcotic drugs, chiefly morphi was reported to be decreasing. The number of addicts 1941 was 503 (252 men and 251 women) of whom 89 w doctors. In India opium was being illicitly imported fr border countries and Afghanistan, and illicitly export to Burma and Ceylon from Bengal. In Canada there was s some addiction to codeine, and hypodermic injection smoking opium was being practised by occidentals a orientals on the Pacific coast—addicts have been kno to resort to the ointment of galls and opium to obtain morphine content. In Egypt the Central Narcotics Bure reported the continued smuggling of hashish and opi through Syria and Palestine, while the southern Sud was growing illicit hashish and sending it north on riv steamers.

As regards "raw opium" the area under poppy cultivati in India in 1941 was 1950 hectares, the whole of the produ being sold to the government opium factory at Ghazipu the consumption of "excise opium" for "medical, qua medical, and non-medical purposes" in 1941 was 136,822 k Five firms are licensed in the United Kingdom to manufactu narcotic drugs, and a like number in the United Stat From Colombia comes an urgent appeal, supported by t Apostolic Nuncio, for "reducing the cultivation of the co plant to the level of world medical requirements" an its habitual abuse is said to cause widespread ravages tuberculosis.

FOOD BULLETINS

King Edward's Hospital Fund for London circulat bulletins periodically to hospitals in which tested recipes a given to a wider public, current food problems are discusse and inquiries to do with food or catering are answered. T first bulletin, which appeared in May, contained notes o dried milk, and recipes for puddings without fat. The Augu bulletin discussed allowances for expectant and nursi mothers, and gave some recipes for breakfast dishes. A thi bulletin, nearly ready, will deal with the feeding of childre The fund's address is 10, Old Jewry, E.C.2.

MIDWIVES' PROGRESS

RETURNS made to the Central Midwives Board[1] by loc supervising authorities show that the number of midwives wh notified their intention to practise during 1945 was 16,680 some 300 more than in 1944. Of this number only 3 had bee in practice before 1902, when the Midwives Act was passe and only 10% had been enrolled before 1920. Some 78 midwives have been trained and enrolled under the mo recent rules of the Central Midwives Board, which hav operated since May, 1939. More than half of these wom were practising in 1945, and 90% of these were State-register nurses. Probably about 62% of practising midwives ar the peak period of their working lives—between the ages 27 and 47.

A great many women who do not intend to practise midwives take the board's examinations. There are 72, names on the register, and of some 14,000 midwives enrolled the six years 1936–41, only 24% notified their intention practise in 1945. This custom of training an excess of mi wives is not wholly extravagant, for the experience is doubtl useful to nurses who take up public-health work; inde employing authorities are apt to look for this qualificatio But it has the effect of reducing the numbers of cases availa for medical students, and it does not offer the prospecti public-health nurse a course ideally suited to her needs. would be useful to consider whether a more appropri certificate course might not be offered to nurses who do n end to practise as midwives, with less emphasis on delivery d more on the care of infants after the first month. The ard, with the approval of the Ministry of Health, have ended their rules to enable sick children's nurses to be mitted to a shortened period of training, not described in e report; and such a course might serve the purpose of her nurses who do not intend to practise midwifery.

---

[1] Report on the work of the Central Midwives Board for the y ended March 31, 1

In view of the present shortage of practising midwives the ard have decided that the time has not yet come to restore e rules, suspended in 1939, requiring midwives to attend st-certificate refresher courses; but they welcome the luntary schemes for providing such courses which many al authorities are supporting.

ASPHYXIA AND ANOXIA

WRITING in *Science* (1946, 104, 112), Prof. E. J. Van Liere otests against the misuse of the terms asphyxia and anoxia. e contends that during anoxia there is a diminished supply oxygen to the tissues, but there is no accumulation of CO_2 the alveolar air, or presumably in the tissues, because the sociated hyperpnœa washes the CO_2 out of the lungs. In phyxia, on the other hand, diminished oxygenation of the ssues is accompanied by an increase of CO_2 tension in the ood and tissues. He quotes Yandell Henderson's criticism at the term asphyxiated is well established but there is no uivalent term for a condition of anoxia: "Then let us eate one," says Van Liere: "the equivalent would be noxiated'." This term would certainly describe accurately e state of a man who has ascended to such a height that the ygen tension is too low to sustain life.

VITAL STATISTICS FOR JUNE QUARTER

THE Registrar-General's return for the June quarter H.M. Stationery Office, 6*d*.) confirms that the birth-rate as 19·2 per 1000 total population, the highest rate recorded any quarter since June, 1925. The total number of births as 203,797 and the proportion of boys to girls 1069 to 1000. irths exceeded deaths by 89,727, compared with an excess 64,252 for June quarter, 1945. Infant mortality, provisionally corrected, was 41 per 1000 related live births— per 1000 below the average of the previous ten June quarters. he number of illegitimate births was 14,789, this being 625 fewer than in June last year. Deaths numbered 114,070, presenting a death-rate of 10·7 per 1000 compared with [illegible]4 for June quarter, 1945, and an average of 11·6 for the revious five June quarters. Marriages totalled 100,814, n increase of 6620 over the average for the June quarters 941–45.

ART EXHIBITION FOR THE HOSPITALS

King Edward's Hospital Fund for London has organised loan exhibition of pictures from the collection of Sir Harold Vernher, K.C.V.O., at the Wildenstein Gallery, New Bond treet, W.1. The exhibition was opened by the Duchess f Kent on Oct. 2, and will remain open until Nov. 9. The harge for admission is 2*s*. 6*d*., and all proceeds will be given o King Edward's Fund.

---

niversity of Sheffield

At recent examinations the following were successful:

M.D.—H. B. Stoner.

Final M.B., Ch.B. examination.—Michael Redfern (with first-class onours); Derrick Dexter (with second-class honours).

ostgraduate Course at Leeds

A two-weeks' general refresher course for class 2 demobilised edical officers and insurance practitioners is to be held by the niversity of Leeds, commencing on Monday, Nov. 25. nquiries should be directed to the Senior Administrative fficer, School of Medicine, Leeds, 2.

oyal College of Physicians of London

Dr. D. Evan Bedford will deliver the Bradshaw lecture at the college, Pall Mall East, S.W.1, on Thursday, Nov. 7, at 5 P.M. He will speak on Hypertensive Heart Disease.

ociety of Medical Officers of Health

Sir Allen Daley, medical officer of health and school medical fficer, London County Council, will be installed as president this society for the session 1946–47, and will give his presiential address at a meeting to be held at Tavistock House, avistock Square, London, W.C.1, at 5.30 P.M. on Thursday, ct. 17.

British Institute of Philosophy

A course of five lectures on Contemporary World Outlooks will be delivered at 5.15 P.M. on Fridays from Oct. 11 to Nov. 8, at University Hall, 14, Gordon Square, W.C.1.

Central Council for Health Education

The council has lately formed a field work committee, and a materials committee. The chairmen are Dr. A. B. Williamson, M.O.H. for Portsmouth, and Dr. H. Maurice Williams, M.O.H. for Southampton.

Medical Photographic Exhibition

An informal display of medical photographic apparatus and records is to be held in the department of medical photography, Westminster Hospital School of Medicine, from Oct. 8 to 11, between the hours of 10 A.M. and 4 P.M.

West London Medico-Chirurgical Society

A dinner will be held on Friday, Oct. 18, at 7 P.M., at the South Kensington Hotel, 41, Queen's Gate Terrace, S.W.7. Dr. G. S. Hovenden will deliver the presidential address on Fifty Years of General Practice.

Medical Defence Union

At the annual meeting held in London on Sept. 24, Mr. St. J. Buxton was elected president, Dr. Henry Robinson treasurer, and Dr. G. Roche Lynch chairman of the council committee. Dr. Janet Aitken, Mr. Buxton, and Dr. Peter Macdonald were re-elected members of council. The union now has more than 30,000 members, all of whom are registered medical practitioners. The annual report is reviewed on another page.

Local Responsibility for Hospitals

In an address at the annual meeting of the Nelson Hospital, reported in the *Times* of Sept. 28, Sir Alfred Webb-Johnson, P.R.C.S., suggested that in the National Health Service the freedom given to the teaching hospitals should be extended not only to the hospital management committees but also to individual hospitals. Local interest and support would thus be retained, and opportunities for donors, and for funds such as King Edward's Hospital Fund and the Nuffield Trust, would be greatly extended. He hoped that Parliament would allow the largest measure of local responsibility for the planning and conduct of hospitals.

British Orthopædic Association

The association's annual meeting is to be held in London on Friday and Saturday, Oct. 18 and 19; the meeting will be held on the first day at the Royal Society of Medicine, 1, Wimpole Street, W.1, and on the second day at St. Thomas's Hospital, S.E.1. The programme on Oct. 18 begins at 9.30 A.M. with a discussion on Fractures of the Os Calcis, to be opened by Mr. N. W. Roberts and Mr. W. Gissane; this will be followed by Mr. George Perkins's presidential address on Rest versus Activity in the Treatment of a Fracture, and by short papers. There will be a dinner at Grosvenor House Hotel, Park Lane, W.1, at 7 P.M. The annual general meeting will take place at 9.30 A.M. on Oct. 19, and will be followed by a demonstration of cases.

Centenary in Anæsthesia

The section of anæsthetics of the Royal Society of Medicine is to celebrate next month the centenary of the first public administration of an anæsthetic. A reception by Sir Gordon Gordon-Taylor, the society's immediate past-president, will be held on Friday, Nov. 1, at 7.30 P.M. This will be followed by a buffet supper, after which Dr. E. S. Rowbotham, president of the section, will speak on A Hundred Years of Anæsthesia.

The Association of Anæsthetists of Great Britain and Ireland is marking the centenary of the first administration of ether in Great Britain with events on Oct. 30 and 31 and Dec. 21. At 8.30 P.M. on Wednesday, Oct. 30, the Princess Royal will unveil at the Royal College of Surgeons a plaque commemorating four pioneers in anæsthesia; the ceremony will be followed by a reception. On the morning of Thursday, Oct. 31, there will be operating sessions at various London hospitals; the annual general meeting will be held at the Royal College of Surgeons at 2 P.M., and at 7 P.M. there will be a dinner in the Great Hall of Lincoln's Inn. An exhibition of anæsthetic apparatus will be open at the Royal College of Surgeons from Oct. 29 to Nov. 1. On Saturday, Dec. 21, there will be a dinner-dance at the Dorchester Hotel.

Heberden Society

The annual general meeting of this society is to be held on Oct. 25 and 26, at 11, Chandos Street, London, W.1. At 4.45 P.M. on Friday, the 25th, there will be a discussion on Future Trends of Research in Rheumatoid Arthritis, when Dr. G. M. Findlay will speak on Arthritis in Rats and Mice due to Pleuropneumonia-like Organisms, and Dr. D. H. Collins on Erysipelothrix Polyarthritis of Swine. The annual dinner will take place at 7.45 P.M., in the Euston Hotel. On Saturday, the 26th, at 11 A.M., Prof. J. A. Höjer, chief medical officer of the Royal Swedish ministry of health, will read a paper on the Organisation and Work of a Rheumatic Service in Sweden. Further particulars may be had from the general secretary, Miss Bereton, 91, Priory Road, West Hampstead, N.W.6.

Louis Gross Lecture

Dr. Roy R. Grinker, director of the Institute for Psychosomatic and Psychiatric Research and Training of the Michael Reese Hospital, Chicago, will deliver the ninth Louis Gross lecture at the Jewish General Hospital, Montreal, on Wednesday, Oct. 23, at 8.30 P.M. He will speak on Psychiatric Objectives of our Time.

Return to Practice

The Central Medical War Committee announces that the following have resumed civilian practice:

Mr. D. J. MacRae, F.R.C.S., M.R.C.O.G., 10, Harley Street, London, W.1.
Dr. R. J. Twort, 11, Park Terrace, Nottingham (Tel. 66486).

WEAPON AGAINST MIDGES.—In reply to our peripatetic correspondent of Sept. 21, who wondered whether D.M.P. has yet got through to the civilian, Dr. A. R. Neligan writes that it has, in the form of 'Mylol' (Boots), and is proving invaluable against this autumn's clouds of midges.

Messrs. Allen & Hanbury inform us that they now have limited stocks of 'Rutin' available. The use of this drug in the treatment of increased capillary fragility was discussed in our columns on July 6, p. 16.

Births, Marriages, and Deaths

BIRTHS

BORLAND.—On Sept. 23, at Sunbury-on-Thames, the wife of Dr. A. K. Borland—a son.
CATHIE.—On Sept. 24, at Guildford, the wife of Dr. I. A. B. Cathie—a daughter.
CROSS.—On Sept. 21, in London, the wife of Dr. W. George Cross, of Elstree—a son.
FLOWERDEW.—On Sept. 26, the wife of Dr. F. Digby Mackworth Flowerdew—a son.
GOWAR.—On Sept. 24, in London, the wife of Mr. F. Sambrook Gowar, F.R.C.S.—a daughter.
HINDS.—On Sept. 27, in London, the wife of Dr. S. W. Hinds—a son.
JAMISON.—On Sept. 23, in London, the wife of Dr. Howard M. Jamison—a daughter.
KING.—On Sept. 20, at Clifton, Bristol, the wife of Dr. Charles A. King—a son.
LEIGH.—On Sept. 26, in London, the wife of Dr. A. D. Leigh—a son.
MACKENZIE.—On Sept. 21, in Edinburgh, the wife of Mr. Ian MacKenzie, F.R.C.S.E.—a daughter.
OXLEY.—On Sept. 25, in London, the wife of Lieut.-Colonel W. Malcolm Oxley, R.A.M.C.—a son.
SARSON.—On Sept. 24, at Kettering, the wife of Flight-Lieutenant J. M. G. Sarson, M.B.—a daughter.
SYMONS.—On Sept. 20, at Southborough, the wife of Dr. H. McN. Symons—a son.
THORNTON.—On Sept. 21, at Stratford, the wife of Dr. Kenneth Thornton—a son.

MARRIAGES

GORDON—PEEL.—On Sept. 25, at Guildford, Frederick William Gordon, M.D., to Muriel Peel.
HUNT—CLAPHAM.—On Sept. 10, at Henfield, Geoffrey Notley Hunt, M.R.C.S., to Deborah K. R. Clapham.
SLOPER—CHAPPEL.—On Sept. 21, at Bedford, John Chaplin Sloper, M.R.C.P., to Irene Mary Susan Chappel, M.B.

DEATHS

ADAM.—On August 8, William Caldow Adam, L.R.C.P.E., flying-officer R.A.F.V.R., aged 26.
BASKETT.—On Sept. 25, Bertram George Mortimer Baskett, M.B. Oxfd, of London, S.E.26, aged 84.
JENKINS.—On Sept. 25, at Almondsbury, Glos., Robert Donaldson Jenkins, M.B. Brist., surgeon-commander R.N.V.R.
MACLEOD.—On Sept. 21, Neil Macleod, M.D. Edin., of Horsforth and Leeds, aged 52.
MOORE.—In September, presumed lost when sailing, Joseph Hodgson Moore, M.B. Lond., of Swinton, Manchester, aged 44.
MURIEL.—On Sept. 26, at Norwich, Cecil Jeffery Muriel, M.R.C.S., aged 87.
PHELPS.—On Sept. 29, at Great Malvern, John Henry Dixon Phelps, M.B. Oxfd, aged 74.
UTTING.—On Sept. 22, in Surrey, Ercenwin Anstey Utting, late assistant medical officer of health, St. Pancras.

SYMPATHETIC CONTROL OF BLOOD-VESSELS OF HUMAN SKELETAL MUSCLE*

HENRY BARCROFT
M.D. Camb.
PROFESSOR OF PHYSIOLOGY, QUEEN'S UNIVERSITY OF BELFAST

O. G. EDHOLM
M.B., B.Sc. Lond.
PROFESSOR OF PHYSIOLOGY, ROYAL VETERINARY COLLEGE, LONDON

Vasoconstrictor Tone

THE question whether or not the sympathetic nervous system supplies the blood-vessels in muscle and maintains vasoconstrictor tone during muscular inactivity is of fundamental importance in peripheral vascular disease. Animal investigations on the whole seem to point in that direction. Sympathetic nerve-endings have been identified histologically in the walls of blood-vessels in cat muscle (Hinsey 1928). Increase in blood-flow through muscle in the dog and cat has been observed after section of the sympathetic nerve-supply (Anrep et al. 1934, Baetjer 1930). Nevertheless general opinion, as shown by reviews by Abramson (1944), White and Smithwick (1941), and Wilkins (1942), is against the presence of sympathetic tone in the vessels in human muscle. Recent work in Belfast, however, has convinced us that such tone exists, and we submit here a summary of the evidence in favour of our view.

METHODS

The blood-vessels investigated were those in the muscles of the forearm. Details of the plethysmographic technique have already been published (Barcroft et al. 1943). We wish to emphasise here only the following points:

(1) It is important to maintain the temperature of the forearm as near as possible to its normal physiological level. Lack of this precaution is one of the reasons why the presence of tone in the blood-vessels in human muscle has not been noted by previous observers. During the experiments the limb is kept in a constant-temperature water-bath. Most workers use a water temperature near skin temperature. Grant (1938) used 30° C, most others 32° C. We have measured the temperature and blood-flow in normally clad forearms and find they are maintained at their normal levels when the limb is immersed in water at 34° C (Barcroft and Edholm 1946). Lower water temperatures depress muscle temperature and blood-flow. For example, at 30° C the rate of flow is only about a third of the normal.

(2) We have confirmed Grant and Pearson's (1938) dictum that blood-flow as measured with the forearm plethysmograph is mainly muscle blood-flow. The table shows the approximate distribution of the blood-flow to the different tissues of the forearm in the clothed arm.

EXPERIMENTAL

The proof of the existence of sympathetic tone in the blood-vessels in muscle is summarised below from the paper by Barcroft et al. (1943). Fig. 1 (*a*) shows that the blood-flow in the right forearm is about equal to that in the left. Fig. 1 (*b*) shows that the blood-flow in the left forearm is greatly increased by blocking the median, radial, and ulnar nerves just above the elbow, a technique developed by Dr. W. M. Bonnar. There are the following possible explanations for this vasodilatation:

(1) Release of the sympathetic tone in the vessels of the forearm skin.
(2) Diminution in the resistance opposed to the blood-stream owing to paralysis of tonic contraction of the skeletal muscles.
(3) Release of sympathetic tone in the blood-vessels in the muscles.

Gilding (1932) reviews the published work showing that the sympathetic fibres to skin travel with the cutaneous nerves, whereas those to muscle accompany the motor nerves. The first explanation can therefore be discarded, since the forearm skin is supplied by the antebrachial cutaneous nerves, which are not blocked. The second suggestion can be discarded, because paralysis of the muscles by nerve-block in sympathectomised subjects does not increase forearm blood-flow. Therefore the last suggestion must be correct. The increased blood-flow in the blocked forearm must be due to release of sympathetic tone in the blood-vessels of the muscles. This experiment has been done more than 25 times with consistent results. In the average forearm, blood-flow on the blocked side is about doubled. This means that the muscle blood-flow is increased about 2$^1/_2$ times. If the vasomotor centre were to release the vasoconstrictor tone throughout the skeletal muscles of the body, the blood-flow throughout the muscles would increase by more than a litre a minute.

Some experiments were done under even more strictly controlled conditions. Fig. 2 shows a forearm with adrenaline introduced into the skin by electrophoresis to arrest the cutaneous circulation. By this technique the skin becomes blanched, with occasional small cyanotic patches. The penetration of the adrenaline into the deeper layers was shown by goose-flesh and by paralysis of the sweat-glands. In such forearms the blood-flow was slightly reduced because of the decrease in the amount of blood flowing through the skin. Even so, as fig. 1 (*c*) shows, deep nerve-block increased the blood-flow far above that on the normal side. Obviously the hyperæmia could not have been in the blanched skin and must have been in the underlying muscle. The bone could be safely left out of consideration since its blood-flow is negligible compared with that of muscle (Edholm et al. 1945).

Woollard and Phillips (1932), Friedlander et al. (1938), and Grant and Holling (1938) blocked the sympathetic fibres to muscle and noted that temperature in or over the muscle did not rise. Since blocking the cutaneous nerve-supply to the fingers often causes a very large rise in finger skin temperature, these workers considered that the sympathetic vasomotor tone in muscle must be negligible. However, muscle is less vascular than finger-tip skin; so release of tone would cause far less increase in blood-flow per unit volume of tissue. Moreover in exposed forearms the muscle would be cooling, and release of tone would merely delay the rate of cooling. Further, if the limb had been exposed for some time before the block, muscle blood-flow would be subnormal, and the effect of the block would be reduced. Inferences concerning muscle blood-flow made on the basis of temperature measurements cannot be so reliable as direct plethysmographic determinations.

Warren et al. (1942) measured the forearm blood-flow with the plethysmograph and found that it was increased after paravertebral block. Their suggestion that the increase was entirely in the skin is not borne out by the deep nerve-block and adrenaline electrophoresis experiments described above.

PARTITION OF BLOOD-FLOW THROUGH VARIOUS TISSUES OF FOREARM

—	Muscle	Skin	Bone	Tendon, fascia, &c.
Blood-flow c.cm. per 100 c.cm. of forearm per minute (total flow = 3·1 c.cm.)	2·1	0·8	0·2	
Tissue c.cm. per 100 c.cm. forearm	64·0	8·6	14·0	13·4
Blood-flow c.cm. per 100 c.cm. of tissue per minute ..	3 25	9·7	1·0	0·5

---

* Based on Arris and Gale lectures delivered at the Royal College of Surgeons of England by Professor Barcroft on Dec. 19 and by Professor Edholm on Dec. 20, 1945.

6424

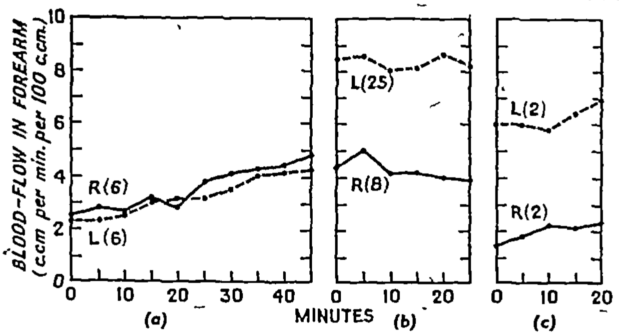

Fig. 1—Blood-flow in forearms: (*a*) right and left arms normal, showing flow equal in both arms; (*b*) deep nerve-block of left radial, median, and ulnar nerves (right arm intact); (*c*) same nerves blocked and cutaneous circulation abolished by adrenaline electrophoresis in left arm (right arm intact). The numerals in parentheses denote the number of experiments from which the averages were obtained on which the curves are based.

To sum up, there is good evidence that the release of sympathetic tone in the blood-vessels in muscle would more than double the rate of blood-flow.

PHYSIOLOGICAL RELEASE OF VASOCONSTRICTOR TONE IN MUSCLE VESSELS BY BODY HEATING

Grant and Holling (1938) found that the blood-flow to the forearm could be increased by heating the legs, but that this required very considerable heat, and the rate of increase varied. They considered that the increase in blood-flow was due to cutaneous vasodilatation. Wilkins and Eichna (1941) also obtained an increased blood-flow in the forearms on body heating, and suggested that some of the increased flow was due to vasodilatation in muscle vessels. We have now carried out this procedure on a large number of subjects with the forearm in water at 34° C, and usually found a considerable increase in the forearm blood-flow when the legs were heated. The effect is absent in sympathectomised subjects. We have also used the skin-blanching technique to analyse the effect, and have shown that the dilatation definitely takes place in the muscle blood-vessels. Fig. 3 shows dilatation in the blanched forearm following immersion of the feet in hot water. Since the increases in forearm blood-flow after deep nerve-block and after feet heating were similar, we concluded that the hyperæmia in the forearm was mainly due to release of vasoconstrictor tone in the blood-vessels of resting muscle.

COMMENT

Grant and Pearson (1938) and Wilkins and Eichna (1941) have shown, and we have confirmed, that forearm blood-flow is practically normal some weeks after sympathectomy. The tone of the blood-vessels in muscle which is released after operation gradually returns. Hence, on theoretical grounds, it does not necessarily follow that sympathectomy could achieve any permanent improvement in peripheral vascular conditions such as intermittent claudication.

Vasodilator Tone

It is now proposed to present some evidence concerning the presence of vasodilator fibres in the blood-vessels of human skeletal muscles.

Vasodilator fibres have been demonstrated by Bülbring and Burn (1937) in muscle vessels in certain animals, notably the hare. Grant and Pearson (1938) and Holling (1939) have shown that adrenaline in small quantities produces vasodilatation in human skeletal muscles. We have confirmed this (Allen et al. 1946) but have found that the dilatation is only fleeting, and, with continued infusion of adrenaline, dilatation is followed by constriction. Nevertheless the fact that a sympathomimetic substance can produce a vasodilatation suggests that adrenergic vasodilator nerves exist.

Grant and Holling (1938) have also presented evidenc of vasodilators in cutaneous blood-vessels, but the conclusions have been criticised by Warren et al. (194

The first experiments we carried out—namely, com parison of the effects of nerve-block and of heating th legs on forearm blood-flow—were inconclusive. A described above, these two procedures produced near similar effects; so it was considered that the increase i blood-flow produced by leg heating was due to release o vasoconstrictor tone alone, not to any active vas dilatation mediated by vasodilator nerves.

More convincing evidence was obtained unexpectedl during an investigation of the effects of hæmorrhage o the peripheral circulation in man, to determine the exten and degree of peripheral vasoconstriction after vene section. In one of the earliest experiments the subjec fainted, and, to our great surprise, the forearm blood flow very much increased during the faint, in spite of th sudden drop in blood-pressure. This unexpected findin made us change the original scheme, and instead a investigation of fainting was initiated (Barcroft et al 1944, Barcroft and Edholm 1945). It was in the cours of this work that evidence was obtained of the existence of vasodilator nerves to muscle blood-vessels.

The large number of blood-donors submitting to venesection has provided opportunities for skilled observation of fainting; so the literature on the subject is now considerable. The incidence of fainting in blood-donors varies, but with a venesection of some 400 c.cm. the average fainting-rate is about 5% (Poles and Boycot 1942, Brown and McCormack 1942). The incidence i affected by fatigue, hunger, and thirst. Posture i important; fainting can and does take place with th subject prone, but is much more easily provoked in th sitting or upright position. *Room temperature* is als a factor. In the Middle East, with a temperature o 100° F or more, the incidence of fainting in blood-donor might be as high as 20% (Buttle 1945). Emotiona factors certainly play a part. It has been a commo experience in blood-donor centres to observe epidemi fainting when many donors are together in view of each other; one donor faints, others follow suit. It has also

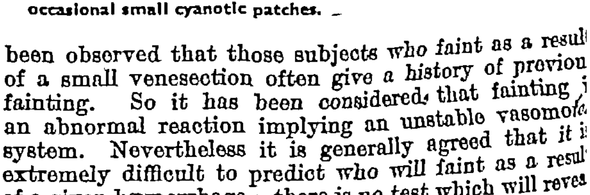

Fig. 2—Forearm, after introduction of adrenaline by electrophoresis int the skin to arrest the cutaneous circulation, showing blanching an occasional small cyanotic patches.

been observed that those subjects who faint as a resul of a small venesection often give a history of previou fainting. So it has been considered that fainting i an abnormal reaction implying an unstable vasomot system. Nevertheless it is generally agreed that it i extremely difficult to predict who will faint as a resul of a given hæmorrhage; there is no test which will reve the potential fainter. However, Wallace and Sharpey Schafer (1941) have shown that the incidence of faintin increases steadily with increase in the volume of bloo withdrawn.

Hæmorrhage is not the only stimulus which wil provoke fainting; emotional shocks, such as the sight o blood, hypodermic or intravenous injection, the uprigh posture, and anoxia, can all be effective. It is a subjec which merits investigation.

Lewis (1932), in a classical paper on the subject emphasised the salient features of a faint: sudden dro in blood-pressure, slowing of the heart, pallor, sweating ommonly nausea, and often loss of consciousness. He showed that the cardiac slowing was not an essential feature of the circulatory collapse, since atropine administered during the faint accelerated the heart without hastening recovery. Lewis epitomised his work by describing fainting as the vasovagal syndrome, meaning that there were two components of the faint, the vagal effects of cardiac slowing, nausea, &c., and a vascular effect. More recently, Barcroft et al. (1944) confirmed that fainting was not a cardiac event. They measured cardiac output with the cardiac catheter, and showed that there was no fall in cardiac output during fainting. Fainting is not a cardiac syncope; it represents a peripheral failure—i.e., the fall in blood-pressure is due to peripheral vasodilatation.

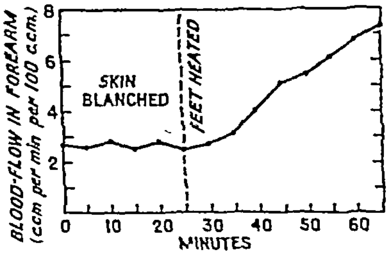

Fig. 3—Effect of leg heating on forearm blood-flow after abolition of cutaneous circulation. Curve based on average of 5 experiments.

In our investigation we used hæmorrhage to produce fainting. We wished to have a high incidence of faints o, as Wallace and Sharpey-Schafer (1941) had shown hat the greater the volume of bleeding the higher the ncidence of faints, we used large venesections. This was done by combining a venesection from the arm with a simulated venesection by inflating pressure cuffs on the thighs to diastolic pressure. Ebert and Stead (1940) have shown that such a procedure dams back up to 700 c.cm. of blood in the lower limbs. It is not unduly uncomfortable, and by releasing the pressure on the thighs the trapped blood is rapidly returned to the general circulation. The average volume of the venesection from the arm was about 500 c.cm., and this, together with pressure on the thighs, produced a faint in nearly every subject. Since our subjects were young healthy adults, this showed that fainting was not an abnormal reaction but one which could be produced by a suitable stimulus in all persons, though the strength of the required stimulus varied from subject to subject. The forearm blood-flow was recorded and the original finding confirmed; the forearm blood-flow increased in every case during the faint.

The next step was to investigate the mechanism of this vasodilatation: was it nervous or humoral? There is evidence that adrenaline secretion is increased during hæmorrhage, and adrenaline has been shown to produce a considerable vasodilatation in the forearm. So there seemed to be a distinct possibility that adrenaline secretion was responsible for this dilatation. To test this hypothesis, fainting was induced in sympathectomised subjects. These patients were rigorously tested to establish that the sympathectomy was still complete. Resting forearm blood-flow was within normal limits, as in all cases the sympathectomy had been performed some time previously. (Grant and others have shown that the forearm blood-flow is only temporarily increased after sympathectomy, the vessels soon recovering their tone.)

In these subjects forearm blood-flow did not increase during fainting; on the contrary, the blood-flow diminished as the blood-pressure fell, and recovered when the pressure rose again. This finding provided definite evidence that the dilatation in normal subjects was not due to the secretion of adrenaline or any other humoral agent, for such effects would still have been present after sympathectomy. On the other hand, since the dilatation was abolished when the vasomotor nerves were absent, it was evident that the dilatation was mediated by the vasomotor nerves.

The next problem was to establish the site of the vasodilatation. A striking feature of the vasovagal syndrome is the intense pallor of the skin, and it seemed very unlikely that the considerable increase in blood-flow could be taking place in the skin vessels. This was investigated by comparing the blood-flow in the hand and forearm. The hand consists largely of skin and bone with only 15% muscle. If the vasovagal dilatation takes place in muscle vessels only, the rate of flow through the hand should diminish during fainting. And that was what we found. Weiss et al. (1937) have previously shown that, during the circulatory collapse induced by amyl nitrite, a collapse which closely resembles the vasovagal reaction, the blood-flow through the hand is unrecordable. However, Rushmer (1944) reported that, in the collapse induced by needling the brachial artery, plethysmograph records of the finger-tip indicated a vasodilatation. Nevertheless in the hand as a whole there is no doubt that the blood-flow decreases during fainting. So it was concluded that, during fainting induced by hæmorrhage, there was a sudden vasodilatation in muscle blood-vessels due to nervous impulses.

This conclusion led to the next question: was the dilatation solely due to the removal of vasoconstrictor tone, or did active vasodilatation occur? Experiments were carried out in subjects in whom a nerve-block was performed in one arm. This procedure, as described above, removes vasoconstrictor tone and therefore increases the rate of forearm blood-flow. When fainting was induced in these subjects, the blood-flow decreased as the blood-pressure fell, behaving similarly to the sympathectomised forearm. But in these subjects the level of blood-flow during the faint was much less than that in the normal arm during the faint. Considering the conditions in the two arms, one with the nerve-block and the other intact, in the first vasoconstrictor tone had already been removed by the nerve-block. If the vasodilatation during the faint was solely due to the removal of vasoconstrictor tone, then the conditions in the two arms during the faint should be the same: in the one arm vasoconstrictor tone removed by nerve-block before the faint, in the other removed by fainting. But the flow in the normal arm at this stage was much greater than in the blocked arm; so this increase could not be solely due to the removal of vasoconstrictor tone, otherwise the level of blood-flow during the faint should be the same in the two arms. During fainting, in brief, there is an increase in forearm blood-flow greater than can be explained solely by the removal of vasoconstrictor tone. It has been shown that no humoral agent is involved and that the skin vessels play no part. The only reasonable conclusion is that part at any rate of this vasodilatation is mediated by vasodilator nerves.

Summary

The technique of demonstrating sympathetic vasoconstrictor tone in blood-vessels in human skeletal muscles is described.

Blood-flow in muscles is more than doubled by the release of sympathetic tone.

Heating the body relaxes the vasoconstrictor tone in blood-vessels supplying muscles.

Vasoconstrictor tone gradually returns to the blood-vessels of sympathectomised subjects.

Vasodilatation takes place in the muscles of the forearm after fainting, except in sympathectomised subjects. Therefore this vasodilatation is due to nervous control.

It is shown that vasodilatation in the forearm muscles is not due merely to removal of vasoconstrictor tone but that it is, at any rate in part, mediated by vasodilator nerves.

PSYCHONEUROSES
TREATED WITH ELECTRICAL CONVULSIONS
THE INTENSIVE METHOD

W. LIDDELL MILLIGAN
M.D., B.Sc. Glasg.
DEPUTY PHYSICIAN-SUPERINTENDENT, ST. JAMES HOSPITAL, PORTSMOUTH

THOUGH there has been some agreement concerning the benefit obtained from electro-convulsive therapy in certain psychoses, recent publications show divergent opinions about its use in the psychoneuroses. Those who believe in its efficacy have so far produced little evidence in support of their statements. Good (1940), Cheney et al. (1941), Zeifert (1941), Furst and Stouffer (1941), Low et al. (1938), and Shapiro and Freeman (1939) report good results in small series of cases, and Feldman et al. (1945) have reported a considerable improvement in 2 cases of acute hysteria. Kerman (1945) mentions only 1 case of psychoneurosis out of 300 various psychotic patients treated by this method, and this patient was only partially improved. Pacella and Barrera (1943) report rather poor results, Smith et al. (1943) state that it is of doubtful value, and Walshe (1945) goes so far as to say that convulsion therapy has no place in the treatment of the psychoneuroses.

This report deals with 100 psychoneurotic patients treated in St. James Hospital, Portsmouth, during the past five years. The intensive method described was originated by Dr. Thomas Beaton, physician-superintendent of this hospital.

METHOD

The apparatus used is a special model manufactured by the Solus Electrical Co. Ltd. All unnecessary recording instruments—*e.g.*, for determination of head resistance—have been eliminated. The maximum voltage is 200, and the time mechanism is calibrated in tenths of a second, increasing by $^1/_5$ sec. intervals to a maximum of 1 sec. It has been found, in treating many patients, that a high voltage can be used with certain advantages and no untoward results. The average dose used has been 180 volts at 0·4 sec. This produces a convulsion in nearly every case and has the further advantage that it eliminates the usual preceding cry. This is very helpful when many patients are being treated in a ward with only movable screens between the beds. No restraint is used, and the only precaution taken, apart from the usual gauze gag, is the use of a dorsal pillow to keep the patient in a position of slight opisthotonos.

The machine, which has a silently acting switch, is moved slowly down the ward on a trolley, and the ward sister manipulates the electrodes while the doctor operates the apparatus. The electrodes are mounted on a flexible metal band of horseshoe shape similar to that used in headphones. This is held momentarily in position on the patient's forehead by means of insulated handles on the outer side of the electrodes. By this method it is possible to treat 20 patients in eight minutes.

We have recently introduced a wireless-set to provide light music during treatment. This is perhaps a minor point, but it helps patients awaiting treatment to pass the time and prevents apprehension while the patient in the next bed is receiving treatment. It also ensures that patients regaining consciousness return to a more cheerful environment.

The number and spacing of treatments vary from case to case. Cook (1944), in a review of convulsion therapy, quotes the average as three a week, and Stockings (1944) refers to the frequency used in some of his own cases—one a day—as drastic. We have employed an intensive method in many cases, particularly in those of long standing. This sometimes involves as many as four treatments a day, the dosage being modified as the patient responds to treatment. The confusion, amnesia, and complete disorientation produced by such treatment call for very careful nursing. In some cases it is necessary to reduce the patient to the infantile level, in which he is completely helpless and doubly incontinent.

The course of treatment is then adjusted so that the patient is allowed gradually to emerge from the confusional state. During this time simple psychotherapy, in the form of explanation and reassurance, is given, and the helpful attitude of the nurses is of the greatest importance. Occupational therapy is used as an adjuvant, and the patient is encouraged to take part in social activities. We are fortunate in that this hospital is situated in the city itself, so that, by a system of gradually extending parole, the patient can slowly resume a normal form of life.

After discharge from hospital the patient usually returns to work immediately and reports at the out-patient department for several months, if necessary. All cases in this series have been followed for a period ranging from eight months to five years.

THEORY OF ACTION

The most satisfactory explanation of the action of electro-convulsion therapy so far advanced is quoted by Brain and Strauss (1945). This postulates the presence of faulty electrical patterns in the brain which are altered by the treatment, the resulting amnesia allowing time for the brain to become accustomed to simplified patterns. If this is so, it is a definite indication for the use of the intensive method, which appears to obliterate entirely the faulty patterns, and thus allows the patient to be rehabilitated along correct lines.

RESULTS

The criteria used in assessing the condition of patients on discharge were as follows :

Patients noted as "*recovered*" were discharged symptom-free and apparently quite stable ; no patient discharged in this category has relapsed.

All patients noted as "*relieved*" were much improved, and most of them were symptom-free, but they were placed in this category if there was any doubt about their stability. Only 6 of the 46 patients in this category have shown any signs of relapse, and 3 of these had received insufficient treatment, having left hospital before the course was completed.

The 2 women noted as "*not improved*" responded treatment at the outset but left hospital before the urse was completed. The male patient included in is category was approaching senility and was precluded om receiving intensive treatment because of his hysical condition.

The numbers discharged in these categories are as llows :

	MALE		FEMALE
Recovered	25	......	27
Relieved	19	......	26
Not improved	1	......	2

hus 51% were classified as "recovered," 46% as relieved," and 3% as "not improved."

The differential classification is as follows :

—	MALE			FEMALE		
	Recovered	Relieved	Not improved	Recovered	Relieved	Not improved
nxiety states ..	10	10	1	8	8	1
ysteria	9	4	..	14	13	1
bsessional states	4	..	..	5	2	..
ixed states ..	2	5	..	..	3	..

ILLUSTRATIVE CASE-RECORDS

CASE 1.—A male married chartered accountant, aged 36, was admitted on April 30, 1945, with four months' history of inability to work owing to a "constant series of figures passing through my mind." He also complained of a severe pain in the throat, preventing him from swallowing properly, and he expressed the fixed idea that this was due to cancer.

Mental State.—An immature type of man, rather childish in manner, very hypochondriacal, anxious, worried, and very apprehensive. He could not speak without first striking his left thigh.

Family History.—Father, aged 56, had died of cancer of the stomach. Mother had died of cerebral hæmorrhage six months ago. She was said to have been a domineering type of woman, on whom the patient had been very dependent, even after his marriage. Her sudden death seems to have been the precipitating factor in the patient's illness. No siblings.

Personal History.—Patient had not had any serious illness. He was said to have worried over details. His school career had been brilliant, and he now held a very responsible position.

Diagnosis.—Obsessive-compulsive neurosis.

Treatment.—April 30, 1945: 3 convulsions induced at 10 A.M., 11 A.M., and 3 P.M.

May 1: 2 convulsions induced at 10 A.M. and 4 P.M.; patient was confused and rather restless, but made no complaints about his throat, and spoke naturally and without his thigh-striking ritual. May 2: 2 convulsions induced at 10 A.M. and 3 P.M. May 3: a convulsion induced at 10 A.M.; patient was confused, amnesic, and completely disoriented. May 5: a convulsion induced at 10 A.M. May 10: he was no longer confused, but there was complete amnesia for events which happened during the week before admission. May 12: a convulsion induced at 10 A.M. May 30: he was well and symptom-free, except for a patchy amnesia, which was slowly clearing.

June 8: improvement had been maintained: patient was discharged "recovered."

July 12: reported in outpatient department (OP); he had remained well and now had a full recollection of events leading up to his admission; he said that he still had slight difficulty in remembering the names of acquaintances.

Sept. 4: reported in OP; he had remained very well and said that he had now no memory difficulties.

Dec. 6: reported in OP; he was completely symptom-free and had no complaints whatsoever.

April 2, 1946: contacted by telephone, he said he had remained perfectly well.

CASE 2.—A male married draughtsman, aged 41, was admitted on March 29, 1945, with fifteen years' history of recurrent attacks of vomiting.

Personal History.—He was said to have been liable to worry unnecessarily since childhood. The attacks of vomiting had been becoming progressively worse; and whereas they had formerly lasted only a few days, with remissions of several months, the present attack had lasted three months, even a glass of water causing him to vomit. In the past ten years he had attended sixteen different doctors, had been admitted to general hospitals four times, for periods varying from two to five months, and in one of these hospitals a laparotomy had been performed. No organic lesion had been found at any time during his illness.

Family History.—Mother, aged 64, said to be nervous and unstable. Father, aged 61, fit and well. Siblings, eight brothers and two sisters, all said to be nervous.

Mental State.—Very hypochondriacal, anxious, worried, and easily upset by trifling incidents, manifesting this by acute attacks of anxiety. He realised that these acute attacks were responsible for his gastric upset.

Diagnosis.—Chronic anxiety state.

Treatment.—March 30, 1945: 3 convulsions induced at 10 A.M., 12 noon, and 2 P.M. At 4 P.M. patient was only slightly confused. March 31: 4 convulsions induced at 10 A.M., 12 noon, 2 P.M., and 4 P.M.; at 6 P.M. patient was confused, amnesic, and disoriented in time.

April 1: 3 convulsions induced at 10 A.M., 2 P.M., and 5 P.M.; patient was now very confused and completely disoriented, tended to be restless, and required careful supervision. April 2: a convulsion induced at 10 A.M. April 6: a convulsion induced at 10 A.M.; patient was now only slightly confused, was bright and cheerful, had no complaints, and enjoyed full hospital diet. April 8 and 10: a convulsion induced at 10 A.M. each day. April 16: he was now bright and cheerful, coöperative, and symptom-free; he said he enjoyed his food for the first time in fourteen years and could eat anything; his interests were varied, and he was doing some fairly heavy manual labour in the villa garden. April 26: he remained well and, though he was occasionally upset, the resulting anxiety reaction was much less severe than formerly. April 28 and 30: a convulsion induced at 10 A.M. each day.

May 17: he remained well and symptom-free. May 20: discharged "recovered."

June 21: attended OP; had remained well, had started work, and reported no difficulties.

Sept. 6: attended OP; was very well and said he could eat anything and had gained 2 st. in weight during the past three months.

Dec. 20: attended OP: he had remained well.

Feb. 21, 1946: attended OP; he said he felt perfectly fit and had no complaints; he had gained self-confidence and was apparently stable.

April 11: reported at OP; had remained perfectly well.

CASE 3.—An unemployed single man, aged 51, was admitted on Sept. 1, 1945, with twenty years' history of epigastric pain and ten years' history of inability to swallow solids.

Personal History.—No illness or accident until the age of 22, when he was badly wounded while serving in an infantry regiment during the war 1914–18. He had been in hospital eighteen months and had subsequently had many operations for the removal of shrapnel. He had been employed as a stage hand from 1921 to 1926, but since then had done no work, lived on his disability pension, and had been a chronic invalid. He had been admitted to five general hospitals for investigation, and laparotomy had been performed twice. No organic lesion had ever been found. For the past ten years he had been existing on a diet composed solely of three pints of milk a day, with an occasional raw egg.

Family History.—Parents had died of natural causes, and little information was available about them. He had one brother and four sisters alive and well. These relations lived in widely separated parts of the country and had on many occasions received telegrams summoning them to patient's bedside. On each occasion the message has been dictated by patient, who said he was dying.

Mental State.—Egocentric, petulant, and plausible, and delighted in giving a long circumstantial account of his illness, going into unnecessary details. He showed no trace of depression, though he complained bitterly of his treatment in other hospitals and said that no doctor had ever properly understood his case.

Diagnosis.—Hysteria.

Treatment.—Sept. 2, 1945: 3 convulsions induced at 10 A.M., 12 noon, and 4 P.M. Sept. 3: 2 convulsions induced at 10 A.M. and 2 P.M. Sept. 4: 2 convulsions induced at 12 noon and 3 P.M.; he was very confused, completely disoriented, and restless, and his habits had become faulty. Sept. 5, 6, and 8: a convulsion induced at 10 A.M. each day. Sept. 10: he was less confused but tended to be very elated. Sept. 12: a convulsion induced at 10 A.M. Sept. 16: he was bright, cheerful, and contented, and had no complaints.

Oct. 3: he was quite settled, worked well in the villa garden, and had, for the past fortnight, enjoyed full hospital diet; he ate his food with great relish; there was no trace of either confusion or amnesia.

Oct. 9: he was discharged "recovered." Oct. 23: reported in OP; he had remained well and had no complaints.

Nov. 20: reported in OP; he had remained well and was apparently stable.

March 28, 1946: reported in OP; he had remained very well and said he could eat anything and hoped to find employment in the near future.

CASE 4.—A married male bus conductor, aged 48, was admitted on Nov. 2, 1945, with three years' history of severe pain in the back, preventing work.

Personal History.—Had been healthy and had a good work record until 1941, when he had received severe burns of the lower limbs in a motor accident. He had spent nine months in a general hospital and been unable to resume employment until November, 1942.

Three years ago, while employed as a bus conductor, he had accidentally fallen down the stairs of his omnibus. He had complained of pain in the back, but had been able to continue work. He had consulted his doctor, who had treated him for a month; but, as the pain had still persisted, he had been referred to the OP of a general hospital. There it had been thought that he had a tuberculous lesion of the spine, and he had spent the next two months in a sanatorium. He had then been referred to an orthopædic surgeon, who had recommended massage and radiant heat, as no bony injury had been found on radiography. As there had been apparently no alteration in either the nature or the severity of the pain, he had been fitted with a plaster-of-paris spinal jacket. Two months later he had been admitted to an E.M.S. hospital, where for three months he had been investigated and treated. He had again been fitted with a spinal jacket and discharged from hospital.

For three years he had been receiving £5 a week compensation.

Family History.—He was one of a family of fourteen. One brother had died of pulmonary tuberculosis.

Mental State.—Though he said he was very worried and depressed because of his inability to work, there was no trace of this at the interview, when he was quite cheerful. He walked in a most peculiar manner, with the aid of two walking-sticks. He gave a reasonable account of himself and said he was most anxious to resume his employment.

Diagnosis.—Hysteria.

Treatment.—Nov. 3, 1945: 4 convulsions induced at 10 A.M., 12 noon, 4 P.M., and 6 P.M. Nov. 4: 3 convulsions induced at 10 A.M., 2 P.M., and 4 P.M.; patient was very confused, constantly asked why he was in hospital, and said there was nothing wrong with him. He walked in a fairly natural manner. Nov. 5 and 6: a convulsion induced at 10 A.M. each day. Nov. 8: he was much less confused, but did not remember why he was admitted. Nov. 9, 12, and 14: a convulsion induced at 10 A.M. each day. Nov. 15: he was now rather elated, but had no complaints and was walking normally.

Dec. 20: He remained very well and was much more settled; he now fully appreciated the reason for his admission. Dec. 25: he was bright, cheerful, and symptom-free, and was assisting the gardener; he had been demonstrating his physical capabilities to his fellow-patients by man-handling a heavy garden roller single-handed.

Jan. 2, 1946: discharged "recovered."

Feb. 14: reported in OP; he had remained well and had resumed work.

April 9: reported in OP; he said he felt very well, was completely symptom-free, and was finding no difficulties in connexion with his employment.

CASE 5.—A married housewife (ex-school teacher), aged 43, was admitted on Jan. 16, 1944, with fifteen years' history of a constant feeling of faintness; inability to walk more than a few steps without collapsing; inability to write or knit, owing to weakness of hands; and inability to sleep.

Personal History.—She had been fairly well until the birth of her son, fifteen years ago. Since then she had adopted the rôle of a permanent invalid, had been very jealous and possessive, and constantly demanded the complete attention of her husband and son. She said she had no friends.

Family History.—Mother had died of cancer at 65. She was said to have been a dominating type of woman, who never allowed the patient to do anything for herself. Father had died of cancer at 62. No siblings.

Mental State.—She was very miserable, self-pitying, and petulant, and could talk of nothing but her various symptoms. She constantly demanded attention and, if this was not forthcoming immediately, wept copiously and called out for her husband and "baby." Her conversation was carried on in an exhausted whisper, but she could raise her voice considerably when she wanted anything.

Diagnosis.—Hysteria.

Treatment.—Jan. 17, 1944: 2 convulsions induced at 10 A.M. and 12 noon. Jan. 18: 2 convulsions induced at 12 noon and 4 P.M. Jan. 19: 2 convulsions induced at 10 A.M. and 3 P.M.; she was still miserable and emotional but was sleeping well without sedatives. Jan. 20: 2 convulsions induced at 10 A.M. and 4 P.M.; she was becoming more confused but was now very hostile. Jan. 21: 2 convulsions induced at 10 A.M. and 12 noon; she was very confused, disoriented, and very restless. Jan. 22 and 23: a convulsion induced at 10 A.M. each day. Jan. 27: a convulsion induced at 10 A.M.; she was now bright and cheerful and had no complaints, though she was still confused.

Feb. 2 and 6: a convulsion induced at 10 A.M. each day. Feb. 15: she was very much improved, bright, cheerful, and coöperative, attended the occupational therapy department daily, and mixed well with other patients; she now said her husband had always spoiled her, and that it would "do her good" to have another child.

March 23: improvement maintained; she was cheerful and energetic; she attended all functions and was especially keen to be present at the dances. March 30: discharged "recovered."

April 18: reported in OP; she had remained well and was doing all her own housework for the first time in seventeen years.

June 7, 1945: reported in OP; she had remained very well, and her husband said she was a "changed woman."

March 22, 1946: social worker visited patient in her home and reported that she was perfectly well; bright and sociable, and had made many friends in the neighbourhood.

CASE 6.—A single female cashier, aged 25, was admitted on Jan. 3, 1945, with two years' history of breathlessness, palpitation of heart, frontal headache, and a constant feeling of tension.

Personal History.—She had been perfectly fit until three years ago, when she had had an attack of rheumatic fever. She had been told that her heart might be affected, and since then she had been very easily upset.

Family History.—Mother had died of cancer at 53. Father, aged 63, had "heart trouble." She had two brothers. A sister had died of "heart trouble."

Mental State.—She was very anxious, worried, apprehensive, dissatisfied with life, and very hypochondriacal. Her father had remarried two years ago, and she expressed great resentment at this, becoming rather excited and emotional when discussing it. She was very miserable and said she did not like being an invalid.

Diagnosis.—Anxiety state.

Treatment.—Jan. 24, 1945: she had been treated on general lines; but, though slightly brighter, she was still very unstable and complained of her cardiac condition. There was no physical lesion to explain her breathlessness and tachycardia, which were undoubtedly anxiety manifestations.

Feb. 3: 2 convulsions induced at 10 A.M. and 5 P.M. Feb. 4 and 5: 2 convulsions induced at 10 A.M. and 2 P.M. each day. Feb. 6–10: a convulsion induced at 10 A.M. each day. Feb. 14: a convulsion induced at 10 A.M.; she was confused and rather restless, but was now elated and made no complaints. Feb. 16: a convulsion induced at 10 A.M. Feb. 28: she was still slightly confused and amnesic but more settled and was sleeping well.

March 10: she was bright, cheerful, coöperative, and symptom-free, attended the occupational therapy department daily, enjoyed walking, and took part in all social activities.

March 28: discharged "recovered."

April 19: reported in OP; she had remained well and was anxious to start work.

July 5: reported in OP; she said she was very well and had been working as a cashier for the past two months and had no difficulty in carrying out her duties.

Nov. 22: visited by social worker, who said that she had remained well and could take part in all normal social activities.

March 21, 1946: reported in OP; she had remained very well.

Case 7 is included to illustrate the necessity of giving a thorough course of treatment to every patient. In this case treatment was suspended owing to an unfortunate accident, and the patient left hospital against advice. She remained well for three months but subsequently relapsed. She was recently readmitted and is now receiving a complete course of treatment.

CASE 7.—A single woman, aged 52, of no occupation, was admitted on Oct. 7, 1945, with two years' history of overwhelming fear that she would do some "terrible thing" if she did not wear a particular pair of gloves.

Personal History.—She had always been very healthy and had led an active life in the country. About two years ago she had had an inconclusive love affair (her only one), and this had left her with a strong feeling of guilt. Since then there had been a gradual development of obsessional ideas and ritual, which now dominated her completely.

Family History.—Father, a country gentleman of high intellectual attainments, had died of cerebral hæmorrhage 10 years ago. Mother an overanxious type, on whom the patient depended completely and who treated the patient as a child. Mother and daughter had been living alone for the past three years and were inseparable. No siblings.

Mental State.—She was very restless, apprehensive in the extreme, and agitated, and continually asked that her hands should be tied together in case she should harm anyone. She said she was terrified lest she should be left alone for even a minute.

Diagnosis.—Obsessional state.

Treatment.—Oct. 7, 1945: 3 convulsions induced at 11 A.M., 12 noon, and 5 P.M. Oct. 8: 2 convulsions induced at 10 A.M. and 4 P.M.: patient was very restless and confused, and constantly asked where she was. Oct. 9: patient accidentally fell out of bed and sustained an injury to the left side of the face: radiography revealed no bony injury; but, as she complained of severe pain on opening the mouth, electrical treatment was suspended for the time being. Oct 12: she was still slightly confused but bright and cheerful, having forgotten her obsessional ideas.

Nov. 7: she remained fairly well and said she remembered her previous obsessions but now laughed at them; she refused to remain in hospital for further treatment as she was worried about her mother. Nov. 12: discharged at her own request, contrary to medical advice, "relieved"; she was cheerful, had no complaints, and no memory difficulties, and was relatively stable, but it is unlikely that she will remain so in view of the curtailed course of treatment.

Feb. 6, 1946: patient telephoned to report that she remained well.

March 2: patient telephoned to report that she had been very worried about her mother's health during the past fortnight; she had lost a good deal of sleep and was again afraid that she might injure someone. March 10: readmitted to hospital; her mental condition was similar to that on her first admission.

DISCUSSION

These results seem to indicate that electro-convulsive therapy, particularly the intensive method, is of the greatest value in the treatment of selected cases of psychoneuroses. Though this is a physical method of treatment, it is of the utmost importance to adopt sound psychological principles in the rehabilitation and remoulding of the patient's personality during the recovery period. Mere obliteration of psychologically unacceptable patterns of thought and conduct is not sufficient, and the resynthesis of the personality requires much care and judgment.

In the present series the main factor militating against successful treatment has been an inherent constitutional defect, which may range from slight immaturity to definite high-grade mental deficiency. As might be expected, approaching senility is another factor of unfavourable prognostic import.

The anxiety states, on the whole, respond well, especially those of long duration. Cases of conversion hysteria do very well and, more important still, do not tend to relapse, if thorough treatment has been carried out. Striking results are obtained in obsessional states, which do not respond to other methods of treatment, except prefrontal leucotomy. It is admitted that, except in four cases, the follow-up has not been long enough to permit of dogmatic statements regarding the benefits of electro-convulsive therapy over the latter procedure, but the advantages are, nevertheless, apparent. There is practically no danger attached to the use of electro-convulsive therapy, and in our opinion no patient should be subjected to prefrontal leucotomy before a complete intensive course of electrically induced convulsions has failed to produce the desired effect.

In the light of experience it has been the custom of this hospital, during the past year, to use electro-convulsive therapy on inpatients only. It was found that outpatients returning to their home environment after each treatment did not respond satisfactorily. In using the intensive method it is essential to have the patient in hospital, and in view of the gross confusion, restlessness, and, especially in hysterics, the occasional outbursts of impulsive behaviour, this treatment should only be carried out in a mental hospital, where there are adequate facilities for dealing with disordered behaviour. The mental hospital has the added advantage that it usually possesses extensive grounds, and this is of great importance to the convalescent patient.

The use of electro-convulsive therapy greatly shortens the duration of psychoneurotic illness; and, especially in chronic cases, it seems to be of much more value to admit the patient to hospital for a month or six weeks rather than to compel attendance at an outpatient department for many months or even years. Many psychoneurotics are notoriously lacking in patience with regard to their treatment and become very bored with hospital life. The use of electro-convulsive therapy prevents this completely and tides the patient over the initial period of readjustment to hospital routine. It is just this adaptation that the psychoneurotic often finds impossible because of his general maladjustment to environment. It is not, however, suggested that this treatment should be used merely as a short cut—on the contrary, great care should be exercised in the selection of cases. In this hospital only a relatively small proportion of psychoneurotics have been treated by this method. In most of these cases the symptoms were of long duration and the more recent cases had proved resistant to psychotherapeutic measures.

None of these cases has exhibited the prolonged memory defects noted by Brody (1944), and in this connexion it seems that his statement about the contra-indications to the use of this form of therapy is, to say the least, dogmatic. This series included several school-teachers, a chartered accountant, the department manager of a large business, a bus conductor, and a cashier. It would have been grossly unfair to debar these patients from treatment on the grounds of occupation alone. A patient (not included in this series), who was treated by intensive electro-convulsive therapy, is employed in a Government department as a linguist and reports that she has no memory difficulties but continues to express herself freely in five languages.

SUMMARY

The results of electro-convulsive therapy in 100 cases of psychoneuroses are summarised.

An intensive method was used in many cases, up to four convulsions being induced daily. This procedure is especially suitable for chronic cases.

All cases responded well, but the most striking results were noted in those of long duration.

Electro-convulsive therapy should not be used indiscriminately; the greatest care should be taken in selecting cases.

The course of treatment for each patient should be based on the original clinical findings and modified according to the response produced.

I wish to thank Dr. Thomas Beaton, physician-superintendent of this hospital, for helpful criticism and for permission to use the case material; and Dr. Elizabeth Barker, senior assistant physician of the hospital, for help in connexion with the female case-records.

EFFECT OF TEMPERATURE ON SEDIMENTATION-RATE

K. B. Rogers
M.B. Lond.

LATELY PATHOLOGIST, SHOTLEY BRIDGE EMERGENCY HOSPITAL, CO. DURHAM

The effect of temperature on the erythrocyte-sedimentation rate has been noted by workers using all the different techniques that are known. Westergren (1921) suggested a correction for it, especially if cases were to be followed up, but he stated that the difference in temperature in the average laboratory was not great. Nichols (1942) states that any technique is valueless if the results are not comparable on repetition, and he notes the importance of a constant temperature if the results are to be reproducible. It was through trying to obtain reproducible results that the following work was performed; there is a regional chest centre based on this hospital, and some cases have to be tested many times.

The standard E.M.S. issue is the Westergren apparatus. With the stand supplied, if one of the six tubes was fixed vertically with its lower end in the centre of the rubber pad at the base, it was found that, if the other five tubes were also to be vertical, their lower ends were scattered round the periphery of their respective pads, and none of them would occupy the same relative position; this wasted a great deal of time when the tubes were set up. Also, it became obvious that the Westergren technique would not allow for the changes in corpuscular volume, such as resulted if a patient had had much blood-loss or a transfusion before operation.

ANALYSIS OF 736 CASES USED IN TESTING SEDIMENTATION-RATE

Chest investigation	No. of cases	Medical wards	No. of cases	Surgical wards	No. of cases
Carcinoma of œsophagus	6	Psychoneurosis	75	Carcinomata	23
Carcinoma of bronchus	27	Peptic ulceration	24	Osteomyelitis	7
Mediastinal Hodgkin's disease	7	Diarrhœa	15	Postoperative sepsis	21
Cardiovascular lesions	12	Infective hepatitis	4		
Lung abscess	17	Malaria	29		
Empyema	50	Urinary infections	13		
Bronchiectasis	55	Blood diseases	29		
Bronchitis	72	Rheumatism and chorea	62		
Pulmonary tuberculosis	142	Arthritis and spondylitis	40		
Pick's disease	6				
Total ..	394		291		51

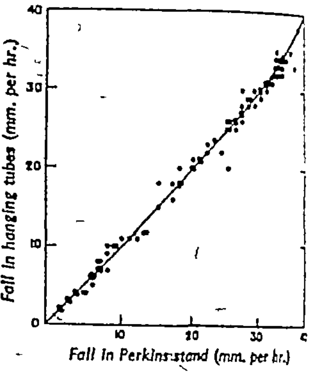

Fig. 1—Comparison of readings at 20° C in the Perkins stand and in hanging tubes, showing very little difference.

A change was therefore made to the Wintrobe technique, using the Perkins stand and the correction graph of Hynes and Whitby (1938). The results were still not reproducible, and the variant factor was temperature. The laboratory is a single-storied building placed on an exposed hillside, and the temperature could vary 7° C in a day, and more than 15° C between winter and summer. Mere statement that the test was performed in a certain season gives no indication of the average temperature: four inches of snow appeared in a recent May.

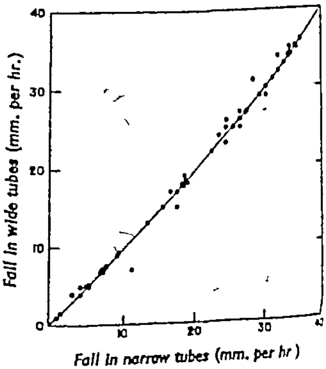

Fig. 2—Comparison of readings at 20° C in tubes 3·5 mm. in diameter (Rourke and Ernstene 1930) and in tubes 2·5–2·8 mm. in diameter (Wintrobe), showing very little difference.

TECHNIQUE

To perform the following experiments an apparatus had to be devised that would allow the sedimentation tubes to be kept at controlled temperatures. A holder was designed to slip over the top of the tube and allow it to hang as its own plumb-line (Rogers 1946). The tubes were suspended in water contained in a glass 7-lb. sweet jar by passing them through a perforated cardboard lid; one set of tubes was kept at a standard temperature of 20° C and the other at the test temperature. (A tube stops swinging within a few seconds when suspended in water.)

The temperature was maintained to within 1° C; thus, if there was to be a mean temperature of 10° C, the water was placed at 9·5° C; when it was warmed to 10·5° C, the lid was lifted off the jar, and the tubes were transferred to another sweet-jar with water at 9·5° C. This would necessitate about two changes of water when there was 10° C difference between the external room and the test temperature.

The material used consisted of blood from routine examinations, mostly from chest cases. The bloods were all drawn by me, using no. 20 hypodermic needles, oil-sterilised syringes, and no tourniquet; 2 c.cm. of blood was placed in a tube containing the correct amount of Heller and Paul's mixture or heparin. Up to six different bloods were put up for the test, $^1/_2$–2 hours after collection; the bloods were thoroughly mixed, and a set of tubes was filled at $^1/_2$-min. intervals and placed at 20° C; the same bloods were remixed and then placed into duplicate tubes at the test temperature.

There was, therefore, in each point plotted a strict comparison between the same blood, in the same anti-

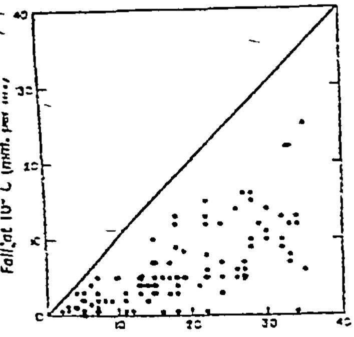

Fig. 3—Comparison of readings at 20° C and 10° C.

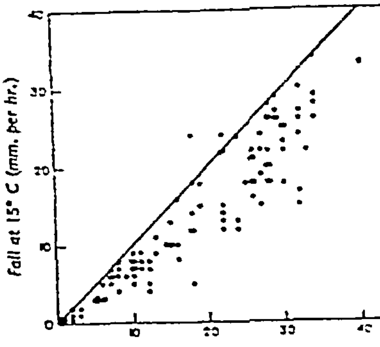

Fig. 4—Comparison of readings at 20° C and 15° C.

coagulant put up in a similar tube but at a different temperature. The fall was recorded an hour after each blood was put up; comparisons were made between the orrected rates, after the bloods had been centrifuged nd corrected by Hyne and Whitby's graph.

Weingarten (1945), using Westergren's technique, has hown that the accelerating effect of high temperature is not constant; that, when liver damage is well marked, a sedimentation-rate test performed at 3·5° C will give a higher reading than will a duplicate test at 38° C. An analysis of the cases used in this investigation is given in the accompanying table. None of the cases would be likely to fit into Weingarten's group III; they would all seem to be in his group I, which is probably the same for most cases in any English hospital.

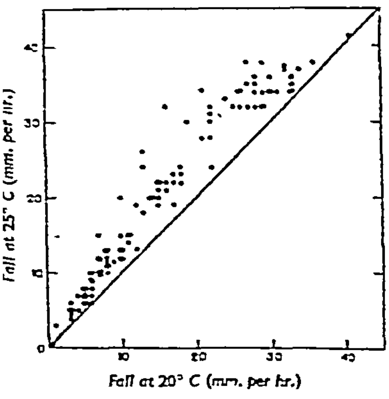

Fig. 5—Comparison of readings at 20° C and 25° C.

RESULTS

Figs. 1–7 show the patterns obtained; they record the results of just over 100 experiments at each temperature. No graphs have been drawn, as it is not desirable that corrections should be attempted; but it would be more useful if a standard temperature was always used. Figs. 3–7 show the effect of varying the temperatures at which the tests are done. The differences are most marked in the middle range; for example, a "slight" could become a "moderate" increase in rate, if the temperature were 5° C higher (20°–25° C). The 10° C chart shows that this temperature provides results that are too scattered, at all increases in rate, to be trustworthy.

TIME TAKEN FOR BLOOD TO REACH TEMPERATURE OF SURROUNDING WATER

A micro-ammeter was connected to a thermocouple kept in an ice-water mixture at 0° C; another thermocouple, in series, was first placed in water at 22° C, then at 32° C, and readings were taken on the ammeter for the purpose of calibration. A Wintrobe tube, with a thermocouple placed down the centre, was filled with blood and suspended in water at 32° C; it was then transferred to water at 22° C, and the time that the ammeter took to equilibrate to the 22° C reading was noted. The experiment was repeated with the tube transferred back to the water at 32° C. The thin type (Baird and Tatlock) Wintrobe tube took an average of 52½ sec. and the thicker (Hawksley) glass Wintrobe tube took 67½ sec. to attain an equilibrium. (It was realised that the type of curve was really asymptotic, but the results are sufficiently accurate for this type of work.) Each result is the average of four experiments.

CONCLUSION

It seems that the experiment of Wintrobe and Landsberg (1935), from which they concluded that there was no significant effect of temperature betwen 22° C and 27° C, gave a wrong impression, and that a rise from 22° C to 27° C has very appreciable effects. In their paper giving a correction graph for varying corpuscular volumes Hynes and Whitby (1938) do not mention the temperature, but Whitby and Britton tell me that this work was carried out in winter, without temperature being recorded or controlled. From the above results it appears that their average temperature was probably about 18° C; this is at variance with Whitby and Britton (1944) who suggest performing the tests at temperatures between 22° C and 27° C; this range is both too high and too wide.

The ranges of temperature experienced in this laboratory are probably very similar to those in sanatoria, and it is desirable that the temperature at which the tests are carried out may be controlled in the future. Often a test is set up in the ward, which is well ventilated; hence in winter the temperature will be very near 10° C, a temperature at which results are untrustworthy. This will explain the results quoted by Edwards and Cuttrill (1942) who urge the use of a standard temperature.

SUMMARY

A method has been devised of keeping sedimentation tubes at a controlled temperature by suspending them in a container of water. The use of only one constant temperature is desirable.

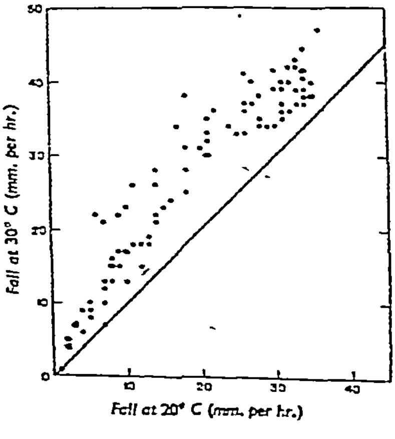

Fig. 6—Comparison of readings at 20° C and 30° C.

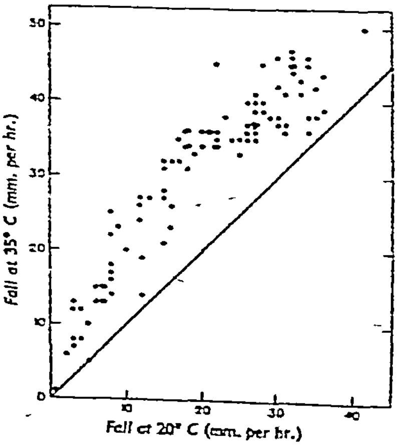

Fig. 7—Comparison of readings at 20° C and 35° C.

In the cases investigated (in England) variation in temperature affected the sedimentation-rate, increased rates being recorded with rises in temperature. Temperatures below 15° C should never be used.

I wish to thank Mr. E. W. Switzer, of Shotley Bridge, who produced the original holders; Messrs. Willen Bros. Ltd., for making the holders; Sir Lionel Whitby and Dr. C. J. C. Britton for help and advice; my colleagues in this hospital for their coöperation; and Mr. L. B. Holt, who supplied the apparatus and advised in the experiments using the microammeter.

TREATMENT OF YAWS WITH PENICILLIN

K. R. Hill

LATE CONSULTING PHYSICIAN, WEST AFRICAN COMMAND

A. Macpherson
M.B. Edin.
MEDICAL OFFICER, WEST AFRICAN MEDICAL STAFF

The original observations of Mahoney et al. (1943) on the curative action of penicillin in syphilis have now received ample confirmation. Comparatively few investigations, however, have been made on the action of penicillin in yaws.

In a preliminary communication from West Africa, Findlay et al. (1944) recorded results obtained with penicillin in 24 cases of primary and secondary yaws. Whitehill and Austrian (1944) reported the successful treatment of 17 cases in Fiji, da Cunha et al. (1944a and b) 12 cases in Brazil, and Logfren (1944) 1 case in a European. These observations showed that *Spirochæta pertenue* is highly susceptible to penicillin; the period of observation, however, was in all cases short.

In the present communication, in addition to the 24 cases originally described (Findlay et al. 1944), of which 20 were followed for considerable periods, 104 further cases are discussed. The patients were all African children or mothers belonging to various tribes.

TECHNIQUE OF ADMINISTRATION

Both sodium and calcium salts were used intramuscularly. With 20,000 units dissolved in saline and injected every three hours for twelve- to twenty-four hours, the primary and secondary lesions rapidly disappeared. Continued observation showed, however, that after two to three months some cases relapsed, as had been noted in syphilitics by Mahoney et al. (1944). A total dosage of 1,000,000–1,500,000 units thus seemed indicated, but a course of three-hourly injections for six or seven days was impossible with African children.

On the appearance of the paper by Romansky and Rittman (1944), suggesting the suspension of penicillin in ground-nut (pea-nut) oil with beeswax, this technique was adopted: 5 c.cm. of sterilised 2% beeswax in ground-nut oil is added to the solid penicillin in the phial, and the mixture is shaken with glass beads for an hour. Despite great care the resulting suspension, at any rate in the tropics, was lumpy. It had to be injected through a wide-bore needle, and the injection caused extreme pain. A second method was therefore tried. The dried penicillin was first dissolved in 1 c.cm. of sterile physiological saline; then 4 c.cm. of sterile beeswax in ground-nut oil was added. On shaking immediately before administration a fine emulsion was produced. One daily injection of 100,000 units was given intramuscularly. This was well tolerated and caused little pain.

CONCENTRATION OF PENICILLIN IN BLOOD AND URINE

Tests on the concentration of penicillin in blood and urine, when penicillin was given by the above two methods, were made both by the slide-cell technique and by the capillary-tube method described by Fleming (1944).

The administration of 100,000 units every twelve hours in beeswax and oil suspension gave a persistent blood concentration of 0·1–0·15 unit, and urine concentrations of 60 units per c.cm. throughout the twenty-four hours. When the same dose was given in an emulsion of saline with oil and beeswax, the blood and urine concentrations were of the same order and only more sustained by two or three hours than those obtained when penicillin was given in saline alone (cf. Fleming et al. 1944).

TIME OF DISAPPEARANCE OF SPIROCHÆTES

In 6 cases of secondary yaws in children, serum from lesions was examined for spirochætes by dark-field illumination. Results are shown in table I. Spirochætes were no longer visible in the lesions nine to twenty-four hours after the start of treatment. Logfren (1944), in his case of yaws in an adult European, found that the spirochætes had disappeared eighteen hours after treatment; Whitehill and Austrian (1944) found them absent after sixteen hours in 16 cases, and forty hours in 1 case.

RESULTS OF TREATMENT

There appeared to be little difference between the clinical results obtained with sodium penicillin and with calcium penicillin; nor, despite the low blood and urine concentrations obtained with the saline and ground-nut oil suspension, did the results appear inferior to those obtained with penicillin in saline alone or in oil suspensions.

The only serious reaction was an abscess in the buttock of one small boy; the pus contained penicillin but yielded a pure growth of *Ps. pyocyanea.* No Herxheimer reactions were observed, though in syphilitics treated with penicillin Mahoney et al. (1944) and Moore et al. (1944) encountered them in 86% and 59% respectively. It must be remembered, however, that African children so constantly have attacks of malaria that they make little of a temperature which would at once send a European to bed.

TABLE I—DISAPPEARANCE OF SPIROCHÆTES

Case	Time of disappearance after treatment (hr.)	Dose of penicillin* (units) up to time of disappearance	Total penicillin* (units) used to complete treatment
18	9	75,000	100,000
19	9	50,000	50,000
21	9	75,000	120,000
58	24	200,000	1,200,000
75	9	100,000	1,300,000
110	24	200,000	1,200,000

* In saline

Primary Cases.—We treated 15 cases of primary yaws; dosage varied from 100,000 to 1,500,000 units. There were 2 failures, though 1 of these cases showed slight improvement in four months. The average time for a clinical cure—that is, the disappearance of the mother yaw—was nine days. Within twenty-four hours there was drying up of the yaw and flattening of the verrucous base, or, in cases where a scab had already formed, pronounced desiccation; within forty-eight hours commencing epithelisation was apparent or desquamation of the scab; in three to six days healing t the lesion was well advanced; by about the ninth ay the site of the lesion was denoted by a grey-brown r pink scar, or, in the case of a thick keratinised surface ike the sole of the foot, by complete restitution of ormal tissue.

Of these 15 cases, 6 were followed up: 4 showed sustained cures, 1 at four months, 1 at five months, and 2 at seven months; 1 case had relapsed at three months but again responded to further treatment and had no relapse five months later; and 1 case, which had appeared to be an immediate clinical failure, was found to be cured when seen eight months later.

In 5 cases the Kahn reaction was reversed; in 2 after one or two weeks, in 1 within four months, and in 2 within seven months of treatment. The first 2 cases had only two or three weeks' history of yaws; the dosage of penicillin was 100,000 units. The other 3 cases were of six weeks' to three months' standing; and, though the Kahn reaction was not reversed three months after treatment, it later became reversed. In 1 case, which had four days' history of yaws and a negative Kahn, there was an immediate clinical cure, which was sustained after a month's follow-up, the Kahn reaction being still negative.

TABLE II—FOLLOW-UP RESULTS IN SECONDARY YAWS

Period of observation (months)	No. surveyed	No. of sustained cures	No. of relapses during this period
1½–3	63	61	2
4 – 6	45	44	1
7 –12	21	21	..

A typical primary case treated with penicillin was as follows.

CASE 1.—A girl, aged 2 years, had two weeks' history of a large primary yaw on the left heel, consisting of an ulcer 1 cm. in diameter, with a fungoid granulomatous base. Kahn and Ide tests both negative. Penicillin sodium, 100,000 units, in beeswax and oil, injected into buttock.

Within twenty-four hours there was drying up of the ulcer and flattening of the verrucous base; at forty-eight hours epithelisation was apparent; and at seventy-two hours healing of the ulcer was well in progress. At six days the lesion was healed, leaving pink scar tissue. A month later cure was found to be sustained. No relapse. Kahn and Ide both negative. No further follow-up.

Secondary Cases.—We treated 96 secondary cases; 81 completed the course, and 78 of these showed immediate clinical cure. The result in 15 cases was uncertain, because immediately after the course of treatment the patients ceased to attend and left the district.

The average time for clinical cure was eight and a half days. The papules desquamated, and the typical yaw scabs dried up and lost their yellow colour within twenty-four hours. Between two and ten days the scabs underwent further desiccation and flaked off, leaving white, pink, or greyish-brown scar tissue at the site of the original lesion.

Table II gives the results of a clinical follow-up over a period up to a year of cases which were originally "immediate clinical cures": 63 cases were followed up to three months, 45 up to six months, and 21 up to twelve months.

On relapse, yaws lesions in new situations were commonly encountered, but also there was often a breaking down at an old site to form a shallow ulcer, which sometimes had a very mixed flora, including on occasions spirochætes and fusiform bacilli; such lesions may therefore have been ordinary tropical ulcers.

Table III gives the results of a serological follow-up over a period up to one year. This survey shows 7 cases with reversal of Kahn out of 40 cases examined, up to a year from the date of treatment.

TABLE III—SEROLOGICAL FOLLOW-UP RESULTS IN SECONDARY YAWS

Period of observation (months)	No. of cases examined	No. of cases with reversal of Kahn	No. of cases with positive Kahn
1½– 3	40	1	39
4 – 6	31*	4	27
7 – 9	19	2	17
10 –12	8	..	8

* Includes one case that had a reversed Kahn reaction at 4 months but a serological relapse at 5 months, though still maintaining clinical cure.

A typical secondary case was as follows.

CASE 2.—A boy, aged 2½ years, had eight months' history of a primary lesion on the inner border of the right thigh and six months' history of multiple secondary lesions. The main sites were chin and neck, abdomen, pubis, perineum, and occiput. Nasal discharge and seborrhœa present. Ide test positive. Spirochætes demonstrated in the yaws in large numbers. Sodium penicillin 100,000 units was given over twelve hours intramuscularly.

Spirochætes disappeared from the yaws within nine hours. Within twenty-four hours the primary lesions had dried up and presented a pink glazed appearance; snuffles ceased. Within forty-eight hours all yaws showed thinning and shrinking of their crusts, and darkening and complete disappearance of the typical yellow colour, the whole giving an appearance of desiccation. Some lesions had already shown separation at the periphery. By six days all yaws had disappeared, leaving either a pale fairly sound skin at the site of the lesion or a grey-brown leathery surface. By ten days there was no evidence of active yaws, and the only stigmata left were the areas of scarring denoting the site of the original lesions. Ide test positive after twenty-one days. Eleven months after the start of treatment the cure had been sustained and there had been no relapse, the Ide test still being positive.

Tertiary Cases.—We treated 17 cases with bone lesions due to yaws: 11 gave immediate clinical remission of symptoms, and almost complete disappearance of osseous signs within sixteen and a half days; 4 showed improvement; and 2 did not respond to treatment at all.

We followed up 6 cases: 2 patients observed at four months, 1 at eight and a half months, and 2 at ten months were in good health. In 1 case there were clinical relapses at six weeks, and at four, seven, and eleven months, but nevertheless the Kahn reaction was negative at the last date.

There were also 2 cases of goundou, which is commonly regarded as a tertiary manifestation of yaws. Neither of them was cured, but 1 had relief from pain and considerable decrease of swelling.

TABLE IV—RESULTS OF TREATMENT WITH ARSENICALS ALONE OR PRECEDED BY ONE INJECTION OF PENICILLIN

Acetylarsol alone			Penicillin and acetylarsol			Neoarsphenamine alone			Penicillin and neoarsphenamine		
Cured	Improved	No change	Cured	Improved	No change	Cured	Improved	No change	Cured	Improved	No change
Secondary											
1	..	4	5	1	..	5	3	1	4	..	..
Tertiary											
3	4	8	9	3	2	11	3	3	12	..	4

Of 2 cases of foot yaws treated, 1 was clinically cured, and 1 showed considerable improvement immediately after treatment, and on examination seven months later was completely healed without any further treatment.

A typical tertiary case was as follows.

CASE 3.—A boy, aged 10 years, had had primary yaws two and a half years ago, and had a week's history of pain and swelling above the left wrist. Kahn and Ide tests positive. He had had tropical ulcers for many years.

April 14, 1945: radiography showed a yaws periostitis at lower end of right radius, with slight medullary rarefaction.

Sodium penicillin in beeswax and oil in daily dosage of 100,000 units was given intramuscularly for fifteen days. The arm was splinted. Within two days the pain subsided.

April 24: clinically much improved, with very little swelling; radiographic appearances showed no extension of lesion, and an area of increased translucency, with cortical erosion and periostitis, in the shaft of the radius 1 in. above the epiphyseal line.

May 5: pain and swelling had disappeared; clinical cure; radiography showed some regeneration of cancellous bone, and less translucency.

June 12: radiography showed a slightly decalcified oval area about 1 in. long in the lower radial shaft, with an associated thin layer of smoothly ossifying periostitis.

August 1: cure clinically sustained; Kahn and Ide tests both positive; radiography showed slight sclerosis and restoration of normal structure in the formerly translucent areas, and periosteum ossified and almost united to cortex.

Thus there was clinical cure after about a week, but radiologically the lesion progressed at one to two weeks, and then steadily retrogressed until, three and a half months afterwards, there was little evidence of former disease.

COMPARISON OF PENICILLIN AND ARSENICALS

To compare penicillin and arsenicals in the treatment of yaws, each of the following treatments was given in a few cases: (1) acetylarsol 1·25 g. daily for fourteen days; (2) one injection of penicillin 100,000 units in oil followed by acetylarsol 1·25 g. daily for fourteen days; (3) three weekly injections of neoarsphenamine 0·6 g.; (4) one injection of penicillin 100,000 units in oil followed by three weekly injections of neoarsphenamine 0·6 g. The results are given in table IV.

The period of observation has been a month; no reversal of Kahn has taken place. Though the series is obviously too small to allow any definite conclusion, a single injection of penicillin followed by acetylarsol seems to be preferable to acetylarsol alone, but with neoarsphenamine the synergic action of penicillin is not in evidence. Of the 62 tertiary cases treated, 11 had yaws ulcers. The result of treatment of the cases with ulcers was as follows:

Treatment	*Cured*	*Improved*	*No change*
Acetylarsol	1	2	1
Penicillin and acetylarsol	2	1	..
Neoarsphenamine	3	..	..
Penicillin and neoarsphenamine	1	..	..

DISCUSSION

In most cases the penicillin dosage consisted of 100,000 units in oil injected intramuscularly once or twice daily, the object being to obtain a continued low concentration of penicillin in the blood, as distinct from the initial peak followed by rapid elimination of penicillin, which is produced by an intramuscular injection of the drug dissolved in saline (Fleming et al. 1944).

McDermott et al. (1945) suggest that, in the treatment of syphilis by repeated doses of penicillin, a minimal effective level need not be maintained absolutely continuously. Intermittent treatment, aimed at obtaining a minimal effective concentration in the blood at intervals corresponding to the growth phases of the spirochæte, would be as efficient. This may well apply to yaws.

Disappearance of the organisms from the yaws lesion does not appear to be influenced by the amount, above a minimal concentration, of the single or the total dosage of penicillin, a fact also noted in syphilis by Moore et al. (1944).

Our results showed that in 12 of 14 cases with primary lesions, and in 78 of 81 cases with secondary lesions, healing took place in an average period of nine and eight and a half days respectively. Out of 17 cases with bony lesions (tertiary), 11 showed complete disappearance of signs and symptoms, and 4 were improved at an early date. Of 2 cases of goundou, 1 showed a slight response and 1 no response at all. The results with penicillin compare favourably with those of other forms of treatment, an important feature being the absence of toxic reactions.

In both syphilis and yaws it is well recognised that, though it is possible to clear up the lesions of the primary and secondary stages with comparative ease, protracted observation is essential if the final results of treatment are to be evaluated. This applies as much, if not more, to yaws. Many African soldiers, for instance, are seen with active tertiary yaws of recent onset who say that years ago they had a series of injections of a yellow fluid into the vein of the arm. It is therefore fully realised that the period of observation of our own cases—and this applies also to all other investigations so far reported on penicillin in yaws—is far too short to allow of final judgment being passed.

In the present series, out of 5 primary cases originally cured and observed during a period of four to seven months, 1 relapsed; out of 45 secondary cases originally cured 3 relapsed during a period of one to twelve months; and during a similar period 1 tertiary case relapsed out of 6.

In yaws there appears to be considerable uncertainty as to how far serological reactions are a significant guide to ultimate cure. In the present series treated with penicillin, the following results were obtained in sustained cures of primary, secondary, and tertiary yaws:

Period of observation (months)	*No. of cases*	*Kahn positive*	*Kahn negative*
1½–3	43	42	1
4 – 6	38	33	5
7 – 9	38	25	13
10 –12	12	11	1

The number of serological reversals was thus small, and it seems that a serologically positive reaction does not necessarily mean lack of therapeutic response. If this is so, serological controls should at the most act as a guide to treatment rather than as a test of permanent cure.

During a short period of observation Whitehill and Austrian (1944) were unable to determine any effect of penicillin treatment on the serum Kahn reaction in yaws, even though the dosage they used was about 1,000,000 units. On the other hand, da Cunha et al (1944a and b), though they used only 9600–54,000 units, claim to have obtained complete reversal of the Wassermann reaction in 8 out of 11 cases, and in a further case the Wassermann reaction was negative at the beginning of treatment and remained negative. No explanation is forthcoming for the different results in the serological reactions obtained in West Africa and Fiji on the one hand, and in Brazil on the other.

A striking result of penicillin treatment has been the change in the granulomatous bone lesions of tertiary yaws. According to Goldmann and Smith (1943), without treatment the osseous lesions of yaws invariably become worse, either with thinning of the cortex and subsequent deformity, or with bone thickening, so that the medulla is encroached on and the line of demarcation between medulla and cortex is lost. This picture may remain unchanged for years or may slowly progress to give the appearance of "marble bone."

As shown radiologically, there is after treatment a very rapid rarefaction of bone, a process which suggests a deterioration, were it not that the clinical signs indicate improvement. This initial rarefaction, which is similar to that observed in penicillin-treated cases of coccal infection of bone, is followed by a rapid formation of normal new bone. Stokes et al. (1944) found that bony lesions in syphilis treated with penicillin healed in from one to six and a half weeks, but they make no mention of radiological control of the healing process. Helfet (1944), in yaws treated with either neoarsphenanine or bismuth and 'Sulphostab,' found relief from pain in the bones in one or two weeks, with some early healing of the osseous lesions in six weeks. Our experience of the osseous lesions of tertiary yaws treated with 'Sobita' or with neoarsphenamine indicates a much slower period of healing than with penicillin.

At this stage it would be foolish to compare the permanent results of penicillin treatment of yaws with those obtained with such drugs as neoarsphenamine, acetylarsol, and sobita, but penicillin clearly has some advantages over bismuth and the arsenicals. The rapidity with which the lesions begin to heal is remarkable and has an excellent psychological effect on African patients. The single daily intramuscular injection allows the therapeutic course to be completed in a much shorter time than with either sobita or the arsenicals, an advantage both to those who are giving numerous injections and to the patients, whose attendance is more likely to be regular. Penicillin is far less liable to cause toxic reactions than either arsenical or bismuth preparations. As mentioned previously, Findlay et al. (1944) in one instance found that the lesions of both yaws and of bismuth stomatitis, associated with spirochætes and fusiform bacilli, were rapidly removed by penicillin.

Preliminary observations suggest that acetylarsol and penicillin in combination may act synergically on the spirochætes of yaws, and that penicillin for the acute stage, followed by protracted arsenical therapy, is possibly the ideal treatment if complete and lasting cure is to be attained. Whether, in an area where the possibility of reinfection is by no means remote, it is desirable to effect a radical cure is a problem which requires much fuller investigation.

In the two small villages from which the bulk of our patients were derived there has not appeared any case of primary or secondary yaws in the last five months, suggesting that, if all early cases could be promptly treated and rendered non-infectious, the incidence of yaws in particular areas might be greatly reduced.

SUMMARY

In 128 cases of yaws (15 primary, 96 secondary, and 17 tertiary) treated with penicillin the method of choice was a daily injection of 100,000 Oxford units in groundnut oil and beeswax, up to a total dosage of at least 1,000,000 units.

Spirochætes disappeared from the lesions in 9–24 hours after doses of 50,000–200,000 units.

There was remarkably rapid healing of the acute lesion in primary and secondary yaws, the average times being 9 and $8^{1}/_{2}$ days respectively.

With bony lesions of tertiary yaws considerable success was achieved both clinically and radiologically in a few weeks.

No correspondence could be found in the follow-up investigations between sustained clinical cure and reversal of Kahn reaction.

In 20 cases penicillin was given with either acetylarsol or neoarsphenamine. The results suggest that penicillin in the acute stage, followed by a more prolonged arsenical treatment, is the ideal therapy for ultimate and permanent cure, but further controlled observations are required.

Our thanks are due to Brigadier H. B. F. Dixon, D.D.M.S., West Africa Command, and the Director of Medical Services (Colonial Medical Service), Gold Coast, for permission to publish these observations; and to Dr. O. Ampofo and Mr. A. Kpeglo. Private Amoah, W.A.A.M.C., gave us much assistance.

THE USES OF PLASTICS IN SURGERY

GEORGE BLAINE
M.D. Berlin, L.R.C.P.E.
MAJOR R.A.M.C.; LATE OF THE DIRECTORATE OF BIOLOGICAL RESEARCH, WAR OFFICE

IN the last few years plastic chemistry has developed a number of new materials and has shown that many biochemical substances possess plastic properties which can usefully be applied in surgery. Most of the fundamental and pioneering applied work has been done in Great Britain and in North America.

Since instruction in plastics is not included in the medical curriculum, a summary of their salient characteristics is a necessary preliminary to a survey of their place in surgical practice.

Plastics are chemical substances of high molecular weight. They are deformable (mouldable) under suitable conditions and retain their acquired shape thereafter in a normal environment. They are versatile in that the end-product of the plastic process can be given different physical properties. For instance, some plastic might be made into a moulded ivory-hard object, a flexible rubbery mass, a thin adhesive film, a yarn that might be woven into fabric, or a highly porous spongy or foam-like structure. Provided they fulfil the requisite criteria of surgery they can be used in place of existing materials, and in some cases they make new surgical procedures possible.

Plastics can be grouped according to their physical and chemical behaviour and divided into absorbable and non-absorbable materials according to their interaction with living tissue (Blaine 1945a). The accompanying table gives the facts of interest to the surgeon.

SPECIAL APPLICATIONS

In *bone surgery* plastic materials have been used for filling gaps in the cranial vault and facial bones. Acrylics have been found most useful for this. After animal experiments had proved the harmlessness of polymethyl methacrylate in trephine holes of the cranium of the cat (Blaine 1946a) and rabbit (Beck et al. 1945), Small and Graham (1945) reported 30 cases in which acrylic obturators had been used in filling cranial defects. Shelden et al. (1944) used entire acrylic "cranial vaults" in investigations on shock in monkeys. A good description of the current "dental" technique of use of acrylics is found in both these papers.

Attention has to be drawn to the late behaviour of acrylic plates in bone gaps. Sometimes the plate, quiescent for six months or more, has become loose and worked its way to the surface (Blaine 1945b). This was more likely to happen where transplanted skin was used to provide skin cover; experimentally it happened regularly where the bulk of the implant caused tension in surrounding tissue and possibly interfered with vascularisation. I have seen two cases where acrylic plates were used in covering defects after operations on the frontal sinus; in one case the plate was firm for three years before it became loose; it could be moved about under the skin but it caused otherwise no discomfort. There was no tendency in this case for the plate to "work itself out."

Acrylics are currently used with the "dental impression" technique. Many excellent descriptions, with as many individual modifications, are available, and two have been referred to above. The use of this method demands the assistance of trained dental mechanics and necessitates a two-stage operation: in the first stage the impression of the gap contour is taken; in the second the finished prosthesis is fitted. The use of this technique is an obvious drawback and provides, in comparison with tantalum, the advantages of radiolucency and cheapness only; many brain surgeons consider it more complicated than the fashioning of a bone graft to the gap.

Two methods have been described and demonstrated (Blaine 1945a) which permit the use of acrylics in one stage. The one makes use of ultraviolet-ray acceleration of polymerisation (setting) of "activated" acrylic dough, formed in situ; the other method makes use of the "thermoplastic" properties of preformed unplasticised methyl methacrylate sheet. This sheet when heated to 130° C becomes readily mouldable and soft to handle. Pressed to a model it takes the exact shape of the "master" and retains this acquired shape on rapid cooling. Either of these methods enables methyl methacrylate to be used in a short time, say 15–20 min. A detailed description of the methods is given elsewhere (Blaine 1946a). Another simplified in-situ process has since been developed and will be described shortly.

Harmon (1943) described the use of acrylic "joint-caps" in the operative treatment of arthritis of the hip and in the reconstruction of the small joints of the hand and foot. Very little has been heard of this application since the first paper on the subject, and it is therefore difficult to evaluate its usefulness in comparison with the metals.

It may be remarked that indifferent and frankly bad results following the use of acrylics in these and other fields might well be due to the purely practical exploitation of acrylics, inevitable in war-time, without due attention to fundamental physiological research; it must be realised that reaction to acrylics varies with the amounts and nature of plasticisers and other added substances which are found in most commercial preparations. Cutler (1946) expressed himself particularly forcibly on this subject, drawing attention to the "mere trickle" of really scientific dental contributions in this specialised subject, as against the spate of technical articles and notes.

In *dental and faciomaxillary work* acrylics are now well established. Many appliances formerly made of precious metal are now made of these plastics, as a routine. Clarkson et al. (1946) summarise the work of the faciomaxillary units in the Central Mediterranean Force; about 90 acrylic Gunning splints were fixed in 45 cases of fracture of the edentulous jaw.

Acrylic splints are enthusiastically recommended (McGowan 1945, Scales and Herschell 1945, Cholmeley 1945) for splinting forearms and wrists, and at the National Orthopædic Hospital at Stanmore a method has been devised for adapting acrylic sheet for use as a spinal jacket.

At present acrylic splints hardly fulfil all the criteria one ought to apply to new materials replacing old and trusted ones (see Blaine 1945b). However attractive and elegant a plastic splint or appliance looks, its direct moulding to the human frame requires greater heat than the operator's hands and the patient's skin will tolerate; its "indirect" application by the dental method is too complicated; the fact that it does not absorb moisture is hardly as advantageous as has been claimed (McGowan 1945). The plastic splint allows sweat to accumulate; pruritus develops, and the odour of the skin fully counteracts the elegant appearance, lightness, radiolucency, and "washable" nature of the splint. However, in cases where the splint can be removed daily—e.g., in radial nerve palsy—acrylic splints are useful.

I have used acrylic dough (of the commercial type) for splinting a forearm in a patient who volunteered for this treatment. The method consisted of the application of the "kneaded" and "flat-rolled" dough to the limb; the dough could be cut with a pair of scissors. The splinted limb was exposed to the rays of the tropical sun to accelerate the setting of the plastic. Though the result was mechanically excellent, the dough caused acute dermatitis and had to be removed on the second day. Whether specially treated dough would be more satisfactory remains to be seen. Excess monomer was probably responsible for the dermatitis.

Before any plastic is recommended to replace plaster-of-paris in orthopædic splinting, it is well to bear in mind that it would have to possess the following properties: cheapness; foolproof handling: quick setting without complicated machinery; and porosity. Were these added to the existing properties of plastics—radiolucency, lightness, elegance, and the fact that they allow the patient to wash and bathe—the plastic splint or spinal appliance would come to stay.

OPHTHALMOLOGICAL USES

Contact lenses and artificial eyes made from acrylic plastics do not break easily, but they are easily scratched, and their cost is relatively high (Stewart 1946).

Flexible rubber-like plastics of the polyvinyl group are increasingly used as drainage-tubes (Mann 1945) and take the place of rubber on many an anæsthetic airway (Thornton 1944). The tolerance of tissues to polyvinyls varies, however, and it must be remembered that this material is always plasticised and that countless varieties exist. Before these materials are recommended for use, the tolerance of tissues to the different makes will have to be established.

Polyvinyls are also used as soft-tissue prostheses (masks) in plastic surgery. Reports from the U.S.A. (Lougee 1943) and from Australia (Woerner et al. 1945) are encouraging. The polyvinyls are, however, photosensitive and cannot therefore be worn indefinitely (Office of Scientific Research and Development 1943).

In *suture materials* plastic chemistry produced 'Nylon,' the popularity of which makes further comment unnecessary. The reaction of the tissues to it is excellent (Aries 1941); its only drawback is that the material slips, and knots have to be double and tied with great care.

ABSORPTION

The finding that certain plastics were absorbable was perhaps the most important step in the development of plastics for surgical uses. Research was long directed towards the development of absorbable materials for surgery. Used as thin homogeneous films such materials are required to "isolate" healing tissues, thus preventing the formation of adhesions. Amnioplastin, used for some time, was found unsatisfactory by Rogers (1943). Used as carriers of biochemical hæmostatics, such as thrombin, they must facilitate control of capillary oozing. Woven into gauze-like fabric they can control hæmorrhages otherwise difficult to deal with. They can possibly also be used as vehicles for penicillin and thus ensure a more prolonged action. Painted or sprayed over surface wounds and burns they can combine the advantages of the open and closed methods of treatment. *The ideal absorbable material must naturally be sterilisable by heat* and compatible with added substances, and its handling must be simple.

The first practical development was made with oxidised cellulose (Frantz 1943, Frantz and Lattes 1945, Frantz et al. 1946). Suitably treated cellulose (oxycellulose) was woven into gauze and made into film and foam; it was found that it could carry thrombin. Experiments have shown that it was readily absorbable with a

CHARACTERISTICS AND SURGICAL USES OF PLASTICS

Material	Physical form in which used	Tissue reaction	Sterilisability	Uses
ylic (polyethyl meth-rylate)	Processed and moulded plates, dough, and ultra-violet-sensitised dough	Mild fibrous reaction to all physical forms; no giant cells; some solvents—e.g., acetone—irritant	By heat and pressure; plasticised material undergoes some deformation	Cranial and faciomaxillary obturators, plates; external prostheses
ulose acetate	Flexible films	Massive fibrous tissue formed around implant (Graef and Page 1940)	By heat and pressure	Experimentally for producing "armour plating" round kidney and blood-vessels
thyl cellulose	Solution	Not tested	By heat and pressure	Experimentally as plasma substitute
olyamide ('Nylon')	Filament yarns, solid plates	Mild fibrous reaction; no giant cells	By heat and pressure	Suture materials; experimental bone plates and screws
ea and phenolic resins	Resin, for coating and moulding cloth	The resins are highly irritant	Sterile	Experimentally as splints
olyvinyl chloride	Flexible sheets, tubes, blocks	Variable reaction depending on added materials	By heat and pressure	Drainage-tubes, airways, facial prostheses
olyvinyl alcohol	Solution	Not tested	By heat and pressure	Experimentally as plasma substitute
asein	Solid rods, blocks, film-forming emulsions	Transient aseptic inflammation during absorption	Deforms on heat-treatment unless specially packed	Experimental bone plates and screws; films in treatment of burns
ibrin and fibrinogen	Solid blocks, foam, film; with thrombin "in situ" formed clots	ditto	By formalin treatment only; not sterilisable by heat	Tissue-isolating films, cover of dural defects, hæmostasis
elatin	Porous elastic "sponge"	ditto	By heat and pressure	ditto
xycellulose ..	Woven fabric as gauze, cotton-wool; solution	ditto (less highly oxidised material creates fibrous reaction)	By formalin treatment only	ditto (also experimental plasma substitute)
Alginates ..	Woven fabric as gauze, cotton-wool, film, foam sponge; solution of sodium salt with $CaCl_2$ for "in situ" clotting and plasma clotting	Mild aseptic inflammation in course of absorption	By heat and pressure	ditto

comparatively minimal tissue-reaction. Clinical use was made of it in neurosurgery; it was satisfactory as a thrombin carrier and controlled capillary hæmorrhage in brain surgery. In general surgery it was used to control hæmorrhage from highly vascular organs. Drawbacks of this material are that it cannot be sterilised by heat and is incompatible with penicillin, reducing the potency of the drug. It destroys penicillin preparations.

PROTEIN PLASTICS

About the same time when the uses of oxycellulose were published it was found, almost simultaneously in the U.S.A. (Ingraham and Bailey 1944, Bailey and Ingraham 1944) and in Britain (Blaine 1945a), that proteins possessed suitable plastic properties.

Fibrin.—In course of plasma-protein fractionation experiments at Harvard Medical School and elsewhere fibrin was particularly experimented with in this connexion. Fibrin was made into film and foam and into a sprayable solution. Used in covering dural defects the film was found highly satisfactory (Ingraham and Bailey 1944, Bailey and Ingraham 1944). As a foam in combination with thrombin it proved of great help in arresting capillary hæmorrhage. Sprayed on burns and clotted with thrombin it was also useful.

Drawbacks to the ubiquitous use of fibrin (or fibrinogen) plastics are their non-sterilisability by heat and the relatively complicated and expensive method of their production. Used experimentally in the treatment of scleral wounds (Blaine et al. 1944) it was found too quickly absorbable, though it fulfilled the other criteria admirably. Workers in the U.S.A. reported persistence of fibrin film for about 80 days over the dura (Ingraham and Bailey 1944).

Casein.—In Britain the protein-plastic experiments were mainly directed towards the development of solid plastic appliances as plates and screws for the internal fixation of fractures (Blaine 1945a, 1946a). Though the initial physical properties of *casein* plastic—the protein predominantly used—were promising, such plastic softened in tissue too early to be of use.

Casein plastic films formed in situ were used by Curtis and Brewer (1944) for burns. Their results speak well of this method.

Gelatin.—Light and Prentice (1945) described the use of gelatin plastic sponge, 'Gelfoam,' as a thrombin carrier. The easy handling and availability of the material makes it a very promising foam in hæmostasis.

Alginates.—The latest development in absorbable plastics to be used as a tissue isolator, absorbable gauze, cotton-wool, and a "carrier" of added substances in the form of a foam, film, or gel is the adaptation of alginate products to surgery (Blaine 1946b). These are a derivative of seaweed; though not generally known and developed as a plastic, certain of its salts possess plastic properties.

Evidence has been presented that certain alginate products are absorbable in tissue, sterilisable by heat, and compatible with penicillin (Blaine et al. 1944, Blaine 1946b). Used (also in combination with plasma as an alginate-plasma film) as "puncture patches" over scleral defects, alginate film was found satisfactory both experimentally and clinically (Blaine 1946b). There is, however, no further report of its use in this connexion in this country. Alginate films clotted in situ with calcium chloride (the quick clotting of the sodium alginate solution under the action of calcium chloride is particularly noteworthy) were used by me in the treatment of wounds and burns in troopship hospitals in the Far East. Results were very encouraging, but lack of facilities and "exigencies of the Service" made it unpractical to follow up the cases methodically. The same holds good for penicillin "carriage" experiments.

Gough (1945), in the National School of Medicine in Wales, reported the usefulness of alginate gels in the sealing of bronchi in the surgical treatment of pulmonary tuberculosis.

PLASTIC SOLUTIONS

Experimental use of plastic solutions was made in the search for plasma substitutes in blood-transfusion. Sodium alginate (Solandt 1941), methyl cellulose, and polyvinyl alcohol (Roome et al. 1944) were reported on in this field of research. Polyvinyl alcohol alone showed sufficient promise. Roome et al. (1944) in Canada found that it was well tolerated by patients.

CONCLUSION

It will be seen that a considerable amount of work was carried out, mostly under the stimulus of war-time needs of surgery, in this newest field of experimental surgery. Further research might produce many a useful innovation. One factor must be borne in mind. The plastic industry is not ancillary (like the pharmaceutical industry) to the medical profession. Stimulus for further work in these fields must therefore come from the surgeon.

Medical Societies

TUBERCULOSIS ASSOCIATION

AT a meeting in London on Sept. 20, with Dr. NORMAN TATTERSALL, the president, in the chair, a paper on

Tuberculosis of the Nervous System

was read by Dr. HONOR SMITH. She said that while there are powerful new weapons against purulent meningitis, the tuberculous form is still as great a therapeutic problem as when Whytt first described it in 1768, though hopes are now raised by streptomycin.

Apart from Pott's disease, there were two types of infection—meningitis and the much rarer large tuberculoma. The latter presented as an expanding lesion, with raised intracranial pressure and localising signs; the diagnosis was from tumour or abscess, and though tuberculosis elsewhere was a pointer, biopsy was sometimes necessary for diagnosis. Radiological evidence of calcification was not pathognomonic; it was, for example, seen with gliomata. Removal of a tuberculoma did not necessarily result in tuberculous meningitis; of 6 cases operated on at the Nuffield Department of Surgery, Oxford, 4 had recovered completely. A simple decompression might suffice, especially with cerebellar tuberculomata.

Tuberculous meningitis was said by Rich and McCordock to result from rupture of a tuberculous focus into the ventricles or subarachnoid space. Dr. Smith said she had found small tuberculomata with meningitis, but their piecemeal removal did not inevitably result in meningitis. Of 25 cases of tuberculous meningitis, rather more than half were over ten years of age. The insidious prodromal phase might be due to concomitant miliary tuberculosis rather than to meningeal involvement. The stages of nervous involvement were as follows:

1. *Meningeal Irritation.*—This might be absent or hard to detect in infants. There was evidence (O'Connell) that it was due to irritation of the posterior nerve-roots. The site of the exudate might substantially influence the effect of chemotherapeusis.

2. *Signs of Raised Intracranial Pressure.*—Headache was closely paralleled by vomiting. The further increase in pressure at a later stage was usually due to obstructive hydrocephalus.

3. *Mental Changes.*—There might be a change of temperament, succeeded later by delirium, and finally stupor or coma.

4. *Epilepsy.*—When this occurred it was usually at the end of the prodromal phase and was focal or jacksonian.

5. *Focal Signs.*—These might include ophthalmoplegia, extensor plantar responses (often unilateral), and hemiplegia or paraplegia. They might be caused by tuberculomata, or by vascular occlusion and infarcts. Chemotherapeusis, to be effective, must act before these vascular changes developed.

The average chloride content of the cerebrospinal fluid (C.S.F.) was 650 mg. per 100 c.cm., as compared with 663 mg. in a series of pneumococcal meningitis; but in half the tuberculous patients the content was less than 600 mg. The chloride level might be depleted by persistent vomiting (as also in pyogenic meningitis) or it might be raised owing to uræmia. The content was usually less than normal, but there was no diagnostic level. Differentiation from pyogenic meningitis might be aided by the discovery of tuberculosis elsewhere in the body and by a positive family history; and a history of a pyogenic focus might cause confusion. Unfortunately, tubercle bacilli could seldom be found in the C.S.F. Ventriculography might show a moderate symmetrical hydrocephalus, which was diagnostic. When the diagnosis was in doubt the condition might justifiably be treated as a pyogenic infection.

Dr. P. DANIELS remarked that the capacity of patients with severe pyogenic meningitis for almost complete recovery after suitable treatment encouraged hope for the successful treatment of tuberculosis of the central nervous system. If an effective drug were found it must be applied early; with complete blockage of C.S.F. circulation the condition became almost hopeless, and the changes with infarction were irreversible, though there might be some improvement with resolution of surrounding œdema.

Treatment of Lupus Vulgaris

Dr. G. B. DOWLING said that lupus, though uncommon, was extremely chronic; there was thus always a pool of affected patients, who constituted a serious social problem. In this country the larger general hospitals bore the brunt of treatment. In Denmark the Finsen Institute treated all cases, numbering, in the ten year between 1914 and 1923, 975, of which 735 were cured, chiefly by local Finsen therapy, carbon-arc baths, heliotherapy, and nutritional remedies; other methods, such as diathermy and cautery, pyrogallol and other caustics, and surgical excision, had also been used. He thought that treatment would be materially helped by intensive vitamin-D therapy, but that there was still need for skilful local treatment.

The first patient treated intensively with vitamin D had had local treatment for five years; he was ordered 150,000 I.U. daily without much confidence in success. The condition was almost cured after $2^{1}/_{2}$ months. There were, however, two relapses, the first within a few weeks with congestion and swelling of the area; moreover, two small lupus nodules embedded in scar tissue were untouched. Between 1943 and 1945 Dr. Dowling d Dr. Prosser Thomas had treated 32 cases: 18 had en cured and 9 much improved. These patients had ceived very little local therapy, in contrast to similar roups treated by Charpy from 1941 onwards. With xic symptoms—nausea, malaise, and sometimes vomit- g—the usual dose of 3 high-potency 'Ostelin' tablets aily might have to be reduced. Hypercalcæmia occurred rratically and was not necessarily associated with toxic ymptoms or improvement of the condition.

Calciferol in Tuberculous Conditions

Dr. D. E. MACRAE described a trial of calciferol in 20 ong-standing cases of lupus vulgaris, in which the verage duration of the disease exceeded nineteen years. f these, 14 had so far been discharged as clear of disease. esults could be summarised as follows: (1) profuse oft granulations, easily removed by scraping, required dditional local treatment; (2) raised firm plaques esponded well; (3) more deep-seated lesions, level with he skin, responded well; (4) isolated nodules responded n the whole badly; (5) with lesions inside the mouth, ose, and larynx the results were mixed; and (6) with multiple areas of affection, the larger the areas the slower the response. During the first 2–3 weeks there was a reaction; patches became angrier and isolated nodules more scarlet, and spontaneous ulcers might develop. Calciferol, he suggested, acted by promoting reaction in the lupus tissue; this resulted in some general toxæmia, as shown by a stronger tuberculin reaction and increased blood-sedimentation rate; and it was succeeded by fibrosis which "literally squeezes the lupus to death." The effect did not seem to be influenced by either the method of administration or by altered calcium metabolism. The addition of local therapy hastened improvement.

He had also observed improvement with calciferol in 2 cases of adenitis, though in these again there was an initial reaction, with softening and pus-formation; and in 1 case of advanced wrist tuberculosis, 1 case of multiple dactylitis, and 1 case of tuberculous cystitis; though these had shown unexpectedly rapid improvement, no precise claims could yet be advanced for calciferol in these conditions.

He had twice seen calciferol treatment complicated by abdominal discomfort and constipation proceeding eventually to coma, peripheral neuritis, and optic atrophy; both patients had ultimately recovered. There had been no evidence of treatment causing renal damage; but calciferol should probably not be given to completely recumbent patients; and the possibility of the initial reaction causing a flare-up necessitated caution where there was active lung disease.

Dr. EMRYS JONES, of Cardiff, said that lupus, usually of long standing, had cleared with calciferol in 16 out of 18 patients. Adenitis also had been cured with this treatment; the periadenitis seemed to clear up first, so that the glands became more discrete.

Dr. M. C. WILKINSON referred to the effect on resistance of increase in the body sterols, and quoted a case of lupus which had cleared up when the patient became pregnant. So far he had not been impressed with the effect of calciferol on tuberculosis of bones and joints.

PRODUCTION OF STREPTOMYCIN.—At a recent press conference held at the London headquarters of Messrs. Boots, Sir Jack Drummond, F.R.S., described the process employed in the manufacture of streptomycin. In the surface-culture method spores of the *Actinomyces griseus* are sprayed on the surface of a medium containing sugar and meat extract or corn steep liquor filled into milk bottles from a conveyor belt (some 250,000 milk bottles are in use). Streptomycin is excreted in measurable quantities after the 7th day, and after 14 days the mould is discarded and the liquor made acid and pumped through charcoal filters which absorb the impurities. After further purification and freeze-drying a white powder emerges which is packed into sterile ampoules. The cost of producing sufficient streptomycin for the three-months course of treatment at present considered necessary for a case of tuberculosis works out, on the basis of American costs, at about £3000, employing the surface-culture process. Messrs. Boots are planning to replace surface culture in bottles by deep culture in huge tanks, and by this process the cost may be reduced to a quarter of the present figure.

Reviews of Books

Abnormal Behaviour

R. G. GORDON, M.D., D.SC., F.R.C.P., late medical director, Child Guidance Council. London Medical Publications. Pp. 75. 5s.

Dr. Gordon writes with the freshness and charm of an acknowledged master, but he spends too many of his 75 pages on going over old ground; consequently, when he comes to the problems of capital and corporal punishment he disposes of them with "it is impossible to go into all the arguments which might be advanced in this complicated problem." This is just the sort of topic, however, about which readers would be glad to see the arguments set out with Dr. Gordon's objectivity. Dealing with the question of punishment, Dr. Gordon sticks to the familiar three purposes—retribution, deterrence, reform—and does not attempt to break new ground. When he comes to the practical issues he writes with good sense and wisdom and makes a convincing case for the psychological attitude. His tolerance, his kindliness, and his obvious soundness must help to win understanding and sympathy for the mentally abnormal.

The Ship Captain's Medical Guide

(18th ed.) Ministry of War Transport, London. H.M. Stationery Office. Pp. 225. 3s. 6d.

NEARLY twenty years have elapsed since the last edition of this venerable publication, and pending a complete revision the compilers have made a determined effort to bring it up to date by rewriting 11 of the 24 chapters and introducing material from *First Aid in the Royal Navy 1943*. The ingenious Neil Robertson stretcher is described in detail, with a series of good photographs to demonstrate its use. The diagrams throughout the book are useful.

Much of the elegant 18th-century English of the original composition, and some of the remedies current at the time, have been retained. The burning of feathers under the nose of the fainting patient is highly commended, and the amount of castor oil and Epsom salts consumed by the patients should keep the ship's lavatory accommodation fully occupied. Any suggestion of heart weakness may be countered by the exhibition of brandy, whisky, or gin at two-hourly intervals, and in the case of the apparently drowned 4 tablespoonfuls are advised as an enema, a pleasure which we must regretfully deny our patients ashore. The style throughout is dogmatic and obviously intended to inspire confidence in the master and his patient. In the background one can almost hear the clanking of irons for any who raise their voices in dissent. We quote one paragraph without comment:

> "PLEURISY. . . . If the patient is robust a tablespoonful of Epsom Salts in just sufficient water to dissolve it should be given every morning. This produces copious liquid discharges and helps to get rid of the accumulation of fluid in the chest by draining it through the bowel."

There is a fine nautical description of appendicitis, commencing with a sudden pain in the south-west corner of the abdomen; but as suspected appendicitis is the biggest bogy facing the unqualified ship's doctor it would be better to rewrite this chapter and say that most cases start with central pain, backing later to south-west, localising, and with the onset of peritonitis veering south and east. McBurney's point is incorrectly described; few surgeons would agree with 4 oz. of milk or liquid nourishment being given every two hours; and the instruction to give a dose of castor oil as soon as the pain and tenderness disappear (when the appendix bursts, for instance) is dangerous.

Since much of the book is concerned with good hygiene, it is odd to find modern fungicides and D.D.T. completely omitted. Penicillin is not even mentioned, though most American ships carry a supply with a purser instructed in its use. All senior officers in our Merchant Navy are required to pass a course in first aid, and it would require little more instruction to enable them to clear up their cases of gonorrhœa with 200,000 units of penicillin or to use the same technique as a life-saver for cases of pneumonia or appendicitis in mid-Atlantic. Where common sense obtains the text is magnificent.

Among the usual anti-shock treatment we find the following splendid advice:

> "CHEER HIM UP. . . . Remember that a casualty is wondering what has happened, whether he is going to live or die and whether, if he lives, he is going to be scarred or mutilated for life. His thoughts are turning in a lonely little personal world of fear, no matter how brave a man he may be. All this mental worry serves to increase his shock and it can be lessened very much by a sympathetic shipmate. Talk to him, be natural . . . and while talking near injured men, never whisper."

We wish all the book was as good as this.

Forensic Medicine

(4th ed.) DOUGLAS KERR, M.D., F.R.C.P.E., D.P.H., lecturer in forensic medicine, School of Medicine, Royal Colleges of Edinburgh. London: A. & C. Black. Pp. 359. 18s.

Douglas Kerr's well-known textbook continues to enjoy the affection and regard of both the student and his teacher. It is so readable, so reasonable, so reliable, and so free from the recondite that ruins many standard textbooks as they achieve success. This fourth edition in some ten years has been augmented with benefit, and new illustrations have been added. References might be better chosen: in toxicology, especially, there is much useful new reading on industrial aspects. The new material—on blood and head injuries in particular—is as clear as the rest. How eminently reasonable it all is, and what sound witnesses we should all be if we digested its principles. The time has come, however, to reduce the references to the pharmacy laws to essentials, and to cut down the sections on artificial respiration and Binet-Simon tests, and the verbatim judgments such as that on Rex v. Savage. And the examiner would have an easier time if the "Schedule to an Order in Council dated April 13th 1937 (S.R. & O. 1937. No. 327)" (sic) were stated, and if no doubts were roused on the gestation at which the law recognises viability. But how little there is in this good book with which to differ. Kerr remains a shining example of clear teaching for the student, readable to a degree.

Food and Nutrition

The Physiological Bases of Human Nutrition. E. W. H. CRUICKSHANK, M.D. Aberd., D.SC. Lond., PH.D. Camb., M.R.C.P., regius professor of physiology in the University of Aberdeen. Edinburgh: E. & S. Livingstone. Pp. 326. 16s.

THE author of this addition to the numerous textbooks on nutrition has in mind medical practitioners, medical students, candidates for the diploma in public health, and sociologically minded laymen. But it is a book with a difference: though the basic science is all there—and well set out—there is much emphasis upon the sociological implications and applications of the science of nutrition. In fact the author introduces the subject with no less than four interesting and valuable chapters on the evolution of human dietaries, the problem of world malnutrition, and the problem of nutrition in Great Britain in 1939–45 and in the coming years. And then, having polished off the science of the subject in six chapters, with three more on foods, he reverts to dietary planning, the appraisal of the nutritional state of individuals and communities, and the Food and Agriculture Organisation. There are numerous digressions into the histories of foods and the science of nutrition for which the author will be both thanked and criticised.

Sciatiques et lombalgies

par hernie postérieure des disques intervertébraux. D. PETIT-DUTAILLIS, professeur de pathologie chirurgicale, Paris; S. DE SÈZE. Paris: Masson. Pp. 178. Fr. 235.

THIS book is a full and straightforward account of the anatomy, pathology, clinical features, and treatment of prolapse of the intervertebral disk, and most of what the authors have to say will meet with general agreement in this country. They emphasise the frequency with which sciatica may be complicated by paralysis below the knee; and they use intrathecal iodised oil as a routine in diagnosis, where we have learnt to do without it. Their operative approach is a full laminectomy done under local anæsthesia, and the extradural removal of the prolapse is supplemented by division of the sensory root on both sides at the level of the lesion.

Pathology of the Central Nervous System

(2nd ed.) CYRIL B. COURVILLE, M.D., professor of nervous diseases, College of Medical Evangelist, Los Angeles. London: H. K. Lewis. Pp. 450. 36s.

THE second edition of this book has been somewhat expanded to include recent work on problems of the circulation, infection, and some neoplastic and degenerative diseases. Special attention is paid to the effects of trauma and bony diseases of the cranium and spine. Rather more space might have been given to the important subject of the virus infections, and more might with advantage have been said about the postexanthematous demyelinating diseases and their relationship to disseminated sclerosis. The presentation is clear and the micro- and macro-photographs and diagrams are well chosen and reproduced. The book is comprehensive and well written, and lays a sound foundation in neuropathology for the student of neurology or general medicine.

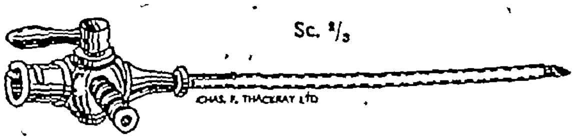
New Inventions

NEEDLE AND CANNULA FOR CHEST EXPLORATION

ONE of the dangers associated with the aspiration of the pleural space is spontaneous pneumothorax. It is not perhaps a very common one, but experience on a thoracic surgical unit, where aspiration is an everyday occurrence and forms a major part of treatment, shows that it is sufficiently common, in spite of the most careful technique, to justify efforts to reduce its incidence to a minimum.

The danger lies in the penetration of the lung with the large aspirating needle used, but this alone need not necessarily give rise to spontaneous pneumothorax. The latter is far more likely to develop as the result of unnecessary manipulations of the needle when the pleural space has been entered, and it should be the main rule in chest exploration to avoid these manipulations.

The special needle (incorporating a two-way attachment) described below and in the accompanying diagram was devised with a view to minimising this danger, and has been used extensively in the thoracic surgical unit at Harefield with good results.



Essentially, the instrument consists of a cannula into which a large-bore needle is fitted closely enough to avoid leakage of air and yet allowing the needle to slide freely within the cannula. A guiding pin, firmly attached to the shaft of the needle, fits into a slot at the base of the cannula. The slot is arranged in the following way:

1. When the cannula is pushed right home, preparatory to aspiration, the needle point protrudes from its distal end.
2. When the pleural space has been entered, the needle point may be withdrawn into the cannula, and a small side extension of the slot allows the needle to become locked in this position.
3. If necessary—e.g., for cleaning—the needle can be removed from the cannula.

The advantages of this needle are as follows:

1. Once it is in the pleural space, the needle point can b withdrawn into the cannula, thus considerably reducin the likelihood of trauma to the lung.
2. The cannula protects the point of the needle when not i use, particularly when it is being boiled.
3. The incorporation of the two-way tap reduces th possibility of an air leak at the junction.

The only disadvantage appears to be the size of the needle, which is necessarily large, though not unduly so.

I wish to thank Mr. E. Blackburn, of Chas. F. Thackray Ltd., for his assistance and advice on the manufacture o the instrument.

E. V. MEDILL, M.R.C.S.

Harefield County Hospital, Middlesex.

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis, while its antispasmodic action appears to be largely the result of the bronchodilatation induced by the drug.

IN TABLETS FOR ORAL USE, AMPOULES AND SUPPOSITORIES

MANUFACTURED BY

WHIFFEN & SONS LTD • CARNWATH ROAD
FULHAM • LONDON • S.W.6

'SVC' Trade Mark Brand **Acetarsol Vaginal Compound**

M&B

The presence of trichomonads in cases of vaginitis is not always apparent when ordinary methods of examination are employed, but they are so frequently associated with intractable leucorrhoea that the use of 'S.V.C.' may be justified without actual microscopic confirmation.

TECHNIQUE FOR TABLETS

Where there is marked inflammation of the vaginal walls, a preliminary alkaline douche is given followed by the insertion high up into the vaginal fornices of 2 to 4 tablets of 'S.V.C.' At first this should be done twice daily but gradually the insertion of the tablets is reduced in frequency until finally they are given only on the days immediately following the menstrual period.

TECHNIQUE FOR POWDER

The vagina is wiped dry and painted with a 1 per cent. solution of gentian violet. After this has been allowed to dry for a few minutes the contents of a container of 'S.V.C.' powder are blown into the vagina by means of a powerful powder blower the action of which balloons the vagina, allowing the powder to be deposited in every fold and crevice.

Treatment is given daily or every second day. During menstruation twice the amount of powder should be employed. Insufflation is contraindicated during pregnancy.

ELONGATED TABLETS
Bottles of 12 and 25.

POWDER
Containers of 6 x 6 grammes.

STANDARD PRODUCTS in EPILEPSY

'LUMINAL' was the original phenobarbitone. Of prime importance in epilepsy, its value is recognised in many other indications, including neuroses, pruritus, migraine, insomnia.

'PROMINAL' has a fit-reducing effect at least equal to that of 'Luminal,' toxicity is 30% lower and hypnotic effect is minimal. It is particularly indicated in those milder cases where maintenance of "employability" is an important factor.

Supplied in tablets of various dosages.
Literature available upon request.
('Luminal' and 'Prominal' are Trade Marks).

Nuremberg

History, contemporary or otherwise, may be onceived as a series of dramatic and important appenings, such as wars, separated by intervening eriods which are undramatic and unimportant. his way of looking at human affairs is taught in chools because it is easy, and encouraged by newsapers because it is exciting; but it leads to bewildernent when the course of events does not take so imple a form. A different view of history, though it nvolves the acceptance of some painful ideas, will ead to less bewilderment. On this alternative view he movement of individuals and of groups, even ations, is determined not by their intrinsic character but by the field of forces of which they are a part; their individual volition, if it exists at all, is less significant, in the shaping of their destinies, than the total of forces which moves them. The Aristotelian notion that a stone falls because it is in its nature to go towards the earth gave place to Galileo's and Newton's idea that the stone falls because it is influenced by the forces in the field: and in the same way, in human affairs, we must look to the total pattern before we can understand the movement of a part. On this basis one may look on wars and the intervening periods of peace as phases of human adjustment, both having ultimately the same purpose. This purpose is to achieve a situation of looser tension —to redistribute the forces of constructiveness and destructiveness so that eventually a condition of less danger to valued objects may be established. For the preservation of loved persons and loved ideals is central to any rational consideration of human affairs.

The Nuremberg trial of a score of ageing malefactors and the impeachment of a few disgraceful political organisations can be looked at from two quite different angles. The opinion which has been generally expressed is that it represents a stage in the gradual extension of the range of law; it is a demonstration that, even though the resentment of having been dragged into war is still strong, the principles of fair play are dominant in the victors; and even if it sets higher international standards than the victors always themselves observe it is at least a statement of the moral principles to which they aspire—a statement which may be justified by their future behaviour. True though all this may be, however, it is certainly not the whole truth. Perhaps more fundamentally, the Nuremberg trial may also be regarded as a theatre of operations where the victors came together and worked through their states of tension and mistrust. It too is part of the technique of post-war adjustment, and for this reason no less than the other has potential value. Nobody can now assess this value, though it is easy to suffer illusions about it. On the one hand it is reassuring that the governments can treat abominations in international affairs as they treat crimes in their domestic affairs; on the other hand, law-courts however fair, and sentences however just, do more to assuage the ruffled feelings of the community than to remove the cause of crime.

The victorious nations were a team forced together by a common external danger; they were far from being united, and it would be a foolish act of misbelief to imagine that they were. Profoundly conflicting views as to the way social life should be lived are held by the parties to the peacemaking; there is mutual suspicion, mistrust, and hostility—all the more disquieting when the nations are so explosively armed and when the techniques for reducing tension otherwise than by arms are so poorly integrated into the structure of international life. Nevertheless these techniques exist: there are today many theatres of adjustment where stresses of conflict can be worked out, and the various conferences of foreign ministers, Uno, Unesco, and others serve as outlets of aggression and means of acquiring experience of distrusted people. A conference that ends in discord may seem a disaster but may rather be a valuable cathartic; whereas a trial which ends in unanimity may be a soporific. We cannot judge: indeed most of us can now do nothing except observe the course of events. But we shall do more for the cause of constructiveness and cohesion if we try to keep in mind the whole agony of the world than if we dream, or even hope overmuch, that the condemning of conspicuous criminals is a measure of the world's unity.

Our unity as allied nations was greatest when the common foe was pressing hardest. What common enemy threatens us now? None perhaps is greater than despair over the settling of our own internal difficulties, and the weakness of our methods of dealing with tensions within our groups and with our individual disquiet.

Twenty Years of Typhus Research

Those who were young a quarter of a century ago are apt to compare the present age unfavourably with the years which succeeded World War I. Whatever enchantments distance may lend to the political scene there is no doubt that medically we are now far better equipped with knowledge of how to deal with menaces to life and health than we were in the early twenties. This was clearly brought out by Prof. Hermann Mooser[1] in his address to the British-Swiss Medical Conference on progress in typhus research.

Twenty years ago almost all that was known of the rickettsial infections was that typhus was transmitted by lice, a fact discovered by Nicolle, Comte, and Conseil[2] in 1914, and that Rocky Mountain spotted fever and tsutsugamushi disease were distinct specific infections with their own epidemiological peculiarities. Names like tick typhus, Saõ Paulo typhus, summer typhus, pseudotyphus of Delhi, tropical typhus, scrub typhus, shop typhus, Manchurian typhus, and mild endemic typhus were indiscriminately applied to febrile diseases for which no specific classification was available. The first step in resolving this confusion was the differentiation of flea-borne or murine typhus from the epidemic

or louse-borne variety. MOOSER's account of how this was accomplished differs somewhat from that usually accepted. Doubts as to the louse being the sole insect vector of typhus were first raised in 1923 by JOSÉ TERRÉS[3] in Mexico, where the disease had been endemic and occasionally epidemic from shortly after the Spanish conquest. Since the local population was heavily infested with lice it was difficult to disprove the louse transmission theory in Mexico. A series of mild cases, however, was recorded by SINCLAIR and MAXCY,[4] from the American side of the Rio Grande valley, where the rarity of *Pediculus humanus* var. *corporis* made it unlikely that that insect could act as an effective vector. Previously HONE[5] in Australia had observed cases of typhus in Adelaide in 1922 and 1923 among persons handling wheat and other foodstuffs, while WHEATLAND,[6] another Australian, connected his cases of mild typhus with a migration of mice, associated with an epizootic. WHEATLAND went so far as to give the name "mouse fever" to the disease from which his patients suffered, though they all had positive Weil-Felix reactions. In 1924 FLETCHER and LESSLAR[7] had observed in the Federated Malay States cases of what they called tropical typhus where there was no evidence of man-to-man transmission but the possibility of contamination from rats was high. In 1925 MOOSER[8] obtained a strain of typhus in guineapigs inoculated with the blood of a patient from Mexico City; this and subsequent strains produced a scrotal reaction in male guineapigs similar to that observed by NEIL[9] in 1917 in guineapigs injected with the blood of typhus patients in Texas. In smears from the hæmorrhagic tunica vaginalis stained by Giemsa's method, MOOSER[10] for the first time saw cells with the cytoplasm heavily loaded with rickettsiæ, cells which since 1933 have been known as "Mooser cells." Later, in 1928, MAXCY[11] isolated strains from the south-eastern United States which also produced Mooser cells in the tunica vaginalis of male guineapigs. Shortly afterwards DYER and his colleagues[12] brought forward conclusive evidence that the rat flea was a carrier of what is now known as murine typhus, a disease endemic not only in America but in Europe, Asia, and Africa. Investigations on louse-borne epidemic strains soon showed that some of these also produced scrotal reactions in guineapigs, though the lesions were not so frequent or so advanced as with murine strains. MOOSER[13] was therefore led to regard the differences between murine and louse-borne typhus as quantitative rather than qualitative, and to suggest that the classical strain results from the adaptation of the murine strain to the louse-man-louse cycle of transmission. No conclusive evidence, however, has yet been advanced for the soundness of this hypothesis. We are still uncertain how typhus manages to persist for years in a population where no known cases exist. There are three possibilities:—(1) the rat and the rat flea may maintain the infection which periodically becomes converted into the louse-borne form when a patient with murine typhus also harbours lice; (2) the fæces of lice deposited on clothes and furs may retain their activity for many months, a view specially favoured by Polish and German workers; or (3) persons who have had typhus may carry the rickettsiæ in the bone-marrow and may relapse after months or years. ZINSSER,[14] working on Brill's disease in Boston, convinced himself that all cases of that disease were late relapses of a typhus infection acquired many years previously in Eastern Europe, and MOOSER[1] has recently observed a case of classical louse-borne typhus in Zurich in a man who had suffered from typhus in Russia in 1918.

The other typhus-like fevers have now been classified. In the Mediterranean area fièvre boutonneuse has been shown to be related to Rocky Mountain spotted fever, as is the South African tick-borne fever and incidentally that discovered during the war in West Africa. Saõ Paulo typhus is now known to be identical with Rocky Mountain spotted fever. The scrub typhus of India, Malaya, and Java is identical with tsutsugamushi, while the so-called Manchurian typhus turns out to be of the murine type. Recent studies on the tick-borne typhus of North Queensland suggest that it may be related antigenically to the South African form. Great progress has also been made in the production of vaccines, which, if not entirely protective, are sufficient to lessen the severity of the infection. In *p*-aminobenzoic acid a chemotherapeutic remedy of considerable value has been discovered. Finally, there have been developed insecticides, such as D.D.T., whose lethal action on lice was demonstrated by MOOSER[15] as early as September, 1942. The researches of the last twenty years have thus clearly pointed the way to the control and eventual elimination of the rickettsial infections.

Clues to the Anti-anæmic Liver Principle

IT is twenty years since MINOT and MURPHY introduced the liver treatment of pernicious anæmia; and for twenty years biochemists have been striving to find out just what it is in liver that has this anti-anæmic effect. The clinical worker who follows their work[1] will find himself in a world of filtrates, precipitates, extracts, eluates, and dialysates, and may well ask if such a protracted effort in which, from the lack of a satisfactory animal test, every step had to be checked on human beings has been worth while. The answer is that this research has brought progressively more effective materials for the treatment of pernicious and allied anæmias, and has taught us a great deal about the composition of anti-anæmic factors. It has reduced the amount of solid material needed to bring about remission in a patient with pernicious anæmia from several kilogrammes to about 20 mg, and for maintenance in normal health from 400 g. a day to less than 1 mg., and it has replaced the daily "sandwiches" of almost raw liver by an

ramuscular injection of 1 c.cm. once a week or even :o a month.

ɩn 1927 COHN and his co-workers started by :paring a liver extract free from known vitamins; :y eventually obtained a material containing 10·8% :rogen which they thought was a nitrogenous base, t its low nitrogen content excluded purine or rimidine bases. WEST showed that phosphorus-:e fractions were active, and obtained a material ought to be a peptide or diketo-piperazine, and on drolysis was able to identify β-hydroxy-glutamic id among others. In 1935 DAKIN and WEST opted a different technique for fractionating COHN's renteral liver product, using Reinecke acid, and ey obtained a material of which 'Anahæmin' is a pe. Hydrolysis of this product yielded arginine, sine, leucine, a trace of histidine, hydroxyproline, partic and glutamic acids, glycine, and 15% of ninohexose; pyrimidine and purine bases were)sent. Later they obtained active preparations free om aminohexose, and finally concluded that the emopoietic substance in liver was, or was associated ith, a peptide "possessing many, but by no means l, of the properties of an albumose." In 1942 'EST and MOORE, by electrophoretic methods, split p their most active fraction still further into an :tive "slow component" and a practically inactive fast component." A group of Scandinavian workers .ckled the problem by utilising adsorption on char-)al and elution with phenol, and two of them, LALAND ıd KLEM, eventually prepared active fractions 2–0·3 mg. of which corresponded to 100 g. of liver; ıt the technique seemed to spread the anti-anæmic :inciple among different fractions, rather than effect separation. Ten years ago, in Manchester, WILKIN-)N purified still further the Reinecke acid precipitates ıd obtained a material of which 18–36 mg. would :oduce a complete remission of pernicious anæmia—ıe greatest concentration of active material so far otained. In Switzerland, KARRER and his associates, sing an initial acetone extraction, and adsorption on harcoal with phenol elution, prepared materials of milar activity to WILKINSON's. This material was ee from flavine, pterine, and reducing carbohydrates; contained a small amount of sulphur, and yielded mino-acids, including arginine and tyrosine, on ydrolysis. In 1937 SUBBAROW and his colleagues ostulated that the active principle comprised more ıan one factor; they described a primary hæmo-oietic factor and three accessory factors—l-tyrosine, complex purine, and a peptide. The accessory ıctors were inactive by themselves but when com-ıned with the primary factor they gave rise to a ıuch better response than did the primary factor lone. The complex purine was later found to be an npure mixture containing mainly xanthine, but also strongly fluorescent xanthopterin. Attempts to etermine the nature of the primary factor failed, ut its properties suggested a pyridine derivative.

Many other attempts to identify the liver principle ave been made without, on the whole, adding any-hing significant to our knowledge. There is general greement that it is some form of amino-acid com-ination resembling a peptide. Organic chemistry oes not take us further than this point. It is the tage at which the analysis of the pituitary hormones nd insulin have remained for so long. The appearance, during this period of deadlock, of folic acid, a synthetic hæmopoietic substance with the same anti-anæmic effect as liver principle, is a surprise; for folic acid is a pteridyl glutamic acid, and pterines—which are complex pyrimidines—have repeatedly been excluded from the analyses of the liver principle. The manner of folic acid's action has yet to be worked out, but it is likely that it acts, like hæmopoietin, as an enzyme catalysing the reaction by which liver principle is produced in vivo; for it is this enzyme, rather than the liver principle itself, that is deficient in human pernicious anæmia. The action of folic acid was demonstrated in the course of researches into the activity as growth factors of the vitamin-B complex in bacterial metabolism; and its discovery once again illustrates the occasional startling advances gained by indirect approach when the direct method is gravelled.

Annotations

THREE IN ONE?

IN announcing the establishment of a new Ministry of Defence[1] the Government say that the possible advantages of combining the medical (and certain other) services of the Navy, Army, and Air Force—perhaps under the direct administration of the Defence Minister—are now being studied. This is welcome news, for, as we lately indicated,[2] amalgamation would reduce the number of doctors needed by the Forces both in peace and in war. Examples of redundancy in the triple system both here and overseas are fresh in the minds of those who served in the late war; and the wastage impressed even more forcibly the hard-worked civilian doctor.

The medical service must be (1) reasonably economical in money and men, (2) efficient and readily available to all, (3) flexible enough to fit in with administrative and operational needs, and (4) capable of rapid expansion in war. The efficiency of a unified service would, as now, depend chiefly on the men operating it, but also on the administration and leadership. Plainly, the enlistment of able men is of the first importance. One consideration that has often deterred keen young doctors from finding a career in the Forces has been the comparative dearth of clinical experience—a disadvantage which, in a unified service, might be partly offset by the chance of working, in turn, with each of the three Fighting Forces, in which everyday medical practice differs, even in peace-time. No doubt, too, men could be attracted by a further increase in the establishment of senior clinicians; a perennial grouse against all three Services has been the scarcity of senior clinical appointments; and many have rejected a Service career knowing that when they reach a certain rank they will go no further unless they abandon clinical medicine for an administrative post. Nevertheless the importance of administration should not be decried—especially in a single medical organisation where precise inter-Service coördination would be a first essential. In war, not only must the medical service be rapidly expanded but in all probability it must also be temporarily broken up into constituent parts, some of which will come under the operational control of field commanders. These parts must be swiftly and smoothly formed, and, once separated, must be well administered; and this calls for the training and maintenance of a corps of administrators out of all proportion to peace-time needs. One of the difficulties that may be set against a single service is the restriction it would impose on the training of this reserve of administrators. Lay administrative officers were employed to some extent in the late war; the Army, for example, appointed non-medical stretcher-bearer officers, company officers, registrars, and deputy assistant directors of medical services who acquitted themselves with distinction. No doubt the still wider use of laymen will be considered when the reserve of administrators is in the making.

---

[1] Central Organisation for Defence. Cmd. 6923. H.M. Stationery Office. Pp. 12. 2d.

[2] *Lancet*, Sept. 21, p. 421.

A unified service can be evolved and operated only by the closest understanding between representatives of the clinicians, the medical administrators, and the combatant arms of the Fighting Services; and the Ministry of Defence might well decide to set up a permanent council of this constitution. The difficulties should not be under-emphasised; but given good will in planning, and efficiency in execution, the scheme could benefit all three Services and enhance Britain's already notable reputation in Service medicine.

NICOTINIC ACID IN HYPOMENORRHŒA

EXPERIMENTAL results from Australia suggest that nicotinic acid may be usefully employed in amenorrhœa, hypomenorrhœa, and dysmenorrhœa. Hawker[1] found that the ovaries of guineapigs which had been given nicotinic acid in their feeds weighed 44·5 mg. on the average, whereas the average weight in the untreated animals was 36·5 mg. The application of nicotinic acid to functional disorders of menstruation first suggested itself when a patient who was under treatment with nicotinic acid for a chronic inflammatory lesion at the corners of her mouth started to menstruate, although she had never done so before; in addition, she lost 18 lb. in weight in four months, having previously been inclined to obesity. She was given 75 mg. of nicotinic acid a day for seven months and has menstruated regularly ever since. For the treatment of hypomenorrhœa Hawker suggests the coincident use of stilbœstrol 1 mg. three times a day for fourteen days from the commencement of the period and nicotinic acid 50 mg. three times a day throughout the whole cycle. His nine cases of hypomenorrhœa so treated all showed an increase in the duration and quantity of the flow. The material on which this paper is based is scanty, but it would be foolish to belittle any therapy which may help in these intractable conditions. Further experiments will be needed to discover the exact effect, if any, of nicotinic acid on the ovary; meanwhile, this relatively benign treatment is worth a trial in selected cases.

THE HOSPITAL OF THE FUTURE

EVEN the most modern hospitals nowadays become outdated in the course of twenty or thirty years. The moral seems to be that permanent buildings are not for hospitals: let them rather be transitory, functional, easily assembled, and quickly demolished. That is part of the solution to our present difficulties recommended by Prof. Harry Platt, whose address[2] last year to the Ulster Medical Society has now been reprinted. A rigid pattern of hospital, he holds, tends to determine function, which is fundamentally wrong. Rebuilding every thirty years is out of the question, and remodelling within the shell is a makeshift, not always economical.

The type of hospital in which function is best served, Professor Platt considers, is that in which a number of separate blocks or units, with self-contained ancillary services, each houses one of the major branches of medicine or surgery. These should be placed on an island site with a green belt encircling them, and with space for expansion. Such a multiple-block hospital need not be unsightly: he recalls a fine example of harmonious layout in the University Hospital at Lund, in Sweden, where the separate clinics are Georgian in style, though widely differing in age. In Manchester, his university, the Royal Infirmary, built on the plan in 1908 is already becoming out of date in way as a university teaching hospital, and the ad Eye Hospital, and St. Mary's Hospital for Women Children are both structurally obsolete. There however, a large potential island site of some 100 a visible from the air, which is to be zoned, cleared of dingy property, and dedicated to the purposes of a hospital centre.

In Manchester the separate institutes are to incl university preclinical departments of anatomy, phy logy, and pharmacology; separate units of medic surgery, obstetrics, child health, orthopædics, neurol ophthalmology, otolaryngology, radiology, dermatol an institute for the chronic sick, and a health cent a group of administrative, educational, and resident blocks—including the administrative headquarters the hospital centre, the preliminary training school nurses, students' hostels, residential flats for the and a medical institute and library: Professor P even foreshadows a shopping centre. But the f stage will be what the university architect calls "shack period." The first new block contemplated a neurological institute of 120 beds with both public a private wards and its own outpatient clinic; it w also have its own X-ray department and pathologic laboratories, in both of which research will be und taken. The director, and probably his assistant, w have consulting-rooms in the institute. The princi of the multi-institute hospital could probably be appli Professor Platt thinks, on a miniature scale in small cities.

Building itself is in a state of rapid change at pres and he suggests that it would be profitable to choo and subsidise a hospital architect, and give him five ye to study and travel. Meanwhile hospitals could be mak use of the shack period to concentrate on personnel.

THE BUSY NERVOUS SYSTEM

IT may be possible to predict what will happen wh a known electrical force is released into a known circu but when conditions within the circuit are constant varying, what then? Prof. J. Z. Young, in his inaugu lecture at University College, London, last Febru (now published[1]), described the ceaseless change whi is the normal state of the nervous system, and attack firmly the custom of representing it as a mere telegra system along which messages are transmitted.

We now think of nerve-cells as elongated bags of flu in which compounds are constantly being built up a broken down. And, thanks to studies on the gia nerve-fibres of the squid, we know that the fluid ru the length of the fibres, which therefore have the p perties of cylinders of liquid. They are conductors, b not passive conductors like electric wires; for a ner fibre is made ready to conduct by "the production o state of tension usually referred to as a charge across membrane." The nerve-cell works hard to " the fibre in the right condition to respond to a charge. The various sensory nerve-endings similarly triggered, but not all in the same way— will respond to touch, another to temperature, anot to light, and each must be maintained in the right sta to do its selective work.

The mechanistic theories on which most of us we brought up paid much attention to reflex action, leavi us with a picture of a conducting system which respond in a given way to a given stimulus, but which, in t absence of such stimuli, returned to a state of rest inactivity. This picture, it seems, has had a w influence on our attitudes and behaviour, not only ne and science but in life generally, for it implies oinism. For Professor Young, "this view of the sm as a marionette dancing under the pull of its y impulses is wrong. There are abundant quite e facts which show clearly that the brain is not by neans a passive thing, receiving all its orders from le. Its actions cannot all be adequately described lex, as reflections of outside influence."

[1] Patterns of Substance and Activity in the Nervous S London: H. K. Lewis. 1946. Pp. 19. 1s. 6d.

ysiologists in general, he considers, have not yet nded fully to the facts revealed by the electro-halograph—that there are continuous rhythmical ges of potential between neighbouring parts of the . These are independent of external stimuli: mical activity of the kind continues in the fore- of the frog even in a piece of brain removed from ody. When an image falls on the retina a pattern erve impulses is sent to the cortex of the occipital ; but the cells there are already active, "exciting other or changing their thresholds in manners as unknown." This activity must certainly affect the ion of the brain to the impulses reaching it. In this, els, we may begin to study the problems of recogni- of form and the process of learning. "Remembering" consist in "the maintenance of a particular pattern ode of activity."

this conception of the brain as a continually active it he sees the opportunity for a much more fruitful iboration between anatomy, physiology, neurology, psychology than was possible on the basis of the x concept. To those who think of anatomy as a and-dried subject, which early reached the end of ige of discovery, it will be revealing to learn that hatever part of the body you study you soon find that little is known about it, at least from current points iew." Professor Young wishes to see more than iboration between anatomists and physiologists: ould have a fusion in which those expert in special niques work side by side, remembering that they dealing with "an organised substance in a state of nised and directed activity."

HEPARIN IN INFECTIVE ENDOCARDITIS

HE possibilities of heparin in the treatment of infective ocarditis have been overshadowed by recent spec- ilar successes with penicillin. Although final evalua- is not yet possible, it now seems certain that heparin, sed at all, will be used rarely in this disease. It was employed in the treatment of endocarditis in 1939,[1] it was soon found that its problematical advantages usually outweighed by its proved dangers. When arin was given in conjunction with sulphonamides, recovery-rate—6·5%—was an improvement of only % over results with chemotherapy alone. When it iven with penicillin, hæmorrhagic complications are e common than with penicillin alone, although the overy-rate (55%) remains high; no direct synergism ween heparin and penicillin can be demonstrated.[2] son and Hunter[3] have summarised current opinion oncluding that heparin is not essential to the treat- it of infective endocarditis. They find only two cations for its use: to prevent retrograde intra- cular clotting where a large embolus lodges in a vessel; to inhibit thrombosis when penicillin is given intra- ously. The latter indication is now rarely encountered e the intravenous route has been virtually abandoned avour of intramuscular injection, which gives equally d results; moreover, the increased purity of present- penicillin has undoubtedly lessened the risk of avenous clotting. Other workers[4] advise resort to heparin only when the disease has not responded to one course of penicillin, and add: "in such a case we would hope that heparin might cause disintegration of the vegetations and pray that the fragments will not enter the cerebral vessels."

The value of penicillin in infective endocarditis has now been firmly established in this country.[5] The principal points which suggest that the drug is likely to fail are congestive failure, particularly when the aortic valve is infected; embolic incidents; and a long history. Where the condition has existed for more than a few months there is increased resistance to the penetration of penicillin according to the size of the vegetations and the fibrin and platelet barrier with which they are covered. Necropsies have not provided histological proof that anticoagulants influence the course of the disease under such circumstances[6]; nevertheless, the bad prognosis in these resistant cases may still tempt physicians to give heparin a further trial on the score that nothing can be lost by heroic measures.

SUPPLIES OF ARTIFICIAL RADIOACTIVE SUBSTANCES

THE Government is to establish a national centre for the processing and distribution of radium, radon, and artificial radioactive substances for scientific, medical, and industrial purposes. The centre will be operated by Thorium Ltd., acting as agents for the Ministry of Supply, and as a first step the Ministry will purchase its buildings and plant at Amersham, Bucks. The extraction of radon, which during the war was carried on at Barton-in-the-Clay under the auspices of the Medical Research Council, will be transferred to the new centre, and Johnson Matthey & Co., Ltd., are voluntarily handing over to it their business of filling radium into containers. The Amersham site will not be large enough to accommodate the centre permanently, so it will be removed to new premises when the shortage of building labour has eased and the volume and scale of its work can be assessed more clearly. The centre will be controlled by a council, which will include representatives of the Ministry of Supply, the managing agents, and users of its products.

In the United States the distribution of radioisotopes prepared at the Clinton Laboratories, Oak Ridge, Tennessee, began in August, the first recipient being the Barnard Free Skin and Cancer Hospital of St. Louis, which received a so-called unit of carbon 14 (C^{14}) weighing about one ten-thousandth of an ounce. The unit has a radioactivity equal to that of 1 millicurie, and, since future investigators with radioisotopes will often refer to the actual emission of the substances they are using, it may be recalled that 1 millicurie emits 37 million alpha particles per second. It is understood that activities will be referred to in terms of the curie or millicurie rather than to radium; the C^{14} unit cost the hospital about $400, which can be reckoned a permanent investment, seeing that the half-life of C^{14} is estimated to be between 10,000 and 25,000 years. It is to be used for studying the processes by which cancer is produced. The investigations planned[1] will tackle such diverse medical problems as the mechanism of cancer production, the utilisation of sugar in diabetes, the dysfunction of the thyroid gland, the growth and composition of tooth and bone, and the rôle of iron in anæmia. Outside the fields of medicine the various new isotopes will be applied to problems in agriculture and industry; the outstanding agricultural problem to be studied is the mechanism by which plants utilise the energy of sunlight. Most of the subjects for study are not essentially new, but the method of approach may be said to be so, for the investigators aim at following processes step by step, any faltering being signalled to the observer by the Geiger counters in circuit.

ANTICOAGULANTS IN CORONARY THROMBOSIS

EMBOLI and thromboses in various parts of the arterial system are recognised complications of coronary thrombosis, occurring in 14% of Blumer's 1000 cases,[1] and in 18 of the 100 cases reported by Nay and Barnes.[2] These complications have usually been attributed to narrowing of the arterial lumen and stasis in the blood-flow, but Peters and colleagues[3] have noted that in three-quarters of their patients with coronary thrombosis there was an increased prothrombin activity. This observation is in agreement with de Takats's[4] observation that patients with coronary thrombosis show an increased resistance to heparin.

In view of Solandt and Best's evidence[5] that myocardial infarction and thrombus formation in the coronary tree can be prevented by the administration of heparin, it was only natural that physicians should consider its clinical application. There are difficulties and even dangers in this use of heparin; but the introduction of dicoumarol by Link and his colleagues[6] gave fresh impetus to the study, and several reports have recently appeared in American journals.[3] [7] Peters and his associates have used dicoumarol in a series of 50 patients with coronary thrombosis, among whom the incidence of clinical embolism was 2%, as against 16% in a control group. The mortality-rate in the dicoumarol group was 4%, compared with 20% in the untreated group. Although dicoumarol was given for at least six weeks and sometimes much longer, no serious toxic effects and no frank hæmorrhages were noted; but in three patients microscopic hæmaturia was found. It is emphasised that this treatment should be given only when there is a laboratory for the estimation of the prothrombin clotting-time. Definite contra-indications are hepatic disease and any blood dyscrasia. Special care must be exercised in the presence of hypertension, and the dicoumarol-like action of salicylates[8] and quinine[9] must be borne in mind. Dosage was determined entirely by the prothrombin clotting-time of diluted plasma (12·5%), for which the normal is 85–100 seconds. The usual dose is 300 mg., which can be repeated daily unless the prothrombin clotting-time of 12·5% plasma reaches 400 seconds, which is the upper limit of safety. Hæmorrhage, should it occur, can be controlled by the intravenous administration of menadione bisulphite 37·5 mg. The scheme is very similar to that of Wright,[7] who uses the prothrombin time of undiluted plasma as his guide: the normal figure here is 13–17 seconds, and dicoumarol was discontinued if the time exceeded 30 seconds. Wright's report is only a preliminary one; but, considering that most of his patients were selected for treatment because of repeated episodes of multiple thrombi or repeated embolic phenomena elsewhere in the arterial tree, his results are certainly encouraging. Of 43 patients selected because of complications known to be associated with a very high mortality-rate, only 11 (25%) died, compared with an anticipated risk of 60–70%; while of 33 patients having their first or second uncomplicated attack of coronary thrombosis, 4 (12%) died, compared with an anticipated mortality of 20–30%.

Two further aspects are worth considering. It has been confirmed by Peters and his co-workers that one risk in using digitalis for the heart-failure of thrombosis is its tendency to increase the clott of the blood.[10] Does dicoumarol neutralise this Scherf and Schlachman[11] found that the p time and the plasma coagulation time are after the intravenous administration of the with ethylenediamine, and also of theophylline acetate. A similar effect was obtained by the administration of the methylxanthines (theoph with ethylene diamine, theobromine, and theob sodium acetate). This is not a new observation of the earlier German workers actually reco theophylline with ethylenediamine as a coagulant, Wright gave it as part of his "conventional tr to patients receiving dicoumarol); but it suggests a careful review of our treatment of coronary throm is called for. Until much fuller data are dicoumarol should clearly be used only in sele cases treated in hospitals.

SIXTH AND LAST

THE final issue of the sixth volume of the *Bulleti War Medicine* contains two epilogues which mark end of this publication. The first, by Sir Edw Mellanby, F.R.S., secretary of the Medical Resea Council, recounts briefly the history of its inception, second, by Dr. Charles Wilcocks, director of the Bur of Hygiene and Tropical Diseases, acknowledges services of all those whose work contributed to the v of the *Bulletin*. Together, these epilogues reflect a fru collaboration between the Medical Research Council its publications officer, the bureau, and the large num of abstracters who devoted part of their meagre le to the task of providing medical information for th who otherwise might have missed it. Though immediate purpose of the *Bulletin* has now been ser the medical historians of the war will find in it m of the material they may need for describing the deve ments of that period of—in some directions—phenome progress. The rapid growth of knowledge in relatio transfusion, penicillin, D.D.T., and mepacrine, for instan is reflected in these abstracts.

The enormous importance of diseases (especi tropical diseases) in military campaigns has reaffirmed during the war, when the success of operat turned on the maintenance of forces healthy enoug undertake them. That many of the problems invol were quickly solved was largely due to the stim given to research by the urgency of the situation. the same or similar problems persist among the indige inhabitants of these tropical countries, and we hope that research will be pursued as vigorously peace as for war. There is still, therefore, the same for information on tropical diseases and on public-he measures, and this will continue to be supplied by bureau in its two publications, the *Tropical Dis Bulletin* and the *Bulletin of Hygiene*, which wer existence long before the war, and which were the m on which the *Bulletin of War Medicine* was based.

A MEETING has been arranged at the London Scho Hygiene, Keppel Street, London, W.C.1, for Thur Oct. 17, at 3.30 P.M., with the object of inaugurati council for the care of spastic children. The chair wil taken by Mr. G. R. Girdlestone, F.R.C.S. The ac secretary is Mr. H. P. Weston, c/o Council for the Car Cripples, 34, Eccleston Square, S.W.1.

WE regret to record that Lieut.-Colonel R. J. THOMPSON, who retired from the secretaryship St. Thomas's Hospital medical school last month, die Oct. 2. He was 60 years of age.

TUBERCULOSIS IN POLAND

MARC DANIELS
M.D. Paris, L.R.C.P.E., D.P.H.
MEDICAL OFFICER, HEALTH DIVISION, UNRRA

is report is based on information collected during weeks' tour of the Polish tuberculosis services. ing the areas of eleven of the sixteen regional orities, and including personal visits to twenty- e sanatoria and numerous hospitals and dispensaries. discussions with doctors in these places, in provincial th offices, and at the ministry of health.

ne situation, a tragic one, must be set against the ground of war-time and post-war Poland. The years' occupation of Poland was so grim that the ple must be considered primarily as survivors of occupation. Almost every Pole has lost relations home, has starved, or has lived in unimaginable ditions. Very many can roll up a sleeve and show centration-camp numbers tattooed on their arm.

he Germans set about systematic extermination of llectuals and professional people, with the object of ucing Poles to the level of slaves. Leading medical cialists were taken from the wards and shot in their es or against a street wall. Their equipment and aratus for research was stolen or deliberately troyed, as were their documents representing many rs of valuable work. Of the 12,900 doctors in 1939 6000 are left. In a rural area we gave a lift to a ntry doctor; he is sole doctor for an area with 00 people and has no car. Nurses also are very ce; *half of them were killed during the war.*

he devastation of Warsaw, Poznan, and Wroclaw ndescribable. Warsaw was destroyed systematically, se by house, street by street. In the shambles t remain live half a million people. Among this ulation living in dark cellars and one-room flats ch by a miracle retain four walls and a ceiling there several thousand cases of tuberculosis. Overcrowding shortage of food provide all the tubercle bacillus uires in order to flourish. In devastated rural areas ilies are living in dugouts and mud huts. Millions of s are still lying fallow for lack of seed, equipment, abour. Some areas have yet to be cleared of mines; sants *impatient to plough their land are sometimes wn to pieces.*

o the rural areas are returning peasants and children peasants who were taken off for slave labour in many. Many contracted tuberculosis there and, rning home, are spreading infection. Millions of the ple are, or have recently been, on the move. They rn from camps for displaced persons in Germany, n the armies, from Russia. Large communities being transferred from the old eastern provinces to newly acquired western provinces. People who ght refuge in the country during the war are trying eturn to the city, even to Warsaw.

gainst this background of devastation and potential os reconstruction is going on. Some of the work escribed in this report. In assessing the services and k done to date, the background must not be forgotten. e work of public-health officers with no records, of fessors of medicine with no clinics, of scientists with laboratory or equipment in Poland needs to be seen be believed.

MORTALITY

There has been an alarming increase of tuberculosis Poland during the war years; and the disease is now lespread. Destruction of all pre-war records by the rmans renders detailed comparisons impossible. During the war only such services were allowed to function as would protect the Germans from danger of infection, and public-health services worked on a very reduced scale. Towards the end of the war, during the retreat, there was wilful destruction of public buildings and records. At present the services are being restored, but records are still very limited and fragmentary, since new workers are being trained to replace the many thousands killed and executed, and many new workers are still inexperienced and overworked. In view of these limitations, statistical information has been considered carefully, and only that considered valid after personal discussion with the health authorities is given here. The only figures of value come from large towns. Death certificates outside towns may be given by non-medical persons and are for statistical purposes valueless.

Warsaw.—The number of deaths from tuberculosis per 100,000, already high before the war, rose 200% in the war years, from 155 to 452 in 1941 and 500 in 1944. Before the war the rate was four times as high as in U.S.A. (white population): in 1944 it was fifteen times as high. The tuberculosis mortality in Warsaw and Lodz, compared with that in U.S.A., Copenhagen, and Stockholm, was as follows:

	1935	*1941*	*1944*
Warsaw	155	452	500
Lodz: All persons	176	316	371
Germans	..	139	155
Poles	..	378	461
U.S.A. (whites)	39	35	34
New York (all persons)	..	46	48
Copenhagen	51	44	40
Stockholm	92	75	70

In 1945 the registered tuberculosis deaths in Warsaw totalled 1189, which figure for a population of 400,000 gives a death-rate of 297. It must be remembered, however, that in that year, after the destruction of the city, the population numbered only a few thousands in January, and former inhabitants returned during and after liberation, to reach a total of nearly half a million only at the end of the year. If a mid-year population figure were available, the rate on this basis would be much higher than 297.

The recent census has shown that the proportion of young adults in Warsaw has fallen to an abnormally low level, owing to killing and deportation of all active members of the community; the *population age-distribution curve* shows a well-marked dip between the ages of 15 and 30. An adjustment of the death-rate to take into account the absence of this most susceptible age-group would have the effect of raising the rate considerably.

In Jews the death-rate before the war was relatively low, about 80. In 1941 it had risen to 440.

Lodz.—Here the mortality rose from 176 before the war to 401 in 1943, dropping later to 371 in 1944 and 288 in 1945. The war-time rates relate to the combined German and Polish population. For the Poles alone, the figure was 488 in 1943 and 461 in 1944, while in Germans the death-rate was only a third of that in the Poles (see fig. 1).

Poznan.—Mortality rose from 198 before the war to 360 at the end of the war.

Krakow.—In 1945 there were 615 deaths from tuberculosis in a population of 221,260, a death-rate of 278.

INCIDENCE

Mass Radiography Surveys.—This is the most valuable method of determining incidence of *pulmonary* tuberculosis in large communities. Several such surveys have been made in Poland since the end of the war. There are no *similar results* covering the pre-war period, but these recent figures are very striking.

(1) At Krakow University 9387 students have been examined by mass radiography in 1945–46, with the result that 392 (4·2%) are found to have tuberculous lesions considered active, and 623 (6·6%) tuberculous lesions requiring observation, making a total of 10·8% who require treatment or observation.

(2) In the Poznan surveys of 1945–46 7% of 4000 university students, 6·5% of 201 high-school students, 7·1% of 463 school-children, and 13·5% of 1361 factory employees have been found to have tuberculous lesions requiring treatment or observation.

(3) A Swedish Relief Service team is examining students in Warsaw. Provisional results, for 2000 students, indicate that over 15% have pulmonary tuberculosis *requiring treatment or observation.*

(4) During the occupation 1941–44, of 180,000 railway employees examined by the social-insurance organisation 7% were found to have pulmonary tuberculosis requiring treatment and 5% required observation.

Mass Radioscopy Surveys.—Of 4220 Lodz high-school and university students examined 5·8% have tuberculous lesions requiring treatment or observation; and of 1500 Lublin university students examined 2·1% have tuberculous lesions requiring treatment and 9·7% have tuberculous lesions requiring observation. These figures of the results of mass X-ray *examinations are approximately ten times as high as corresponding* figures in England (fig. 2) or the U.S.A. They confirm the impression given by the very high mortality in large towns of Poland.

Known Clinical Cases.—The figures given above indicate the prevalence of undiagnosed tuberculosis in the general population. They do not include the known cases, diagnosed by ordinary clinical methods. Tuberculosis is not notifiable in Poland; but some information is provided by the numbers of patients attending tuber*culosis dispensaries. In Upper Silesia, in a population of* 1,600,000, there are over 16,000 cases (1%) known to the tuberculosis clinics. In Poznan, a city of 283,000 inhabitants, there are 3293 (1·2%) cases known to the city dispensary. In the town of Zgierz 1·7% of the population are known to be tuberculous and requiring treatment. These figures are high, compared with similar figures in U.S.A. and Great Britain. Moreover it must be emphasised that not all cases are reported to the tuberculosis clinics; the figure, therefore, falls far short of the total of diagnosed cases.

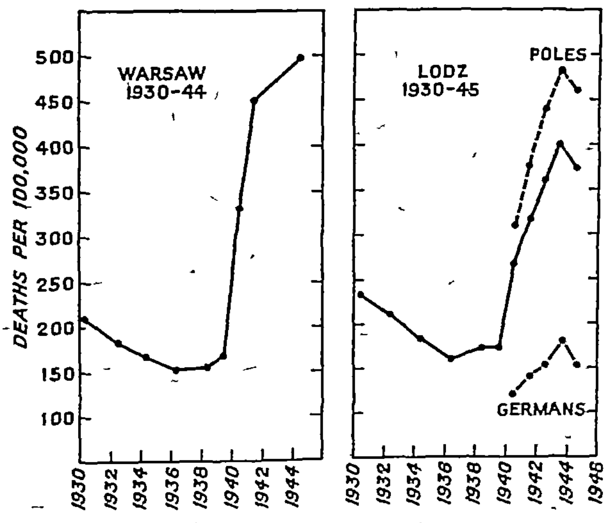

Fig. 1—Tuberculosis mortality in Warsaw and Lodz.

TUBERCULOSIS SERVICES.

After 1918, legislation placed the onus for
and *maintaining* dispensaries, tuberculosis
sanatoria on the smaller local authorities—
communes—empowering them to unite to form
schemes. The province (vaivodeship) was to
an overall responsibility of directing the small
authority regarding when and where such services
be established. General control was exercised by
department of health of the ministry of labour
social welfare. Educational and propaganda
was conducted largely by the National Anti-Tub
Association.

The *main* work *of the services* was conducted
tuberculosis dispensaries, which numbered 532 in
Of these, 436 were in health centres administered
by the local authority and providing diagnostic
treatment facilities for venereal diseases,
tuberculosis, and incorporating also maternity
child-welfare services. They were staffed by d
who usually also carried on private practice and
for social-insurance and other organisations. The
insurance body also conducted a few tuberc
dispensaries independently.

In 1938 there were 2680 beds for tuberculosis i
general hospitals and 5638 in 45 sanatoria. O
of the sanatoria belonged to local authorities; the
were owned by the social-insurance organisation,
bodies, Polish Red Cross, and professional and
tional associations. There was no central or
control or planning of the institutions.

Payment for hospital and sanatorium treatment
the responsibility of district local authorities in all
not covered by such organisations as social insur
Local-authority funds being very limited, this mea
practice that institutional treatment could be
to only a very small proportion of those unprotecte
insurance or private income.

At the present time general control is exercised b
tuberculosis control section of the newly created *min*
of health; the section is directed by Dr. Tel
Regional health control is exercised through the

of Warsaw and Lodz. The tuberculosis subco
of the National Health Council acts as an advisory
The Anti-Tuberculosis *Association* is being reconstit

Dispensary Service.—The services, which suffered
losses during the war, are being reorganised with mo
less the same general structure, and the same un
division of financial responsibilities. Dispensaries, ma
of which ceased to function during the war, and wh
in any case were allowed to serve only as diagno
centres without being able to provide or arrange for tre
ment, are now being rapidly restored; 440 are oper
at present, nearly all within health centres. There is
serious lack of equipment, X-ray units especially,
a great shortage of doctors and nurses, particularly
specialised personnel. The doctors at these

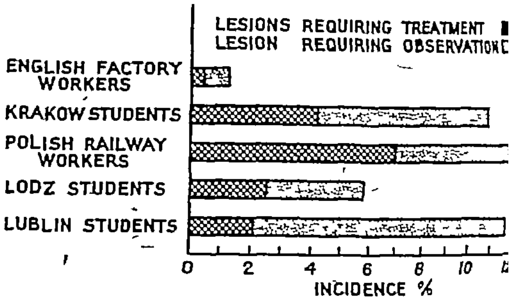

Fig. 2—Incidence of tuberculosis found by mass X-ray survey

y all of them doing this service in addition to busy te practice, are doing a heavy job of work. Rela- y few of them have any particular training in tuber- sis. In the province of Kielce, for instance, for -five dispensaries there are forty-five doctors, four of whom have special qualifications. The ensary service, main prop of the tuberculosis organi- on, is for the most part staffed by unspecialised per- nel provided with a bare minimum of equipment, and ggling with an ever-increasing tide of tuberculous ients. The chief tuberculosis officer (also part-time) the provincial health department has very little hority either over the dispensary service or over the atoria.

ase-finding Surveys.—Several case-finding schemes under way; the results of some of these have en given. There are seven photofluorographic units, ated as follows:

n Warsaw, in op.,	70 mm., Swedish Relief Service.	
n Krakow, ,,	35 mm.	Belongs to social-insurance organisation.
n Poznan, ,,	35 mm.	
n Poznan, not in op., lens missing		
n Bydgoszcz, ,,	,,	Belongs to dispensary service
n Katowice, ,,	awaiting film	

The main universities have an excellent diagnostic rvice for their students resumed on the same basis before the war. There is also a very fine students' natorium, probably the first to have been founded in rope (inaugurated in 1907).

Hospital and Sanatorium Services.—A complete picture these services cannot be given at present, as the uation changes from day to day; only information llected quite recently is presented.

In general hospitals, out of a total of 86,000 beds, 00 are set aside for the treatment of tuberculosis.

During the six years of war all the sanatoria except e were occupied by the Germans. Towards the end the war, as the Germans retreated, they destroyed, oted, and burnt many of the buildings, stripping them all equipment. This was the situation the Poles faced year ago: a country which had been without sanatorium cilities for its tuberculosis population for six years, natoria destroyed, sanatoria with no beds, no equip- ent, and no staff. During the past year people have en occupied with the enormous task of restoring these natoria within the Polish tuberculosis services. Almost e whole time, for instance, of the director of the udents' sanatorium in Zakopane is taken up by problems rebuilding and by search for equipment, instruments, d drugs. This search, in a country plundered stematically during the war, is no easy task. Principal ems lacking are thoracoscopes, replacement bulbs for oracoscopes, surgical sets for thoracoplasty, X-ray m, developer, and fixer, X-ray tubes, needles, plaster, boratory reagents, and narcotics.

In spite of lack of material the sanatoria are being stored very rapidly. Much equipment has been ceived from UNRRA. There is now more sanatorium commodation than before the war, thanks to the quisition of previously German institutions in Lower lesia. There are 11,580 "potential" sanatorium beds. description of the situation in Southern Poland, where ost of the best sanatoria stand, will help to explain hat this "potential" figure means at present.

In Lower and Upper Silesia and in Zakopane there are xteen sanatoria with a possible total of 6078 beds: 301 are not yet ready (equipment lacking, premises not ompleted); 1840 are still requisitioned by armed rces; and 2937 are available for tuberculous patients. f the 2937 available beds 1905 are occupied by patients of whom 237 are German) and 1032 are empty.

The 2937 beds are in excellent sanatoria, equipped for ctive treatment of tuberculosis and staffed by competent octors. Yet 1032 stand empty. The main reason for his lies in the financial difficulties of the health authorities responsible. For some patients cost of hospital treatment may be covered by an insurance organisation, the Polish Red Cross, or the ministry of health, which assumes responsibility for treatment of repatriates. A few persons may bear the cost privately. But the majority have no protection of any kind, and for them the small local authorities are theoretically responsible for provision of treatment for tuberculosis. In fact, with the present high cost of maintenance in institutions, 100–200 zlotys a day, and with few local taxes collectable, most authorities can only afford to maintain very few patients in hospital or sanatoria. Most of their patients, when they do go, are sent only for a short time. From Lublin city dispensary for instance, where 1211 new cases were diagnosed in 1945, only 99 patients were sent to hospital (for an average interval of three weeks) and 9 to sanatoria. This dispensary has a waiting-list of 646 persons. Bydgoszcz provincial authority has a good sanatorium at Smukala, with 124 beds, yet of the 360 new tuberculous patients diagnosed in the first three months of this year none could be sent to sanatoria.

The ministry of health is able to pay for only 1000 patients for the whole country, and these include repatriates. For patients unprotected by insurance, private income, or otherwise, there is little hope of any treatment other than two weeks in the local hospital for induction of pneumothorax when this is thought advisable; they are then sent home again. These patients are the ones in the worst economic condition; it is not difficult to imagine the prognosis for such patients, and the risks for their families. Even for insured patients, the limit of stay in sanatoria is usually three months.

On the basis of an overall tuberculosis death-rate of 300 per 100,000, and setting the minimal standard of 100 beds against every 100 deaths, there should be at least 66,000 beds. There are only 11,580; and, though half of these are not ready or are still requisitioned, there are still many beds standing empty because no one can bear the cost.

The main cost is food. Sanatoria are obliged to buy most of their food in the open market. The cost of food varies from one province to another. In one, 100 zl. may cover a relatively adequate diet of about 3000 calories (with too high a proportion of carbohydrate); in Lower Silesia 150 zl. may provide only a diet well below the minimal requirements for a healthy person. For example, in Zeylandowo, patients receive a small portion of meat or fish twice a week, no cheese, and no butter. For three months they had no milk except in soup, now they have 0·25 litre a day. Nurses are constantly leaving because of the bad diet, since they have the same as patients but minus the milk. In one sanatorium, arriving at 1 P.M., we partook of the main meal; it consisted of a thin vegetable soup and a plate of rice.

In several institutions the diet is not more than 2000 calories. From Kamieniegura sanatorium we brought away a complete list of all foods consumed during March by the 400 persons in the sanatorium. An analysis on the basis of figures given by the M.R.C. Memorandum (no. 14, 1945) on "Nutritive value of war-time foods" shows that the average daily diet per person in this sanatorium amounted to 1995 calories, with 348 g. of carbohydrate, 37 g. of fat, and 67 g. of protein (of which 23 g. was animal protein).

Thus the problem of food not only affects the condition of patients in sanatoria but also is indirectly responsible for many beds standing empty. UNRRA is committed to a programme of provision of food to the whole Polish people through the central government and cannot undertake specific allocation and distribution; but any assistance that could be given in provision of food to the sanatoria would go a long way to the solution of their problems.

Staffing of Services.—Reference has already been made to the severe shortage of doctors and nurses. There is an average of one doctor for 3600 people, and one nurse for 7000 people. We met a woman doctor running a health centre who works there all day, has no nurse to help her, and is so overworked that she has no time to keep any record of patients. In her district previously there were 72 doctors; now there are only 10. In the sanatoria there are for 100 patients usually 4 qualified nurses, this number including both day and night nurses. In one sanatorium for 275 patients there are 5 nurses. Many dispensary nurses have no time to do any health visiting.

The lack of specialised personnel is particularly great, as a relatively high proportion of these were killed. The chief thoracic surgeon for Warsaw was shot by the Germans. There are now in Poland only two surgeons specialising in chest surgery.

Courses are being arranged for doctors; they are planned as intensive courses lasting two or three months and will be given in the principal university centres. Grave difficulties are arising in this connexion. Owing partly to economic difficulties of doctors, and partly to the fact that a country doctor can find no locum to replace him even for a few weeks, there are very few candidates, though the ministry is offering maintenance and 8000 zl. a month to those attending the course.

In Poland, as throughout the rest of liberated Europe, a constant cry is the need for medical literature covering the war period. In addition, Poland suffered complete and wanton destruction of many medical libraries, public and private, so that she has lost also much valuable medical literature from before 1939.

CONCLUSIONS

The incidence of tuberculosis in Poland is now alarmingly high. Involving usually chronic disease over many years, and affecting mainly adolescents and young adults, it causes an immense wastage of human life. Of the toll on health taken by the war and the German occupation, it is by far the most serious disease, and will continue to be so for many years to come. The fact that it is not an acute epidemic disease renders less apparent the need for an intensive campaign; the need, however, is urgent.

Great progress has been made in re-establishment and re-equipment of the services. But these services started almost from zero after liberation a year ago; equipment is still in very short supply, and organisation is still defective. The situation is such that it must be regarded as nothing less than a national emergency. Recommendations have been made for an emergency supply programme and for urgent reorganisation along lines practicable under present conditions.

The task that lies before the ministry of health is no mean one; it is that of planning tuberculosis control in a country which has been systematically devastated, which has a very high incidence of tuberculosis, which lacks equipment, doctors, nurses, and trained administrators, and which must concentrate its economy mainly on reconstruction. In a five-year programme far more equipment will be required, particularly for the establishment of tuberculosis hospitals to raise the total to 30,000 beds. Radical reorganisation will be necessary if the service is to be well staffed and to come within a single national plan of attack on tuberculosis. A much greater proportion of the national budget will have to be devoted to the anti-tuberculosis campaign (before the war the proportion was exceptionally low).

Only after the initiation of such a programme, and after a raising of the living standard, which will of necessity be slow, can any important and continuous decline in this disease be expected in Poland. Further, though much will depend on the Polish people themselves, war-time devastation has been such that assistance from without will be needed for a long time and on a generous scale.

INTERNATIONAL SOCIETY OF HYDROLOGY

THE first post-war annual meeting of the was held at Buxton from Oct. 4 to 6. The representatives from abroad were: Belgium, Michez (Brussels); Czechoslovakia, Prof. F. (Prague); France, Dr. P. Petit (Royat); Dr. J. van Breemen; Switzerland, Dr. V. Ott (U.S.A., Dr. Loring Swaim. The following officers elected for 1946–47: president, Lord Horder; of council, Dr. J. B. Burt; vice-chairman, Dr. G. Kersley; hon. treasurer, Dr. Frank Clayton; secretaries, Prof. František Lenoch and Dr. D Wilson; 39 new members and 5 associate were elected. Arrangements for renewing the tion of the society's journal were discussed.

In his presidential address, Lord Horder, one of two surviving founder members of the society, emph sised the great part which would be played in restoration of international relations by free of medical men of different countries for discussion common problems.

Dr. J. van Breemen discussed the four causal facto in rheumatic disease—focal or other infection; con stitutional anomalies; *abnormalities of the peripher* circulation and in the defence mechanism of the skin and social and environmental influences—in relation medical hydrology.

Dr. V. Ott described research work done in Switzerlan in testing the effects of thermal treatment on the auto nomic nervous system.

Dr. Abraham Cohen, of the Philadelphia Gener Hospital, gave an account of the use made in his hospita of physostigmine in the relaxation of muscle spasm He referred to the experience of other workers wit '*Prostigmin*' but maintained that physostigmine sal cylate was equally efficacious, less expensive, and le toxic. The method adopted in the arthritis (inpatien ward was to give all patients injections of isoton saline daily for a week. If these and complete re produced no improvement, hypodermic injections atropine (0·06 mg.) were given daily for the next wee If again there was no improvement, he gave mine and atropine mixed in the same syringe, beginnin with 0·06 mg. of each. The quantities were adjuste according to whether side-effects on the autonom *nervous* system were *produced* by either of the tw drugs. If the physostigmine/atropine balance w correct, the treatment could be administered indefinitel but the usual period was six weeks. The best resul were obtained in rheumatoid arthritis when the spas was very severe. The treatment was not to be regarde in any way as a cure but as an auxiliary method whic might produce considerable amelioration of symptom particularly relief of pain. Among other conditio in which good results had been obtained were spas due to war wounds and other traumata, Felty's syn drome, and paralysis resulting from nerve injuries.

Dr. Loring Swaim discussed American concepts of the treatment of chronic rheumatic diseases, stressing the importance of individual reactions to personal and social environment, and the responsibility of the physicia to reorientate the patient.

Mr. R. B. Whittington (Manchester) discussed correlation between the plasma viscosity of the blo and the erythrocyte-sedimentation rate; he produced evidence of the greater reliability of the former in reflecting the progress of various diseases.

TOWN MEETS COUNTRY

"ONLY when the soil of a country is in good heart and fruitful can the rest of that country's system b in good heart also." In this belief the founders of a new Association of Agriculture seek to engage the interest of the British public in a prosperous countryside, which they regard as necessary "economically, nutritionally and socially." They hope to achieve this object partly by the education of the young, but partly also through the coöperation of medical authorities who can emphasis the need for a national food policy that will enable British agriculture to make its *full contribution.* "A y farming industry is everybody's affair, and every- should realise it."

new association was launched last Monday night Mansion House dinner with the Lord Mayor of on in the chair. Mr. Tom Williams, Minister for ulture, said that only 7% of the population of this try now work directly on the land, and the man g in the heart of urban Britain naturally has more d for the habits of the people among whom he was ght up than for the environment of his great- dfather. Agriculture was now fully recognised as a onal asset, but "town and country must eventually to understand each other's problems."

ord De La Warr, president of the association, said in the past the towns had demanded a rising dard of life at the expense of food-producers both ome and abroad. That scheme of things had broken m between the wars because of the glut which pre- ted food-producers from buying the products of the n, and it had now broken down again for precisely opposite reason. He based the claims of British iculture not so much on good will or gratitude for r services as on the continuing need for food-produc- n at home: why should precious money be sent oad to pay for food that can be grown in this country? eriods of plenty exploited by the consumer, and riods of shortage exploited by the producer, are not ing to lead us anywhere," said Lord De La Warr. was the task of the new association to show that, erever temporary advantage may lie, in the long n the interests of town and country are the same. was not concerned with policy but with education, eking to create the mental background against which licy may be considered. This country should face the ture not as two nations but as one, with equality of ghts and responsibilities.

Colonel Walter Elliot, F.R.C.P., said that as a former inister of Agriculture he shared the uneasiness of the untryside; and when Minister of Health he had been sponsible for inviting over a million women and ildren into the country—thereby introducing the ord "evacuee." He asked the City to consider the eat and steady markets that can be built out of "the ocessing of mud"—a raw material of which, in this untry, there is unlikely to be any shortage.

Mr. Anthony de Rothschild spoke of the need for balanced economy, and Mr. Charles Dukes, president f the Trades Union Congress, said that the Government ust ensure that goods produced under sweated condi- ions shall not unfairly compete with the products of abour on our own soil. Mr. J. Turner, president of the National Farmers' Union, thanked the medical profession or showing that agriculture should produce what is needed by the people rather than what it would like to produce. Agriculture, he said, was now straining at the eash to produce what the country really needs.

The address of the Association of Agriculture, which hopes to receive the widest possible support, is 32, Bedford Square, London, W.C.1.

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED SEPT. 28

Notifications.—Smallpox, 0; scarlet fever, 1001; whooping-cough, 1451; diphtheria, 285; paratyphoid, [illegible]9; typhoid, 12; measles (excluding rubella), 1461; pneumonia (primary or influenzal), 373; cerebrospinal fever, 32; poliomyelitis, 30; polio-encephalitis, 0; encephalitis lethargica, 2; dysentery, 66; puerperal pyrexia, 164; ophthalmia neonatorum, 67. No case of cholera, plague, or typhus was notified during the week.

Deaths.—In 126 great towns there were 2 (0) deaths from enteric fevers, 1 (0) from measles, 1 (0) from scarlet fever, 8 (1) from whooping-cough, 7 (0) from diphtheria, 47 (3) from diarrhœa and enteritis under two years, and 5 (2) from influenza. The figures in parentheses are those for London itself.

Willesden and Swansea each reported 1 death from an enteric fever.

The number of stillbirths notified during the week was 275 (corresponding to a rate of 28 per thousand total births), including 20 in London.

Medicine and the Law

Insanity Moral or Legal

Since the Court of Criminal Appeal was created, an appeal thereto in all cases of conviction of murder has been almost automatic. The judges of that court indeed have sometimes found themselves saying that there is no explanation of a particular appeal except the fact that it is a case of murder. Neville Heath, sentenced to death at the Central Criminal Court on Sept. 26, has furnished an exception to the usual practice. He made no appeal to the Court of Criminal Appeal, but left his case to the medical board which the Home Secretary consults when the defence is insanity. Thus his fate will depend not on the narrow definition of insanity enshrined in the rules in McNaghten's case as long ago as 1843, but upon up-to-date medical opinion informed by all relevant evidence, whether or no the evidence was given at the trial.

Heath was convicted of the murder of Mrs. Margery Gardner at a London hotel on June 21. British justice requires that an accused person be tried for one offence only at one time, lest a jury be tempted to believe that, because he has been guilty of one crime, he is therefore probably guilty of another. Heath, as his counsel conceded, had also murdered Doreen Marshall at Bournemouth on July 4. The worse his conduct, the more material for a plea of insanity. For the defence Mr. J. D. Casswell, K.C., asked the jury to say that Heath was "as mad as a hatter, absolutely insane, a maniac." The conduct of the accused, who suffocated one of his victims, lashed her, and tied her up so that she was helpless, did not (urged counsel) show the premeditation of a sane person: no man in his senses could possibly have done what this man did; it was a case of sudden but latent insanity.

The expert testimony at the trial showed the usual conflict. Called by the defence, Dr. W. H. D. Hubert, psychotherapist at Wormwood Scrubs Prison before the late war, said that the injuries inflicted on the two women were extremely savage, the actions of a sadist. Heath, when visited in prison, appeared to show no remorse or appreciation of what other people would think of his behaviour; after committing these crimes, he behaved in quite a casual manner, considering his intelligence. In the witness's opinion, Heath was not an ordinary sexual pervert, but he suffered from "moral insanity" and at times was quite unaware that what he was doing was wrong; he was certifiable as morally insane. Under cross-examination Dr. Hubert described Heath as a moral defective in law, but, when referred to the statutory definition in the Mental Deficiency Act of 1927, he could point to no evidence of arrested or incomplete development of mind before the age of 18 years. In answer to the Judge, Dr. Hubert said Heath was suffering from a disease of the mind, a general abnormality; he suffered from a defect of reason inasmuch as he was unaware of other people's attitude towards these offences. Prosecuting counsel called Dr. Hugh Grierson and Dr. Hubert Young, senior medical officers at Brixton and Wormwood Scrubs prisons respectively. Neither considered Heath insane; he was a sadist, but sadism is an abnormal exaggeration of a normal instinct of the human race. Neither was prepared to agree that Heath did *not* know that what he was doing was wrong and punishable by law. For the defence it was suggested that these two witnesses were not consultants, had not practised in mental hospitals, and had experience only as prison doctors; they had found Heath repressed, uncommunicative, and uncoöperative because he knew that they were prospective witnesses for the Crown.

Mr. Justice Morris, in summing up to the jury, used the usual judicial definition of insanity. Everyone was presumed to be sane and responsible for his actions until the contrary was proved. Insanity was not established merely by outrageous and unexpected behaviour. This had been described as an instance of "partial" or "moral" insanity or as mental defectiveness. These were not the real issues. The judge emphasised that the jury must consider whether they thought that Heath did or did not know that he was doing what was wrong. It seems to have been upon this issue that he was convicted. The prosecution suggested that in his conversation with Miss Symonds about the crime, in his letter to Superintendent Barratt as to the identity of the criminal, in his change of name (to "Group-Captain Rupert Brooke") when he went to Bournemouth, and in his attempts to conceal the body of Miss Marshall, Heath had been trying to cover his tracks. These matters were among those mentioned by the judge as possibly material to the issue which they were trying. After a retirement of an hour they brought in a verdict of guilty. Heath, when called upon, made no statement and indeed showed indifference and unconcern.

The lay public was probably less interested in the issue of criminal responsibility than in the details of the crime. Heath's past career was narrated by a police witness in answer to questions by Mr. Casswell.

Born in 1917, he had served in the Territorial Army in 1934, and in 1936 had joined the Royal Air Force. He was dismissed by court-martial sentence next year, after trial for absence without leave, for escaping while under arrest, and for unauthorised taking of a motor-car. A month later he was placed on probation for frauds at an hotel and for attempting to obtain a car by false pretences, eight other cases of fraud being taken into consideration. In July, 1938, he was sent to Borstal on charges of stealing jewellery and cheque frauds, ten other cases being taken into consideration. He was released at the outbreak of war, enlisted in the R.A.S.C., and went to the Middle East in 1940 with a commission. In 1941 he was court-martialled and cashiered for frauds as to pay; there were other charges. Sent back to England, he landed improperly at Durban and found his way to Johannesburg where he posed as Captain Selway, M.C., of the Argyll and Sutherland Highlanders. Changing his name to Armstrong, he joined the South African Air Force as a pupil pilot, reached the rank of captain, and in 1944 was seconded to the R.A.F. and took part in operational flying. He had been married in South Africa in 1942; his wife obtained a divorce nine months later but with no suggestion of cruelty or sadism. In December, 1945, he was convicted by general court-martial in South Africa on various charges, including three for wearing decorations without authority. He was then sentenced for the third time to dismissal from the R.A.F. Returning to London last February, he was fined in April at Wimbledon for unlawfully wearing uniform and decorations to which he was not entitled.

How the recital of this record may have affected a jury it is difficult to say. There was little in it to suggest disease of the mind, and there was nothing in the case to suggest delusion.

In his recently published recollections Mr. Justice Travers Humphreys seems to deprecate taking away the decision in respect of a death sentence from the judges and giving it to the Home Secretary. Be that as it may, there will be considerable relief in many minds that Heath's strange case has forthwith been made the subject of a medical inquiry instead of merely leading to the repetition of the McNaghten rules in the Court of Criminal Appeal.

A GROUP of patients with disseminated sclerosis have initiated in New York the Association for Advancement of Research on Multiple Sclerosis, of which the chairman is Dr. Tracy Jackson Putnam, New York. The aims are to coördinate research, gather statistics, act as a clearing-house for information, educate the public on the problem of the disease, and collect funds for research. A large medical advisory board has been appointed.

In England Now

A Running Commentary by Peripatetic Co

THE latest experiments with yellow maize (*Lancet*, Oct. 5, p. 491) are a reminder that this winter marks the centenary of perhaps the experiment ever made with maize in human In 1846 the potato crop, the staple food of the poor, completely failed, and both the Government charitable organisations supplied vast quantities "Indian corn" or maize for cooking at home and up thousands of "kitchens," where the meal was before distribution at a nominal price, both to avo stigma of charity and to maintain the morale of the who were put to all sorts of road-making and hill- to earn money to buy the maize. For several afterwards hundreds of derelict wheelbarrows lay the roads and fields. Anthony Trollope, who has " back" so remarkably in the past few years, was the post-office surveyor, his job taking him over a part of the Irish countryside. He has left vivid tions of the ravages caused, especially among children, in his novel *Castle Richmond*. One wretche woman is made to say: "Is it the mail? An' shure a haven't I had it the last month past? Nothin' el Not a taste of a praty or a dhrop of milk for nigh a mont And now look at the childher. . . . They are dying the roadside." And she shows a child, aged nearly years, whose little legs seem to have withered awa its cheeks wan, yellow, and sunken; its head, and legs covered with sores. "Look at that," the mo says, almost with scorn, "that's what the mail has —my black curses be upon it, and the day that it came nigh the counthry."

* * *

The Royal Life Saving Society's handbook[1] make it all look so easy. Even the drowned man in bathing drawers wears a calm smile as the rescuer, someti disquietingly called the operator, pushes him in the shoves a knee in his chest, tows him ashore, leans on ribs, rubs his arms, rolls him over, and generally d him good. The rules for saving life were not always cut and dried; the drowned man is probably smili at the thought of what he escaped by being born after the society got down to its enlightened work. Dr Rowland Jackson, who published in 1746 *A Physi Dissertation on Drowning* (Price One Shilling), had such mine of information to draw on, and though his very first page he exclaims against "that ignor and unmanly Turn of Mind, commonly known by the Name of *Credulity*," he seems to have been led into accepting some pretty tall stories. There was the "Gardner of Froningholm," for example, who through the ice and "went perpendicularly to the Bottom, in which his feet stuck for sixteen Hours befo he was found." This sturdy fellow (for he survive said afterwards that he "perceived a Kind of Bladd before his Mouth which hindered the Ingress of the Water by that Passage, tho' it enter'd freely into Ears, and produc'd a Dulness of Hearing for Som Time after." Then there was the woman who had the misfortune to be thrice drowned. The first time she three whole days under water, "but the two other Ti had more Speedy Relief afforded her." She died at And so on, from the Painter of Falung, who was days in the water and had a good deal to say about to Laurence Jones, who continued seven weeks und water—though about him even Dr. Jackson seems to have felt a few qualms in his organ of faith.

From drowned men he passes to the drowned Pol swallows, who, on the word of Fortunus Licetus, toward the end of September "plunge themselves into Ditch and Rivers, where they remain conceal'd till about the Middle of May"; and clusters of these swallows tak out from below the ice only needed warming to come life again. Moreover, if released "they forthwith back to the Water and plunge themselves into it."

But Dr. Jackson's readiness to believe all he hea sprang from a human and practical desire to see th

ed resuscitated, and though nearly as credulous remedies as he is about recoveries, yet he gives lace to sensible measures. His opening directions carry the patient into a house and warm him ally before a gentle fire, wrapping him in warm and rubbing him until circulation is restored. He not believe in rolling patients on barrels because of his authorities had known it to cause sudden . He shares contemporary opinion on the value eeding but advises the utmost caution in the use rdials in the early stages. If other measures prove ectual he advises tracheotomy, and neatly describes method. If no tracheotomy tube is at hand the k of a common pipe—presumably a churchwarden— be slipped into the tracheotomy opening, and the ator (as the R.L.S.S. handbook would call him) ows into the Bole." He recommends another and h more extraordinary use for the common pipe, time loaded and burning. The small end is to be oduced into the anus, the bowl covered with a piece erforated paper, and the operator is then to blow cco smoke into the intestines as strongly as he ibly can. On one occasion, when this remedy was to trial at the instigation of a soldier, "at the fifth t, a considerable rumbling in the Woman's Abdomen heard, upon which she discharg'd some Water from Mouth and in a Moment after return'd to Life." Jackson was so much impressed with reports of this hod that he invented an instrument, illustrated in frontispiece, "contriv'd on purpose for impelling Smoke of Tobacco into the Intestines." It enables blower to operate from a distance of some , but has no advantage for the patient unless, the users of cigarette-holders, he prefers his smoke . One look at it is enough to prove that we ould all be very grateful to the Royal Life Saving ciety.

When my fellow peripatetic of Sept. 21 spoke of "swanning" he stirred up many memories of days in the Western Desert with the 8th Army, including one which throws light on the origin of the term. In the second desert campaign of November, 1941, a variety of codes were used for R.T. communication by the different branches of the Service. One of these, known as the "Bird" code, and originating, I believe, with the then D.D.M.S., 30 Corps, for use by medical units taking part in the campaign, referred to motor ambulances as "swans." One of the commoner sights in that campaign being ambulances crossing and recrossing the desert, "swanning" came to be applied to their activities. The term persisted, eventually becoming common 8th Army slang for any apparently aimless wanderings. From the 8th Army it diffused outwards to the rest of the Army, carried no doubt by old members of the 8th.

* * *

How tantalising it is to travel in the train past fields full of mushrooms, knowing that all we shall get this season is a quarter of a pound of tasteless cultivated things costing several shillings. We are still very conservative in this country about eating fungi other than the common mushroom, mainly because of the fear of poisonous toadstools, though Mr. Ramsbottom says in the *Times* that the toadstool is becoming more fashionable. His excellent King Penguin book on poisonous fungi shows how uncommon dangerous forms are, for he has to fill up his slim volume with kinds which are liable to give slight indigestion. Personally I don't think that we miss a great deal by our conservatism. To my palate few compare in flavour with a freshly gathered field mushroom, and in England it is an awful job to pick enough of other sorts to produce a decent portion. Even in France I have been faced with a repellant dish resembling tenderised 'Sorbo' rubber in the guise of a great delicacy.

Parliament

THE BILL IN THE LORDS

ACCOMMODATION in the smaller but by no means amped quarters now used by the House of Lords—hose proper benches are still occupied by the Commons was taxed to capacity when last Tuesday afternoon e LORD CHANCELLOR rose from the Woolsack to pen for the Government the Lords' debate on the econd reading of the National Health Bill. There was othing in Lord Jowitt's speech to suggest that during he parliamentary recess the Government has considered any revision of the Bill. Most of his survey and is arguments followed the now familiar lines of ministerial speeches in the lower House. The one new fact e disclosed was that the Government (adopting a suggestion of which Lord Moran had given notice) propose to et up a "Spens Committee" to consider and report pon the proper remuneration of consultants. He efended at length and with conviction the powers iven to the Minister under the Bill—powers without which, he said, it would be impossible for the Minister, s commander-in-chief of the health forces, to provide he service the country has been promised.

It was to these same powers, vested in one individual, hat the Earl of MUNSTER, opening for the Opposition, ok strong exception. He welcomed the conception f a National Health Service but was very sure that a etter and more democratic service could have been ramed if greater use had been made of local authorities. He hinted that his party would be putting down amendments in the committee stage designed to liberalise the dministration and preserve the autonomy of the oluntary hospitals.

The Marquess of READING saw in the Bill the logical levelopment of the social services inaugurated by the Asquith "Government of all the Talents," but feared the possibility of over-centralisation of administration in a Ministry of Health already overburdened with housing responsibilities. He believed that, with adequate devolution of power and function to the regional boards and to the executive councils, a service may be built not unsatisfactory to the doctors. He suggested that when the time comes it may be only the very few—and they the very elderly—who will prefer to "reign in Hell rather than serve with Bevan."

The Archbishop of YORK saw in the Bill a great opportunity for ensuring that preventable illness does not go unprevented. He was followed by the first of the medical speakers, Lord MORAN, who dealt with the need for establishing conditions of practice, in all branches of the profession, that will ensure the continued recruitment of the right men and women in numbers sufficient to provide a complete and balanced service. At present (but this may be partly due to demobilisation) the would-be entrants to the medical schools are more than the schools can absorb. If medicine is to remain attractive, conscious effort is needed to make all branches of medical work satisfying. In particular, the provision of an extended consultant service should not be allowed to exclude the general practitioner from his proper access to, and share in, the work of the hospitals. Lord Moran referred to the present difficulty in which the Minister finds himself in his negotiation with the Insurance Acts Committee. He felt this was largely a procedural difficulty which with good will could still be overcome. He appealed to the Minister to try again to come to some agreement with the profession before prejudice over this present trouble mars the reception of the final scheme.

Lord TEVIOT, speaking from knowledge gained from his long chairmanship of the Teviot Committee, stressed the even greater need for attracting urgently and by all possible means many more students to dentistry. The country, he said, could well afford to have each year three times the number who now qualify.

Lord INMAN saw in the new service not the death of the voluntary hospitals but enlarged opportunity free from all-pervading worries about finance. Lord HORDER regretted the lack of real consultation with the medical profession in the preparation of the Bill, and was glad that the Minister at last realised that there can be no new service without the willing coöperation of the men and women who have to work it.

The first day's debate ended with a plea from Lord AMULREE for a better, a more scientific, and a more humane treatment of the problem of the chronic sick.

The debate continued on Wednesday, when Lord LISTOWEL replied for the Government to the first day's critics.

Letters to the Editor

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—Some twelve months ago I had the opportunity of visiting Professor Winkelbaum's clinic in Graz. In his wards I noticed several patients with what he called perforated duodenal ulcer. They had not been operated upon. "Why?" I asked. The professor was obviously a little taken aback by so naive a question. The substance of his reply was that if the cases were brought into hospital early for treatment the ulcer sealed itself off. It was necessary to operate only on cases, usually late, in which there was evidence of a lot of fluid in the peritoneal cavity; and these were usually gastric, not duodenal ulcers. The routine was to await recovery from perforation, and in 3–4 weeks perform a partial gastrectomy.

Whether the latter action is commendable is a subject for debate. But the efficacy of the conservative treatment of perforation in these cases left no room for doubt, and made me realise that there was a great need for revision of the usual and long-established teaching of immediate operation for all cases of perforation: for the mortality of such a procedure is considerable, and the postoperative morbidity great.

Mr. Hermon Taylor's article of Sept. 28 is both timely and encouraging. The results—admittedly this is a small series—compare favourably with any that could have been obtained by routine laparotomy. It will be noted that nearly all the ulcers in Mr. Taylor's series were duodenal. Conditions for spontaneous sealing of a perforated duodenal ulcer are more favourable than those for sealing of a perforation on the anterior wall of the stomach; and I feel that if one is to adopt conservative treatment it may be wise to restrict it to duodenal ulcers, if differential diagnosis permits the distinction to be made.

London, W.1.

HAROLD C. EDWARDS.

SIR,—Although I have never had the courage to treat without operation cases of frank perforation of a peptic ulcer as practised by Mr. Hermon Taylor, I have frequently treated by generally conservative means those cases in which the diagnosis appeared somewhat indefinite and which appeared clinically to be cases of what we might call a local peritonitis in relation to an ulcer—such cases as are often referred to as "leaking ulcers." And in such cases the symptoms have subsided, though there has been noted from time to time a gas shadow under the diaphragm a few days later when a barium meal was about to be contemplated. This has led me to the conclusion that in many so-called perforated ulcers there has been a gas leak only, which can settle down with restriction of fluids by mouth for 24 hours and a dose of morphine without actually going to the trouble of gastric aspiration in this less severe type of case.

One other point I should like to mention, though it is not exactly relevant: it has been my experience that operation on late cases of perforation (i.e., those over 24 hours old) is almost inevitably fatal, but that a number of these cases may be saved by intravenous fluids coupled with a small suprapubic drain inserted under local anæsthesia. This form of drainage is recommended because I have always felt that a quantity of fluid plus gas inside the cœlom has kept the viscera of the upper abdomen apart and so prevented the falling together of those tissues, the apposition which might result in the perforation becoming sealed off.

Selly Oak Hospital, Birmingham.

JAMES GORE.

SIR,—I read Mr. Taylor's paper with great interest. Thirty years ago I reported a case in which perforation of an ulcer of the lesser curvature was cured by non-operative treatment.[1] The ulcer, having perforated between the layers of the lesser omentum, was observed by radiography; the perforation disappeared, and later the ulcer greatly diminished after routine dietetic treatment. So far as I am aware this was the first case in which gastric perforation was deliberately treated medically without operation, as noted previously by me.[2] The X-ray pictures of the ulcer before, during
after the perforation have been published in my
book.[3] Many years later Prof. M. Roch,[4] of
reported a case of "spontaneously healed
perforation."

Conservative treatment should be restricted to
perforations which are sealed off. Therefore the q
arises of how these cases are to be recognised
partial or total absence of muscular rigidity
be regarded as pathognomonic of a sealed perf
since rupture of an ulcer sited on the posterio
of the duodenum or of the stomach induces pri
rigidity in the musculature of the *posterior* abdo
wall. Only later, mostly after 2 or 3 days, with
appearance of meteorism, and intestinal obstructio
it possible to make a certain diagnosis of diffuse p
tonitis, indicating that the perforation was not sealed
An operation at that stage, however, carries a great ri

Hitherto it has not been known, or even suppo
that in most cases the perforation was sealed off. T
value of Mr. Taylor's treatment will be enhanced if
early and reliable sign differentiating between op
and sealed perforations can be found.

EUGENE ROSENTHA

CHILDREN IN DAY NURSERIES

SIR,—Dr. Menzies, in her paper of Oct. 5, quotes m
as having described the Oxford survey of the inciden
of infections in day nurseries as being "at the sa
time too scientific and not scientific enough." Th
suggests a serious misunderstanding of my comme
which were, actually, that the Oxford survey was
much of an academic exercise and was based on d
whose scientific validity was open to serious doubt

I use the term "academic exercise" to describe
type of investigation which draws inferences fr
observed facts but does not concern itself with th
practical importance or application of those inferen
and it is with regret that I notice that other investigat
into the welfare of nursery children seem to share th
character.

The recent paper on the incidence of infections of th
respiratory tract, published by a group of members
the Medical Women's Federation, though unimpeachab
so far as data and analysis were concerned, is a case
point. Its findings were, in brief, that a child who lea
home to enter a nursery runs thereby a serious risk
catching colds or bronchitis. But it has been a matte
of common knowledge for years that the child's fir
departure from the restricted circle of the home to ent
a mixed group is likely to be followed by a series of col
and coughs. The two pertinent questions, "What is th
long-term effect on the child's health of these colds?"
and, "How much harm is done by shifting this pha
of infection from the normal school entrance age
4–5 years to the earlier age of 1½–2 years," remai
unanswered.

Dr. Menzies is concerned because in her nurseries
the gain in weight of the entrants is "unsatisfactory."
Her anxiety would be pardonable if the children were
being fattened for the pot, but it is rash to suggest th
at this particular stage in a young child's life it is possi
to lay down arbitrary standards of satisfactory gain
purely physiological grounds. It is quite true that l
of weight may arise from emotional disturbance.
may also arise from a change of diet, from a change fr
a bad diet to a good one, or from the fact that the chi
for the first time taking adequate exercise and discover
the open air, is merely getting rid of his "puppy fat."
It is difficult, if not impossible, to assess whether eit
the emotional disturbance or the failure to gain wei
is, in any given child, likely to cause long-term har
and Dr. Menzies is not to be blamed for not havi
attempted it. Yet without such an assessment h
investigation is barren.

Can we be realistic about this nursery business?
majority—often a large majority—of nursery childre
are the children of mothers who are compelled to wo
either by poverty or by the needs of industrial reco
struction. It is fallacious to compare nursery childr

ildren from normal homes; the true comparison children from necessitous homes and children e cared for by "daily minders." I should be to see a state of things in which no woman with l under the age of two years was compelled by or economic circumstances to go out to work, Dr. Menzies finds me "biased in favour of nursery ion" it is a bias in favour of the nursery as against isfactory alternatives. I plead guilty, also, to a gainst unpractical "research" and would suggest questions with which future ambitious researchers profitably occupy themselves.

What is the relationship of infection in nursery days to s or physical defect in later childhood?

Does the school record of ex-nursery children suggest their "social training" in the nursery has helped them rd social adjustment?

Does the comparison of infection-rates in different ries, and possibly in different towns, suggest that certain diable factors are associated with high infection-rates?

ut there is, as yet, no totalitarian suggestion that all dren, from rich families and poor, shall be comorily drafted into nurseries at the age of six months, therefore no need to discuss whether nurseries are re not an evil in themselves. In point of fact, nurseries our present therapy for an admitted social evil, and concern should be to investigate their work conctively with the intention of improving them.

ARSENICAL CHICKENPOX

SIR,—Dr. Parkes Weber (Sept. 14) may be interested an account of arsenical polyneuritis in a family, of whom developed both local (segmental) and eralised zoster 12 and 19 days respectively after estion of arsenic (*London Hosp. Gaz.* July, 1946, 144, and Clinical Supplement, September, 1946. xiv).

This case supports the theory of activation by arsenic a latent virus infection, since the zoster rash appeared days after a single dose of arsenic. This is the usual ubation period of the naturally occurring disease, that if the cause were exogenous exposure must have en place at the same time as the poisoning—which mprobable. The postulated selective action of arsenic the pyruvate enzyme system of cells, interfering h their normal oxidation, may possibly explain assumption of activity of a cell parasite such as a us.

oughton, Essex. **A. L. CRADDOCK.**

WOMEN IN MEDICINE

SIR,—In reply to Dr. Usborne's letter of Sept. 28, should be stated that, apart from direction of the ecently qualified, it was not found necessary to direct edical women, except perhaps in a few isolated cases, ince those available by age for direction were either lready employed or were not liable. It would seem, herefore, that those medical women who resumed work fter definite intervals of retirement did so in spontaneous esponse to the urgency of the times and the increased opportunities for work, especially in part-time posts uitable for those with family ties.

ANNIS GILLIE
mley, Kent. Hon. Secretary, Medical Women's Federation.

USE OF REASSURANCE

SIR,—For some time I have been experimenting with a method of explanation and reassurance designed for long-standing and severe psychoneurosis.

It consists in a short elementary and ad-hoc quasi-correspondence course on the effect of emotion on bodily and mental functioning. On each visit the patient is given a lesson stencilled on a sheet of paper with a large blank space. He takes this home, studies it, and writes on the blank space examples, illustrating the point of the lesson from his own experience and what he knows is the common experience of others. On his next visit these examples are discussed and he is given the next heet, which is dealt with in the same manner, and so on to the end of the course.

Thus the patient teaches himself, with only the minimum of guidance, to understand his illness, or rather, to arrange, in relation to his own symptoms, knowledge which he and everybody possesses about the effects and manifestations of emotion. The reassurance that the patient feels is all the stronger because the explanation has been arrived at by himself.

I hope to publish a full account of this method in the near future.

Graylingwell Hospital, Chichester. **M. B. BRODY.**

ROYAL MEDICAL BENEVOLENT FUND

SIR,—Christmas once again draws near and it is time to ask the hospitality of your columns to launch our annual Christmas appeal on behalf of the poor beneficiaries of this Fund.

The reasons for this appeal are now well known to all your readers and there is no reason to stress them again. I would rather emphasise the point that they are as cogent as ever. It is true that the old-age pension which is now in force, whilst making the financial position of old people more bearable—whereas previously it was quite intolerable—still means that the actual increase in annual income is only £41 12*s*., which, bearing in mind the tremendous increase in the cost of living, still makes the position of the poor housewife very difficult indeed. Further, very many of our beneficiaries are under 70 years of age and so not able to draw this pension. Lastly, there is that very real sense of being "not forgotten" at the festive time of Christmas, and the knowledge that our Christmas gift will ensure the purchase of a few extra luxuries which just make all the difference.

I recall that my appeal last year for £2000 to enable the Fund to give £4 to every beneficiary—a record sum for which I scarcely dared to hope—actually reached the grand total of £2127, and I know every generous donor will feel amply repaid by the gratitude and pleasure these gifts have evoked. May I venture to plead for a similar sum this year? I feel sure that, although I well recognise that times are very difficult for everybody just now, the still greater difficulties and anxieties of our very poor brethren will not pass unheeded.

Please forward contributions marked "Christmas Gifts" to the secretary, Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15, who will gratefully acknowledge.

ARNOLD LAWSON
London. President, R.M.B.F.

MEGALOBLASTIC ANÆMIA IN CHILDREN

SIR,—In your annotation of Sept. 28 you say that "ordinary crude [liver] extracts should be used and not the purified extracts specially designed for the treatment of pernicious anæmia, like 'Anahæmin.'" If it is implied that crude liver extracts administered *parenterally* provide a reliable method of treatment in cases of megaloblastic anæmia in children, I wish to dissociate myself from this view. From my own experience, and from my reading of the literature, it seems that oral liver therapy is by far the most effective and certain therapeutic measure hitherto available, not only in megaloblastic anæmia of childhood but in other types of megaloblastic anæmia proving refractory to refined parenteral liver extracts—with the possible exception of tropical nutritional anæmia, in which autolysed yeast may be preferred on the score of cheapness.

Your annotation quotes the case of a boy of 14 years, previously reported by me, in which "a purified liver extract was ineffective, but proteolysed-liver by mouth and a crude liver extract parenterally produced a remission. . . ." In my original report, however, it was pointed out that the crude parenteral extract 'Plexan' was ineffective, the condition relapsing with this treatment but responding when it was replaced by proteolysed liver given by mouth.

I am aware that claims have been made, from time to time, for the superiority of 'Campolon' to more refined parenteral liver extracts in the treatment of certain types of megaloblastic anæmia. Opinion on this question, however, is by no means unanimous. Nevertheless, if it be accepted that genuine crude liver extracts prepared by the Gänsslen or some similar process may in certain cases be more effective than purified extracts, I feel that your advocacy of "ordinary crude extracts" may be dangerous and misleading, since the various preparations on the market vary considerably in their constitution and mode of preparation. Some of them appear to differ from refined extracts mainly by their greater content of water.

Regarding the type of oral liver therapy effective in megaloblastic anæmias, including those of childhood, refractory to injections of refined extracts, my own experience has demonstrated the efficacy of proteolysed liver ('Hepamino') in daily doses of $1^1/_2$ oz., but a few recent trials suggest that oral liquid liver extract, now generally available once more, may prove equally efficacious.

Muirhead Department of Medicine, University of Glasgow. L. J. DAVIS.

EXTRANEOUS CAUSES OF UTERINE BLEEDING

SIR,—Nobody will quarrel with your advice to the gynæcologist, confronted with a case of menorrhagia, to bear in mind the various systemic conditions which may cause this symptom (Sept. 28, p. 460). But if you include idiopathic hypochromic anæmia among the extraneous causes of uterine bleeding, are you not putting the cart before the horse?

Bethnal Green Hospital, London, E.2. HERBERT LEVY.

THE NATIONAL LOAF

SIR,—The fact that an attempt has been made to keep secret the instruction to force us to swallow extra doses of calcium, as revealed by Sir Ernest Graham-Little's letter of August 17, is in keeping with other strange methods employed in this business.

Originally the scheme applied to white bread, which does not contain phytic acid, and not to brown; the idea underlying the proposal was to prevent osteoporosis among the adult population. The authority concerned was challenged to produce a dozen cases of calcium deficiency in adults (*Lancet*, 1941, ii, 25) but did not do so. The proposal to adulterate white bread had to be dropped. But evidently the authority in question felt that its amour-propre had suffered by the failure of the Food Minister to act on its suggestion. In such circumstances the phytic acid bogy was resurrected, and now it was maintained that only brown bread needed fortifying and not white. But the American "Council on Foods" in 1937 came to the conclusion that "there is no good evidence for the existence of a decalcifying factor in cereals" (quotation from *J. Physiol.* 1942, **101**, 304). Long after the recommendation to add calcium was made it was sought to justify this recommendation. The first paper by McCance and co-worker was received by the *Journal of Physiology* in October, 1941 (*J. Physiol.* 1942, **101**, 44). But in a paper received in April, 1942, by that journal these workers had to admit that their first paper was inconclusive, because "brown bread had a laxative action," and the negative calcium balance therefore might have been due to this factor. Still no justification! A new investigation therefore became necessary. No-one would hang a dog on the type of evidence offered in the second paper. Thus it was virtually admitted that at the time the recommendation was made to add calcium to bread there was no valid reason for the proposal. Otherwise there would not have been a call for the two papers. It should be borne in mind that the recommendation was made years before the appearance of these two papers. A more damning admission it is difficult to imagine. Years after the recommendation, and after an investigation, the workers had to admit that the evidence to justify the proposal was inconclusive. To force forty million human beings to consume extra doses of so potent a substance as calcium without valid reason is surely an amazing procedure! Furthermore, Mellanby himself admitted that much of the phytic acid is destroyed in the process of baking (*Nature, Lond.* 1944, **154**, 394); and people usually eat baked bread.

Again, when bread became whiter the Minister of Food stated in Parliament, in reply to a question by Sir Ernest Graham-Little: "The addition of calcium to the loaf was retained when the extraction-rate was reduced to 80% in order to ensure good intakes of calcium as a beneficial nutritional measure" (House of Commons, Feb. 20, 1946). When the bread was dark it was phytic acid that required calcium; when it became whiter it was calcium deficiency in dietary calcium; and now it is again phytic acid.

If the authority who recommended the adul our bread has a good case, why this twisting and and concealing? The subject is of grave and, in the interest of public health, an indepe inquiry into the whole matter by a competent long overdue.

Liverpool. I. H

CHILDREN WHO SPEND TOO LONG IN

SIR,—The view that some children who are on th all day need longer sleep is, I think, a relic of the before metabolism became an accurate science. If true, why is it that as the child gets older and his ca expenditure goes up he needs less and less sleep? view may arise from the confusion of length of with *intensity or depth of sleep and with ability to* asleep easily. Activity certainly leads to easy s During the examination of parents I find repeat that these three factors are tied up in confusion from meaning the same thing, length and intensit sleep are vaguely in inverse proportion to one anothe

Whatever may be practicable in the home, it is m more satisfactory to arrange the children's hours in according to age-weight grouping than *according* "activity." Mothers require guidance *in this* ma particularly during the first three years of a child's for it is then that the effects of the long tran period from animal polyphasic sleep to human m phasic sleep are most intense and most badly handle

Westcliff-on-Sea. JOHN A. MCCLUSK

Obituary

WALTER LANGDON-BROWN

KT., M.D. CAMB., SC.D., LL.D., F.R.C.P.

IT is perhaps as a teacher in the profession Sir Walter Langdon-Brown will be best rememb When he died on Oct. 3 he was 76 years of age was still capable of influencing and inspiring men, because maturity never impaired the of his mind. Holding high professional position physician at St. Bartholomew's and regius profes Cambridge, he could yet be intellectually unconventi and he showed courage as well as skill in advoc unfamiliar ideas.

Press Portrait

His father was the Rev. John Brown, Con minister at Bedford, who wrote what has become standard life of John Bunyan. Born at Bedfor August 13, 1870, he was named after his mother's uncle, J. Langdon Down, physician to the London Hospital. Thus heredity contrived to blend in him those diverse qualities that make for distinction in medicine and literary accomplishment. On leaving Bedford School he was too young to go to Cambridge, where he had won a scholarship at St. John's College, and he spent a useful year at Owens College, Manchester, working at biology under Milnes Marshall. At Cambridge he took a first in both parts of the natural sciences tripos and won a Hutchinson research scholarship at his own college. The thorough training in physiological principles and thought which he gained was the background of his medical career, enabled him to consider his clinical problems wi scientific approach and to teach with an except clarity.

Entering Bart's with the senior science schola in 1895, he qualified in 1897, and in the same year be house-physician to Samuel Gee, one of the best cl teachers of his time. In 1899 his bent towards physi m to become junior demonstrator in physiology, two years he was senior demonstrator. At the same he continued his clinical work and teaching in the of casualty physician and demonstrator of practical cine. In 1906 he relinquished his appointment in hysiological department to become medical registrar lemonstrator of morbid anatomy; but it was not until at the age of 43, that he was elected to the senior as assistant physician. He became a full physician)24, and retired from Bart's in 1930, but continued some time to work at the Metropolitan Hospital to h he had been appointed at the beginning of the ury.

angdon-Brown was widely read on many subjects. his ward rounds were enlivened and illustrated references to English literature. From early in his eer he was especially interested in endocrinology and wed his originality of thought, and he was one of first to draw attention to the similarity of the tures produced by lesions of the anterior pituitary 1 of the adrenal cortex, some years before Cushing scribed the syndrome associated with pituitary sophilism. The importance which he placed on a owledge of physiology in the practice of medicine is ected in his Croonian lecture, delivered at the Royal llege of Physicians in 1918, on the Rôle of the mpathetic Nervous System in Disease, and in his st-known book, *Physiological Principles in Treatment*, st published in 1908, and now in its eighth edition. him, more than to any other man in recent years, longs the credit for teaching medicine as applied ysiology, and he introduced successive generations of dical students and doctors to the new facts and ideas which physiology was so prolific between the two rs. If he sometimes, perhaps, over-simplified the ysiology, this was the result of those qualities which de him such an excellent expositor. His attention things of the mind led him naturally to consider minds of his patients, and the close linkage between endocrine glands, the autonomic nervous system, and emotional life brought him face to face with this ect of the body-mind relationship. He was thus ioneer of what is now called psychosomatic medicine, ugh he was not much interested in the more recondite ools of medical psychology and preferred the simpler proach of Adler.

From the first Langdon-Brown showed himself a fertile iter with an unusual range. He was joint editor of *e Practitioner's Encyclopædia of Medical Treatment*, blished in 1915; and his own works included *The mpathetic Nervous System in Disease* (1920), and *The docrines in General Medicine* (1927). All these had a actical application to the art of clinical medicine, of ich he was a master. His wide learning, his breadth vision, and his erudite style are seen at their best in *us we are Men* (1938), which examines human nature, d in *Some Chapters in Cambridge Medical History*, a all gem at which he laboured with increasing difficulty ring the last year of his life. He had a sense of history ich constantly illuminated the present with the past. me of his lectures and occasional writings, such as *he Pursuit of Shadows*, deserve to survive as models their kind, for he brought wit and elegance as well culture to the discussion of clinical problems.

At Cambridge, because of age-limit rules, he occupied e regius chair for only three short years, from 1932 1935, but he faithfully maintained its great traditions. loved Cambridge, with which he was intimately sociated by many ties of relationship. "In his own ofession," writes L. W., "there can have been no an better known or better loved by young and old ike. It was revealing to be his co-examiner and to note now many candidates he would put at their ease at the beginning of a viva by inquiring whether they were he sons of his medical or lay friends. His wisdom, his experience, and his counsel were always available to the undergraduate, the newly qualified, or the embryo professor, and many sought his advice, always kindly nd patiently given however trivial the problem." All Bart's men," A. W. S. writes, "will call to mind -B.'s arrival in the square for his ward round at ten minutes to two, with cigar, not yet fully smoked, that nd to be discarded. On his rounds the opinion and argument of anyone, however lowly, were always carefully considered, and his kindly manner endeared him to his housemen and students. He would never hesitate to seek the opinion of a junior on a matter about which there was some doubt: humility is one of the marks of a great man, and this L.-B. had. Of him can be said what Sir Norman Moore has said of his old chief, Samuel Gee, 'He was a constant friend and a pleasant companion, a learned physician, and a most excellent teacher'."

At the Metropolitan Hospital, as well as Bart's, he was a tower of strength. A colleague there, P. H., speaks of "his constant endeavour to relate clinical observation to physiological knowledge and to bridge the gap between the laboratory and the ward," and recalls that he was one of the first in this country to apply the work of Pavlov on gastric secretion and the teachings of Lenharz to the treatment of patients suffering from gastric and duodenal ulcer. "He inspired his house-physicians with a scientific attitude while at the same time taking a broad view of the problems of the individual patient."

The same theme is again repeated by another and younger associate, R. G. "Langdon-Brown," he says, "was one of the first, perhaps the first, of modern physicians to attempt to apply to clinical medicine the teachings of modern physiology—the physiology, that is, of the present day rather than of his student days. He acted as a catalyst between the laboratory and the ward, and this line of thought inevitably led him to endocrinology as a major interest, endocrinology not as a specialty (for his was too Hippocratic a view for the admission of a specialty) but as a tool to the better understanding of medicine as an indivisible whole. For this reason he gave his support to the formation of a section of endocrinology of the Royal Society of Medicine, and, knowing his end was near, was happy to see it in being in time to become its first president. He was too ill to read his inaugural lecture, but not too ill to write it. His mind was unclouded to the end and only a few days before his death he was able to remember full details of a case not seen for years." In this last presidential address he described the development of endocrinology, adding "I ventured to call the pituitary gland 'the leader of the endocrine orchestra,' though it later transpired that the hypothalamus holds the still more important rank of conductor." This now celebrated simile is an indication of his aptitude for exposition.

His wisdom was broadly based in experience. As a young man he served in the South African War as senior physician at the Imperial Yeomanry Hospital at Pretoria, contributing later to the book on *Imperial Yeomanry Hospitals in South Africa*, and he kept up his military associations as a Territorial. As a young man, too, he lectured to working men's institutes on biology and physiology. Afterwards an examiner in many universities, he went to Egypt in 1936 on behalf of the General Medical Council to report on teaching and examinations as there conducted, and he presided over the Committee on Postgraduate Training in Psychological Medicine which reported in 1943. Through his multifarious activities he came to know an immense number of people, and he was a charming host with a great knowledge of good food and good wine, a vast fund of anecdote, and a gift for stimulating conversation. "One remembers him sitting in his combined consulting-room and study in Cavendish Square, surrounded by cats, or standing like a rock in a seethe of more mobile persons at some medical meeting. He said many good things, which he enjoyed as much as his hearers. He was a humanist in every sense of the word: 'in mind, as in body, he was *totus, teres, atque rotundus*'."

Langdon-Brown's distinction and industry brought him many honours. Elected a fellow of the Royal College of Physicians in 1908, he became senior censor and delivered the Harveian oration of the college in 1936. He was a fellow of Corpus Christi College, Cambridge, and received honorary doctorates in science from Oxford, and in law from the National University of Ireland, and from Dalhousie University, Canada. The Royal College of Physicians of Ireland elected him an honorary fellow in 1940, and he was also an honorary fellow of the Royal Society of Medicine, the Faculty of Radiologists, the Hunterian Society, and the Harveian Society, and

Notes and News

ON THE RECORD

March Westminster Hospital broke new ground by ding a department of medical photography under the ie charge of a doctor. This week the department has a exhibition. Part of its work is to help in clinical gation by enabling the staff to keep permanent visual s and to compare serial studies. But it also caters for the student; already one film (on inflammation) een made, and others are planned. For tutorials, graphic displays—on gout, for example—are arranged; onsiderable use is made of filmstrip, which is shown, g other purposes, as replacing the familiar lantern-slide. a projector that can be fitted easily into a suitcase, res are reproduced on a screen up to any magnification the light will allow. A lecturer can carry 300 pictures ft. of 35 mm. film, weighing no more than an ounce; and hose that choose to vary the order of their showing, the can be divided and the pieces mounted as for a lantern-, but without the lantern-slide's cost, weight, and fragility. ie exhibition shows clearly enough that photography has 1 to offer both student and doctor; it may, perhaps, ipt others to follow the Westminster Hospital's lead.

A NEW JOURNAL OF ANÆSTHESIA

E Association of Anæsthetists is launching a new quarterly ial, *Anæsthesia*, of which the first number has appeared month. Edited by Dr. C. Langton Hewer, assisted by R. Blair Gould, the journal will be primarily scientific, t will also publish official news of the association. "It become obvious," writes the editor, "that the rapid rance in all types of anæsthetic and analgesic technique uires fuller and quicker expression than can be provided the overloaded columns of the general medical press." Alfred Webb-Johnson, P.R.C.S., in a foreword, remarks the fitness of this, the centenary of the first operation under ieral anæsthesia in this country, as the year for initiating venture. Among other papers are an account of the ociation since its inception, by Dr. H. W. Featherstone, first president, and a sketch of anæsthetic practice a ndred years ago by Dr. A. D. Marston, who is now president.

NARCOTICS CONTROL

THE Drug Supervisory Body and the Permanent Central ium Board, which were established under the auspices of e League of Nations for the international control of narcotics, e meeting in London this week and next. The Economic d Social Council of the United Nations has lately agreed that e present members of these two bodies should be invited to ntinue for the time being in office. The British repre-ntative is Sir Malcolm Delevingne, who is chairman of the rug Supervisory Body.

Iniversity of London

Mr. Frank Dickens, D.SC., F.R.S., has been appointed to the hilip Hill chair of experimental biochemistry tenable at the Iiddlesex Hospital medical school.

In 1923 Dr. Dickens was appointed first assistant in the Courtauld nstitute of Biochemistry at the school. From 1933 until this year ie worked at the Cancer Research Laboratory at the Royal Victoria Infirmary, Newcastle-on-Tyne, and he was research director for the North of England council of the British Empire Cancer Campaign. In March of this year he returned to the Courtauld Institute of Biochemistry.

Dr. Clifford Wilson has been appointed to the university hair of medicine tenable at the London Hospital medical llege, as from Oct. 1.

Dr. Wilson, who is 40 years of age, qualified from the London Hospital in 1931 and took his D.M. Oxfd five years later. After demonstrating in physiology at the London he went with a Rockefeller research fellowship to work at Harvard medical school and Boston City Hospital under Dr. George Minot. He returned to this country in 1935 and was appointed assistant director of the medical unit of the London Hospital in 1938. From 1939 to 1942 he was E.M.S. physician in the London Hospital sector, and from 1942 to 1946 he was on military service, attached to no. 2 Medical Research Section, G.H.Q., Home Forces. Last year he became acting director of the medical unit, London Hospital. Dr. Wilson is the author of papers on renal lesions in hypertension, and was associated with Prof. Arthur Ellis in work on Bright's disease on which Professor Ellis's Croonian lectures were based.

Dr. J. L. D'Silva has been appointed, as from Oct. 1, to the university readership in physiology tenable at St. Bartholomew's Hospital medical college, where he has been lecturer in physiology since 1944.

Mr. J. F. Danielli, D.SC., has been appointed to the university readership in cell physiology tenable at the Royal Cancer Hospital, as from Oct. 1.

Royal College of Physicians

The Charles West lecture will be delivered on Tuesday, Nov. 19, at 5 P.M., by Prof. J. C. Spence, whose subject will be the Care of Children in Hospital.

Royal College of Surgeons of England

Three lectures are to be delivered at the college, Lincoln's Inn Fields, London, W.C.2, by Prof. Alexander Lipschutz (Chile), who will speak on the Tumorigenic Action of Steroids and its Implication for the Problem of Cancer (Oct. 28); the Antitumorigenic Action of Steroids (Oct. 29); and the Steroid Balance and the Antitumoral Autodefence (Nov. 1). The lectures, which will be given at 3.30 P.M. on each day, are open to medical practitioners and advanced students.

Royal College of Obstetricians and Gynæcologists

At a meeting of the council, held on Sept. 28, the following were admitted to the membership:

H. R. Arthur, S. J. Barr, B. E. Blair, Catherine I. Blyth, Joyce Burt, Harold Burton, G. B. W. Fisher (in absentia), R. L. Hartley, Derek Jefferiss, Iola L. T. Jones, L. W. Lauste, Margaret Orford, H. C. Perry, D. L. Poddar, Esther M. Pollock, J. E. Scott-Carmichael, E. W. L. Thompson, T. G. E. White.

At the end of the meeting Mr. William Gilliatt assumed the office of president, Sir William Fletcher Shaw and Mr. James Wyatt of vice-presidents, and Mr. A. A. Gemmell of treasurer.

Faculty of Radiologists

The following are the officers of the faculty for the present session: president, Dr. C. G. Teall (Birmingham); vice-presidents (radiodiagnosis), Dr. Peter Kerley (London), (radiotherapy), Dr. Robert McWhirter (Edinburgh); immediate past president, Dr. Ralston Paterson (Manchester); warden of the fellowship, Dr. S. Cochrane Shanks (London); treasurer, Mr. G. F. Stebbing (London); secretary, Dr. J. F. Bromley (Birmingham).

Research Defence Society

The annual general meeting will be held at 26, Portland Place, London, W.1, on Wednesday, Oct. 23, at 3.15 P.M. The Stephen Paget memorial lecture will be given by Prof. N. Hamilton Fairley, F.R.S., who will speak on War-time Research in Malaria and Other Tropical Diseases of Military Significance.

Tuberculosis Course at Newcastle

The Tuberculosis Educational Institute announces a refresher course, for medical practitioners and tuberculosis officers, at the Literary and Philosophical Library, Westgate Road, Newcastle-upon-Tyne, from Nov. 4 to 9. Programmes may be obtained from Dr. Harley Williams, Tavistock House North, Tavistock Square, London, W.C.1.

College of Pharmaceutical Society

Opening the college's 105th session in London on Oct. 2, Sir Percival Hartley, F.R.S., director of biological standards at the National Institute of Medical Research, recalled the valuable work undertaken by the health organisation of the League of Nations. The organisation had advanced the prospects of an international pharmacopœia—a project which had been under discussion for over half a century—and this year had published a report which could fairly be regarded as the nucleus of such a pharmacopœia. "My experience," he concluded, "has convinced me that international coöperation among men of science is not only easily secured but is a kind of natural impulse."

Hunterian Society

A dinner meeting will be held at Pimm's (3, Poultry, E.C.2) on Oct. 14, when Dr. J. B. Cook will deliver a presidential address on the Evolution of Municipal Medicine. On Nov. 18, at the Apothecaries' Hall, a discussion on the advertisement of proprietary medicines will be opened by Mr. Hugh Linstead, M.P. On Dec. 16, at a further dinner meeting, Dr. Geoffrey Evans will open a discussion on flatulence. The Hunterian lecture will be delivered at the Mansion House on Jan. 20, 1947, by Professor Debaiseux (Louvain), whose subject will be Hypotension in Intracranial Injuries. The annual dinner will be held at Grosvenor House on Feb. 13. On Feb. 24 Mr. Zachary Cope will deliver the Hunterian oration on Literature and Doctors, and on March 17 there will be a dinner meeting at which a discussion on Sprains and Strains is to be opened by Sir Reginald Watson-Jones.

Society of Apothecaries of London

Gillson Scholarship in Pathology.—This scholarship of £105 a year is open to candidates under 35 who are licentiates or freemen of the society or become so within 6 months. The regulations may be had from the registrar, Black Friars Lane, E.C.4.

Society for the Study of Addiction

On Tuesday, Oct. 15, at 4 P.M., at 11, Chandos Street, London, W.1, Dr. W. R. Bett will give an address entitled Poppies, Dawamesk, and the Green Goddess: an Exotic Study of Literary Genius.

Medical Society for the Study of Venereal Diseases

A general meeting will be held at 11, Chandos Street, London, W.1, at 2.30 P.M. on Saturday, Oct. 26, when Dr. F. R. Curtis will speak on Venereal Disease in Occupied Germany.

Food and Agriculture Organisation

Mr. S. M. Bruce, F.R.S., has been appointed chairman of the preparatory commission appointed at the F.A.O. conference in Copenhagen to examine methods for setting up a world food board (see *Lancet*, Sept. 28, p. 463). The first meeting of the commission will be held in Washington on Oct. 28. Mr. Bruce, who was prime minister of Australia from 1922 to 1929 and represented Australia in London from 1932 to 1946, took a leading part in the social and economic work of the League of Nations.

Centenary of Anæsthesia

Two further celebrations of the centenary of anæsthesia are announced to be held on Oct. 16, the anniversary of Morton's first operation at the Massachusetts General Hospital. At 2.30 P.M. there will be a special meeting of the history of medicine section of the Royal Society of Medicine at 1, Wimpole Street, London, W.1, when papers on the development of anæsthesia will be read by Prof. Charles Singer, Mrs. Barbara Duncum, Dr. Joseph Blomfield, and Dr. E. Ashworth Underwood.

After this meeting, at 4.45 P.M., Lord Moran will open an exhibition of anæsthetic apparatus and literature at the Wellcome Historical Medical Museum, 183, Euston Road, N.W.1. The exhibition will remain open until Dec. 31.

Middlesex Hospital Dinner

Presiding over the annual dinner held in London on Oct. 4, Dr. G. E. Beaumont spoke of losses from the honorary staff by retirement (Lakin, MacCormac, Cockayne, Gordon-Taylor, Webb-Johnson, Hastings, Greeves, Bankart) and by death (Voelcker, Berkeley, Bennett). He welcomed the appointment of F. Ray Bettley as dermatologist, O. P. Dinnick as anæsthetist, A. J. B. Goldsmith as assistant ophthalmic surgeon, R. S. Handley and C. J. B. Murray as assistant surgeons, P. H. Newman as assistant orthopædic surgeon, and Arthur Willcox as assistant physician. Mr. Plimsoll had been succeeded as secretary by Brig. Harvey Roberts. Meanwhile professors seemed to be sprouting on every bush, perhaps because of the wet summer; and the wisdom of the young suggested that original sin has been replaced by original knowledge. Dr. H. E. A. Boldero, as dean, spoke of changes in the medical school, including the retirement of Prof. S. Russ, the promotion of Dr. R. W. Scarff to be professor, and the return of Prof. F. Dickens, F.R.S., to the Courtauld Institute. By a happy innovation, Colonel J. J. Astor, succeeding Mr. Samuel Courtauld as chairman of the school board, would unite that post with chairmanship of the hospital. Dr. Boldero regretted the circumstances which obliged some of the young men who were to have entered the school this autumn to enter the Forces instead, and he hoped for a change of policy by which military service, if required, would follow completion of the medical course. During the war the school had admitted 80 students a year, and he hoped the number would rise to 100 as recommended by the Goodenough Committee; but this would be impossible until more preclinical accommodation was provided by rebuilding, and until the number of teaching beds could be increased. The board had bought a sizable piece of adjoining land which offered, said Dr. Boldero, "a very real additional opportunity for extension of clinical facilities under our own control." Dr. J. Marks, Broderip scholar, averred that the students had no complaints this year, and their athletic record was very satisfactory. Replying to his health, eloquently proposed by Sir Gordon Gordon-Taylor, the chairman said that his mention of the rowing club's difficulties had caused Sir Alfred Webb-Johnson to promise it a boat of its own.

Medical Diary

OCT. 13 TO 19

Monday, 14th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields W.C.
3.45 P.M. *Prof. A. J. E. Cave*: Anatomy of the Laryn
5 P.M. Dr. F. W. Roberts: Local Anæsthetics.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1
8 P.M. Sir Philip Manson-Bahr: Biological Basis of Medicine. (Presidential address.)

Tuesday, 15th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Dr. E. L. Patterson: Blood-supply of the Brai
5 P.M. Prof. R. J. S. McDowall: Blood-pressure.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.
5 P.M. Dr. I. Muende: Fungus Infections of the Skin

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE
5 P.M. (Royal Infirmary.) Prof. F. A. E. Crew, F.R.S.: of Genetics in Clinical Medicine.

Wednesday, 16th

In future the new quarterly, the *Journal of the History Medicine and Allied Sciences,* will be issued in this coun and the British Empire by William Heinemann Ltd., Lond The subscription in Britain is 50*s.* per annum or 12*s.* per single copy.

A warning against the uncontrolled use of a new dr 'Triodione,' for the treatment of epilepsy, has been issu by the American Medical Association, which states that t deaths have been reported in patients who were treat themselves.

CINOMA OF PROSTATE TREATED WITH ŒSTROGENS *

J. D. FERGUSSON
M.D. Camb., F.R.C.S.
RGEON, CENTRAL MIDDLESEX COUNTY HOSPITAL

E treatment of carcinoma of the prostate by castra- or by the feminising influence of œstrogens has been luced comparatively recently but already seems ole, in many instances, of giving greater relief than methods.

1935 an investigation into the origin of enzymes l in urine led to the discovery that the normal human tate is a prolific source of an acid phosphatase. her observations by Gutman and Gutman (1938) ed that this enzyme is only elaborated in appreciable tity by the mature gland. This significant finding later confirmed by Gomori (1941), who demonstrated hosphatase in adult prostatic epithelium by a special ing method. Subsequent research on pathological rial has established that a high percentage of nomatous prostates also produces large amounts of nzyme.

aggins et al. (1941) considered that these findings it that the majority of carcinomatous prostates con- epithelial cells of a highly differentiated type, capable aborating acid phosphatase. Acting on this assump- and with the knowledge that normal adult prostatic elium could be made to atrophy by removing the genital glands, Huggins advocated castration in treatment of prostatic carcinoma. The synthesis of ogenic substances by Dodds (1938) afforded an native and perhaps more humane method of treat- t; for, by their antagonistic action to androgen, these tances appear to induce a response similar to that ined by castration.

ÆTIOLOGY OF PROSTATIC CARCINOMA

ttle is known about ætiological factors in prostatic inoma, but, so far as I can ascertain, it has never en noted in a eunuch. The prophylactic implications re hardly likely to meet with universal approval, but it is t interest to compare this observation with the effect of astration on the established disease. Unfortunately the rity of prostatic cancer in animals has so far prevented ay confirmatory investigations.

TABLE I—REPEATED BIOPSIES IN PROSTATIC CANCER DURING TREATMENT WITH ŒSTROGENS

ase	No. of biopsies	Intervals between biopsies	Total dosage of œstrogens
1	4	5 months, 16 months, 1 year	6130 mg. S
2	2	30 months	3548 mg. S
3	3	10 days, 17 months	4380 mg. S
4	2	10 months	1792 mg. S
5	2	6 months	500 mg. D
6	2	1 year	1560 mg. D
7	3	39 days, 10 months	1150 mg. D
8	2	9 months	960 mg. D
[illegible]	2	16 days	200 mg. D
10	2*	23 months	4641 mg. S
11	2*	10 months	2326 mg. S

Biopsy supplemented by necropsy. S, stilbœstrol; D, dienœstrol.

VARIATIONS IN PROSTATIC CARCINOMA

The pathology, symptoms, and clinical course of rcinoma of the prostate vary widely. Differences in the cellular arrangements of the tumour are common, all gradations being met with, from anaplastic forms through glandular to scirrhous types. Even in the same prostate the histological appearance is seldom uniform, though this may be due in part to anatomical factors. I am prepared to believe that most growths originate in that portion of the gland lying below and behind the verumontanum; but, from a dissection of many adult prostates, I am now inclined to think that there is no well-demarcated posterior lobe. No part of the prostate need ultimately remain exempt, and in a high proportion of cases the growth is already widespread when detected. Very occasionally the reverse obtains, and a small area of unsuspected malignant tissue may be found in what was considered clinically to be an "adenomatous" prostate.

TABLE II—ACID PHOSPHATASE IN PROSTATIC TISSUE

Source	Acid phosphatase (King-Armstrong units per 100 g. of moist tissue)	
	Lateral lobe	Posterior part
Necropsy:		
Benign glands (6 cases)..	1410 960 8420 1900 2190 9800	4840 14,500 10,900 10,340 11,670 11,500
Biopsy:		
Benign glands (20 cases)	Average 7300; highest 15,600; less than 1000 in 4 cases	
Carcinomatous glands (14 cases)	Average 11,784; highest 28,200; less than 1000 in 1 case	

Differences in the dissemination of metastases are common and explain much of the disparity between general and urological symptoms. In this connexion I would emphasise the frequency of superficial lymphatic metastasis—a point liable to be overlooked.

Variations in the clinical course are determined largely by the metastases, and the disease may sometimes pursue a relatively asymptomatic course for years, only being detected at necropsy.

It is important to appreciate fully such variations before assessing the merit of any treatment.

TREATMENT OF PROSTATIC CARCINOMA

In a review of 1000 cases of prostatic carcinoma, Bumpus (1926) showed that two-thirds of the patients, if untreated, died within a year of coming under observation. If metastases were detected when first seen, this period was reduced to nine months.

With improved methods of treatment the average survival period became somewhat longer, but few procedures gave any constant relief. In some instances the complications of therapy proved a greater affliction than the disease. Many of the methods, however, remain of value, and, with the addition of castration and œstrogen therapy, now constitute the basis of treatment of prostatic cancer. Omitting radical prostatectomy as applicable in only a small proportion of cases, treatment in the remainder falls into three categories:

(1) *Palliation of symptoms by medical means.*—This is entirely non-specific and has no direct application to the growth.

(2) *The surgical relief of urinary obstruction* by urethral dilatation, cystotomy drainage, or perurethral resection. With œstrogen treatment, the indications for cystotomy drainage are becoming less frequent. It remains of value in patients almost moribund from uræmia, and in cases where involvement of the external urinary sphincter leads to incontinence.

(3) *The suppression of neoplastic activity* by radiotherapy, œstrogen treatment, castration, or irradiation of the testes.

It has been the experience of many observers that the addition of castration or œstrogen therapy is often followed by a degree of relief not achieved by other methods. This evidence, though significant in its volume, is necessarily based largely on the subjective statements of patients. A similar criticism may be levelled against the uncorroborated clinical findings of the surgeon, particularly those relating to repeated rectal examinations during treatment. In other words, though in many cases the giving of œstrogens is apparently accompanied by a satisfactory response, such an opinion is often open to the objection of the wish being father to the thought.

---

* Abridged from a Hunterian lecture given at the Royal College of Surgeons of England, June 13, 1946.

METHOD OF INVESTIGATION OF RESULTS OF ŒSTROGEN TREATMENT

Hoping to overcome such criticism, I decided in 1942 to carry out repeated biopsies of the carcinomatous prostate, and of any accessible metastases in suitable cases during continued œstrogen therapy. This method of investigation appeared of additional value in affording a positive control by means of which primary errors in the diagnosis of prostatic carcinoma could be definitely excluded—a risk which might otherwise lead to false claims for œstrogen therapy (Fergusson and Pagel 1945).

My preference for conducting this survey with œstrogens, instead of following the results of castration, was based on a hope that I might also discover the optimum dosage. Further, if such treatment proved ineffective, it would still be possible to resort to operation.

Opinion seems to vary geographically as to the value of retaining the male genital glands, and in many reports from transatlantic clinics a preference is expressed for bilateral orchidectomy. Such treatment is often mitigated and even embellished by the substitution of a plastic prosthesis, but the psychological effect is liable t disturbing. On the other hand, with pro administration of œstrogens the testicular atrophy loss of desire are more gradual and are accepted w equanimity seldom evinced after castration.

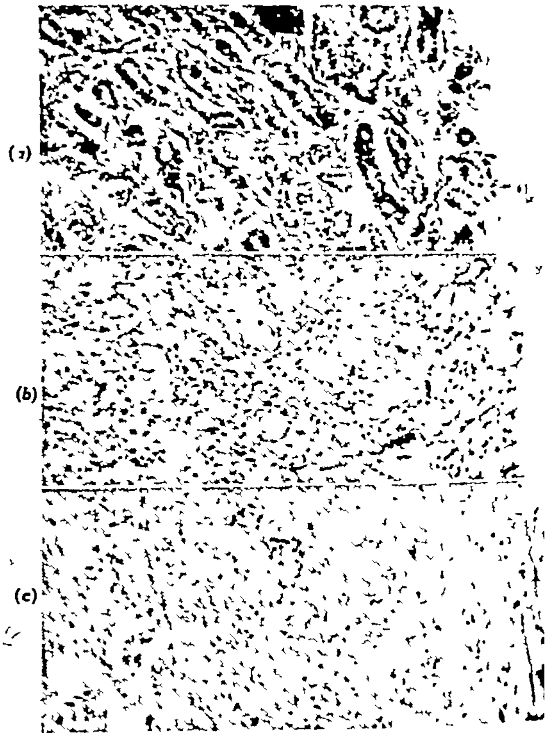

Fig. 2—Serial biopsy specimens of prostatic carcinoma during treatment, showing regression of tumour: (a) initial; 10 days; (c) 17 months later

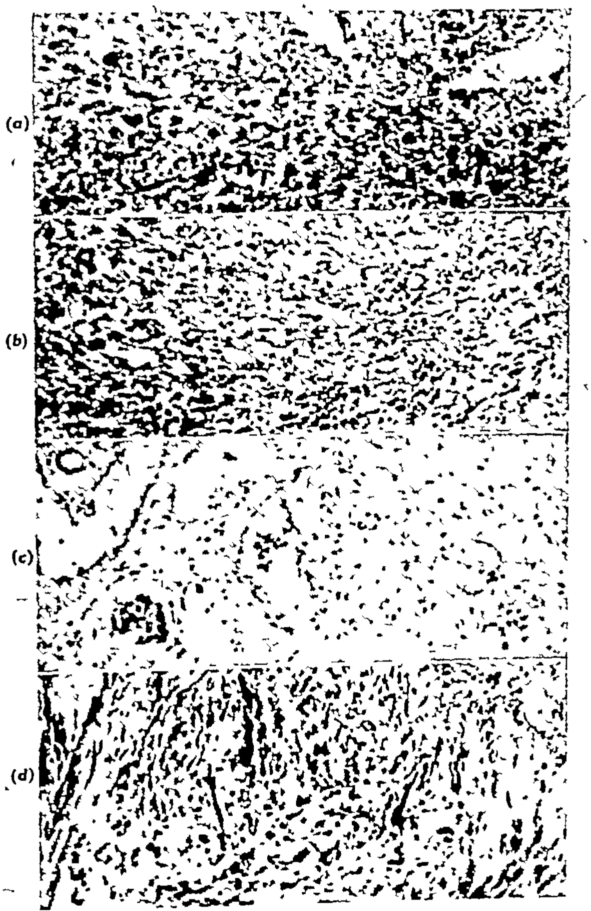

Fig. 1—Serial biopsy specimens of prostatic carcinoma during œstrogen treatment, showing regression of tumour and replacement fibrosis: (a) initial; (b) after 5 months; (c) 16 months later; (d) a year later.

When I started my survey during œstrogen I was unaware of a parallel investigation by Sc et al. (1942) conducted for two months in the U States, but my longer-term results agree closely theirs. I have since been able to corroborat histological findings by simultaneous estimations acid-phosphatase content of the affected tissues.

It was clear from the outset, in view of the variations in the histology of the growth, that comparison of serial biopsy material might be Therefore the following conditions had to be satisfie

(1) All the patients should have a *proved* prostatic In 23 cases treated with œstrogens since 1942 the diagnos confirmed by biopsy in 21, the remaining 2 having indisp clinical, radiographic, and serological evidence.

(2) The patients should preferably show a good response to œstrogens since, if they did not, *no* well-d histological changes could be anticipated. The ideal would thus be one showing relief from pain, increase in and general well-being, but in which a degree of obstruction persisted requiring surgical relief.

(3) Any tissue for comparison should be removed fro same site as far as possible on each occasion, and care to avoid at the first biopsy undue trauma which might the later histological appearances. To satisfy this con I carried out every biopsy with the Gershom Thompson punch" resectoscope, removing tissue from "behin posterior quadrant of the urethra above the verumont I do not believe that there is any great risk of stimu metastatic spread by this technique. Diathermy hæm is reduced to a minimum to avoid subsequent necros bleeding is preferably controlled with a Foley's bag cat A control series of repeated resections of "adenoma prostates made in a similar manner showed neg traumatic reactions.

(4) Enough tissue should be removed on each oc to minimise any error due to vagaries of anatomical str and distribution of the growth.

RESULTS OF REPEATED BIOPSIES

n these lines I carried out repeated prostatic biopsies ine of the cases receiving œstrogens (table I). The rvals between these biopsies varied from 10 days to months, and in a few instances additional biopsies e undertaken over periods extending up to 3 years. inimum of 1·5–2·0 g. of tissue was removed on each asion for examination. In a further two cases, where r preliminary biopsy and initial response to treat- nt the patient later deteriorated, valuable serial terial was obtained at necropsy.

very patient received continuous œstrogen treatment, d any adjuvant therapy was on uniform lines. Œstro- n was administered as stilbœstrol or dienœstrol in ses of 2–15 mg. a day. As each successive biopsy s performed, serial sections were made and stained multaneously for accurate comparison.

The preliminary visual impression on examining the ctions suggested that in nearly all cases the neoplasm s regressing considerably during treatment. The llections of cells forming the tumour units were creasing not only in size but also in number. The neral trend appeared to be away from a glandular enocarcinomatous to a less cellular scirrhous form. his is well exemplified in fig. 1, which shows the histo- gical appearance on four occasions extending over arly 3 years. The photomicrographs are entirely presentative of many serial sections. Fig. 2 shows a milar picture of three biopsies extending over 17 months. In the remaining seven cases similar findings were btained.

A more detailed histological examination was under- ken in several instances, involving a computation of e tumour units in microscopic fields of standard size, nd a measurement of the nuclear diameters of the mour cells, which in the later specimens appeared to e smaller. These examinations were conducted by killed laboratory technicians for whose impartiality and bility I have the highest respect; and the results obtained lly confirmed the original visual impressions. The eduction in average size of the nuclei is shown in fig. 3, here in three cases the nuclear diameters are plotted gainst the number of nuclei.

During the last 18 months it has been possible to ubstantiate these findings by examining half the fresh biopsy material for tissue acid phosphatase. There are two ways of detecting it—biochemical estimation of the enzyme, and demonstration by the lead-nitrate and ammonium-sulphide staining method used by Gomori (1941). The methods seem to give comparable results in that a positive staining reaction visible to the naked eye appears to develop with reasonable uniformity when the concentration of the enzyme exceeds 1000 King-Armstrong units per 100 g. of tissue.

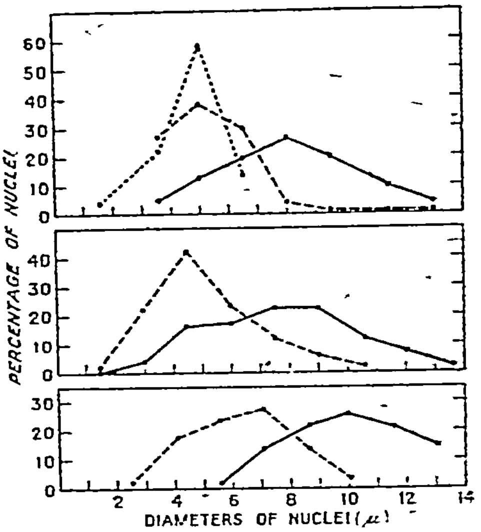

Fig. 3—Decrease in nuclear diameters of tumour cells of prostatic carcinoma during œstrogen treatment: solid lines, diameters at initial biopsy; broken lines, diameters at subsequent biopsies. A shift from right to left denotes reduction in diameters.

When I first tried the staining method I had two objects in view. Besides hoping to find a demonstrable reduction in the amount of enzyme in carcinomatous prostates as treatment progressed, I was anxious to discover whether the amount was greater in the posterior portion of the normal gland, a point which might possibly have a bearing on the frequency of malignant change in this situation. After a considerable number of normal adult prostates had been stained, my findings agreed with Gomori's (1941) view that the quantity and the distribution of the enzyme vary widely throughout the gland.

A few physiological adult prostates do not stain sufficiently to be visible with the naked eye, but in most, despite irregular distribution, there is evidence that a greater concentration of enzyme is common in the posterior part of the gland. This finding may, however, be influenced by potential "adenomatous" changes in the lateral lobes. Fig. 4 shows sections from two benign prostates differing in the distribution of the black-staining phosphatase, but in each case showing a quantity of enzyme in the posterior part behind the verumontanum. (Incidentally, staining of the complete female urethra to detect acid phosphatase has so far given no indication of a prostatic homologue.)

Carcinomatous prostates, on the other hand, generally show a consistently large amount of enzyme throughout their extent. A few quantitative estimations have been made on benign and malignant glands, and table II shows that whenever the whole benign gland was available a greater amount of enzyme was found in the posterior part. In the biopsy material, figures for carcinomatous tissue are slightly above the average for benign glands.

In four of the cases of prostatic carcinoma in which repeated prostatic biopsy was done the histological findings were supplemented by tissue acid-phosphatase estimation. In each case the concentration of the enzyme diminished during treatment, as illustrated in figs. 5 and 6. At the same time quantitative estimations showed decreases in units per 100 g. of tissue as follows: 8000 fell to 200, 3000 to 600, 8000 to 100, and 28,000 to 2000.

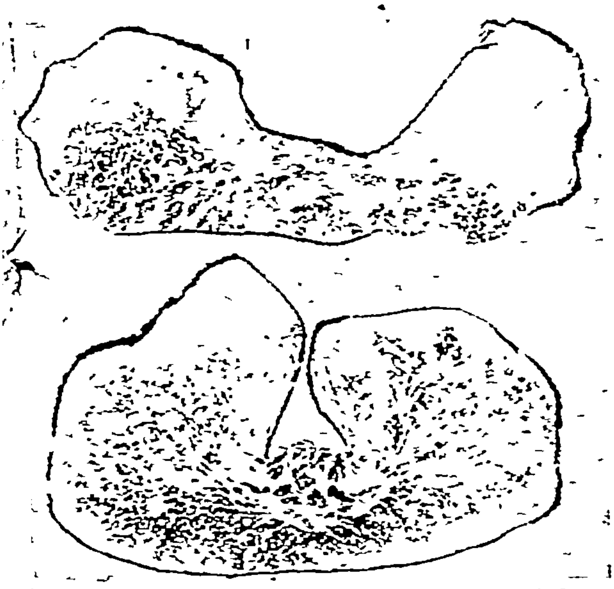

Fig. 4—Transverse sections of adult benign prostates, at level of verumontanum, stained to show acid phosphatase. Notice increased amount of enzyme in posterior part of gland.

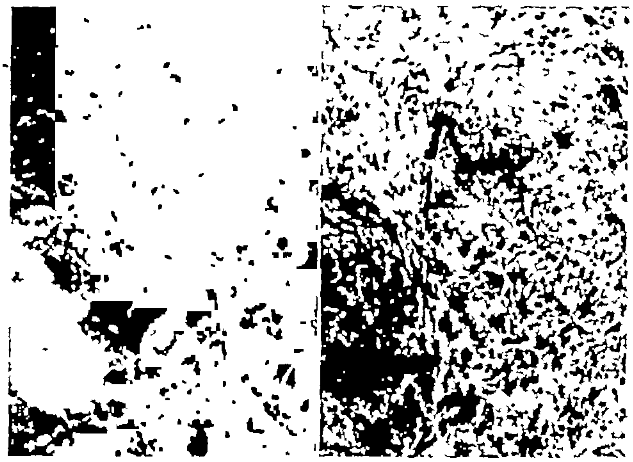
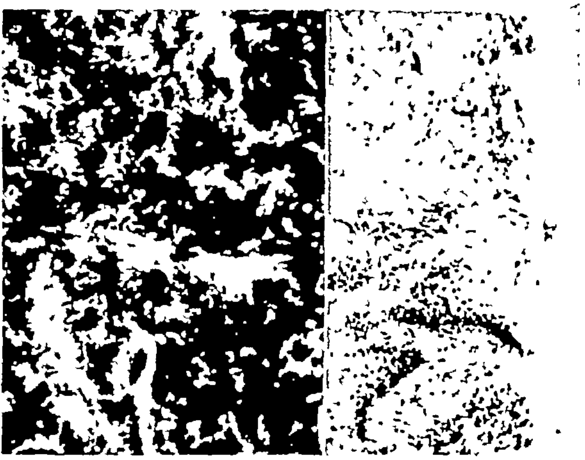


(a) (b)

Fig. 5—Serial biopsy specimens of prostatic carcinoma during œstrogen treatment, stained to show decrease in amount of acid phosphatase: (a) initial; (b) after 8 months.



(a) (b)

Fig. 6—Serial biopsy specimens of prostatic carcinoma during œstrogen treatment, stained to show decrease in amount of acid (a) initial; (b) after a year.

These investigations indicate that, in some cases of prostatic carcinoma showing a good clinical response to œstrogens, there is a well-defined improvement in the condition of the primary growth, as shown by the histological changes and corresponding reduction of tissue acid phosphatase. This accords with the clinical finding that the prostate appears, on rectal examination, to lose some of its malignant characteristics. I hasten to add that some cases of prostatic carcinoma do not seem to respond to œstrogens, and that, apart from anaplastic forms as noted by Sullivan et al. (1942), I have been unable to correlate this failure with any particular histological picture.

Another point of importance is that there is no intimate connexion between the concentration of acid phosphatase in the affected prostate and the amount in the blood-serum. The serum value undoubtedly derives from the quantity elaborated by metastases as well as by the primary growth. Out of 50 cases of prostatic carcinoma treated since 1940, the serum value exceeded 3 units per c.cm. in 90% of 39 patients with radiological metastases.

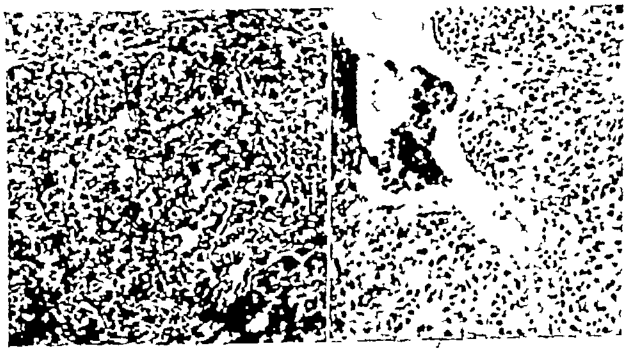
BEHAVIOUR OF METASTASES

Though most metastases from prostatic carcinoma are not readily accessible for histobiochemical investigation, superficial lymph-nodes are not uncommonly involved. The opportunity, however, seldom presents for comparative study of these affected tissues, since this would presuppose identical malignant involvement of at least two glands at the outset.

So far as clinical evidence is allowable, one of my did comply with this condition. The patient had affected glands in the right axilla, similar in size and consistence, and showing equal clinical evidence of carcinomatous involvement. One gland was removed at the start of œstrogen treatment, and the other, which became noticeably smaller and softer, 24 days later. The microscopical findings are depicted in figs. 7 and 8, which show that the second gland exhibits less malignancy and contains a much smaller concentration of acid phosphatase. Normal lymph-glands show no acid-phosphatase staining reaction. This comparison is undoubtedly open to criticism, but, taken in conjunction with clinical evidence in other cases, gives reason for the belief that œstrogens may produce a beneficial, if temporary, effect on metastases.

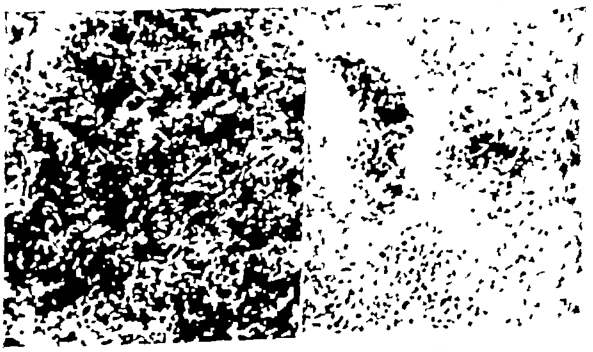
No further opportunity for comparison has yet arisen, but in several other cases I have carried out phosphatase staining on solitary lymph-glands affected with prostatic cancer. In every case where the primary growth showed a positive staining reaction the gland did likewise.

I then tried to discover whether secondary involvement from other types of primary growth was accompanied by acid-phosphatase production, and to decide whether glandular biopsy with phosphatase assay would be of any value in diagnosis. Many lymph-glands affected by various pathological processes, including malignant disease, were examined, but acid phosphatase was rare except in secondary prostatic carcinoma. It was noteworthy that several tuberculous glands gave a



(a) (b)

Fig. 7—Sections from two similar axillary lymph-glands, affected by metastases from prostatic carcinoma, during œstrogen treatment. Gland (b) was removed 24 days after gland (a) and appears less malignant.



(a) (b)

Fig. 8—Same sections as in fig. 7, stained to show acid phosphatase. Gland (b) has le[illegible] than gland (a).

cate staining reaction, and I suspect this may be cted with subsequent calcification (fig. 9). Of nalignant glands examined, only two, apart from . affected by prostatic carcinoma, gave a positive ion. These were glands secondarily affected by noma originating in the stomach in one case, and in penis in the other.

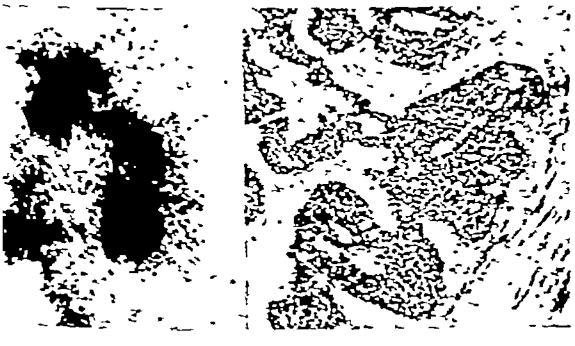
seems therefore that the presence of much acid -phatase in a secondarily affected gland strongly gests a primary growth in the prostate, but does not ve it.

SIDE-EFFECTS OF ŒSTROGEN THERAPY

Iost of the side-effects of œstrogens, particularly in ge doses and over long periods, are relatively harmless, l in several instances I have used dienœstrol 40–50 mg. ly without adverse results other than occasional miting.

Changes in the male breast appear in about two-thirds the cases. There may be tenderness of the nipple a, diffuse mammary swelling, and pigmentation. mentation is usually confined to the areola but may ely involve the surrounding skin (fig. 10). The breast anges do not seem to bear any constant relation to the ostatic response.

Shrinkage of the testes and *diminution of sexual feeling* ve taken place in about a quarter of my patients but ve been accepted with equanimity. Microscopy of ch testes shows no special changes beyond those sociated with senile atrophy. (I have incidentally und œstrogen therapy of considerable value in cases benign so-called prostatism associated with sexual errations.)



(a) (b)

g. 9—Sections of (a) tuberculous lymph-gland and (b) lymph-gland affected by metastasis from prostatic carcinoma, both stained to show acid phosphatase. Note amount of enzyme in (a).

Change in Complexion.—Though I have been unable detect any conspicuous loss of hair in my patients, it as been pointed out to me that many who have received rolonged treatment develop a choir-boy countenance.

Vertigo.—Apart from these minor side-effects and oradic mild skin rashes and œdema, the only thera-eutic complication which I thoroughly respect is vertigo. everal cases have been recorded in which patients died f a cerebral castastrophe, and I have had one such case. t is difficult to ascribe such an event to the giving of strogens, particularly in elderly patients, but I have the mpression that vertigo may be the precursor of this isaster. How far it is vascular in origin, and thus ossibly akin to the spasmodic vascular affections of emales, is a matter for speculation.

On the whole it may be said that, compared with many ther methods of treatment for prostatic cancer, œstro-en therapy seldom has disturbing sequelæ.

RESULTS OF TREATMENT

Of 50 cases of prostatic cancer which I have treated uring the last six years, 27 were treated on standard lines without œstrogen, and the remaining 23 received, in addition, continuous œstrogen therapy. I have excluded any cases of more recent date than December, 1945. From this small series, observed over a relatively short period, no conclusions are justifiable in respect of cure, but the survival-periods are interesting (fig. 11). Many of the surviving patients are in good health and appear likely to remain so for some time to come.

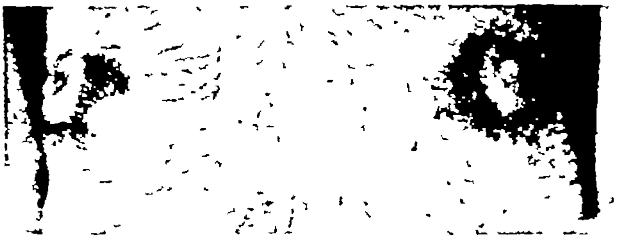


Fig. 10—Circumareolar pigmentation of male breast in patient receiving œstrogen treatment.

DISCUSSION

Roughly speaking, patients dying during œstrogen treatment can be divided into three classes:

(1) Patients who are moribund or in an advanced stage of renal failure when treatment is begun.

(2) Those who, though otherwise apparently eligible, show no reaction to œstrogens, and in whom the natural course of the disease proceeds unchecked. Probably many such patients have anaplastic tumours, possibly of a type that does not produce acid phosphatase.

(3) Patients who show a satisfactory initial response, as judged clinically, biochemically, and histologically, in whom a delayed and often sudden relapse takes place, as if all sensitivity to œstrogen was abruptly lost.

About half the deaths in the group receiving œstrogens fall into this last category of delayed reactivation of the growth. At necropsy in three of such cases almost complete regression of the primary prostatic growth was found, despite the coëxistence elsewhere of widespread metastases, many of which, from clinical evidence, were of recent origin. In all these cases prostatic biopsy at the start of treatment had shown a highly active primary growth. A similar finding after castration has been reported in the United States by Huggins (1942) and by Gilbert and Margolis (1943). One is reminded forcibly of the observations of Prym (1925) on the spontaneous inactivation of primary chorionepithelioma of the testis in conjunction with spreading metastases, and of the sporadic success of oöphorectomy performed for mammary cancer.

Two questions arise:

(1) Is this peculiar behaviour limited to neoplasms of the sexual apparatus? If so, may it not be possible that the action of œstrogen is physiological, primarily affecting the organ in which the growth arises?

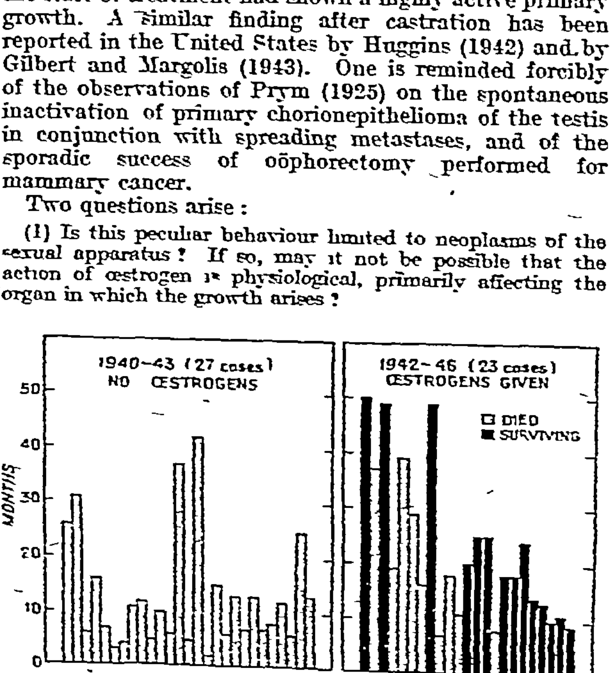

Fig. 11—Survival periods of patients with carcinoma of prostate, with and without œstrogen treatment.

vaccine bottles. So far no loss of potency has been demonstrable, even in antigen kept at room temperature for six months. Before general use each batch of antigen is tested on a known positive subject and a known negative subject.

Since human-type cercariæ from physopsis have been used exclusively, it is probable that the antigen is composed largely of *S. hæmatobium* products; but we feel, on epidemiological grounds, that these snails must be acting as intermediate hosts of *S. mansoni*, and we intend to investigate this question later. For the purposes of the skin-test the question is of academic interest only, since all workers agree that there is a common antigenic factor in the schistosomes.

PERFORMANCE OF TEST

We use the ordinary intradermal technique, with a tuberculin-type syringe and a fine-bore short bevelled needle. Influenced by Coca (1931), we inject as little of the antigen as possible, the aim being to use a dose of 0·01 c.cm., which usually raises a weal 3–5 mm. in diameter. The injection is made into the skin of the flexor surface of the forearm, choosing if possible an uninjured hair-free area. The importance of securing a true intradermal injection cannot be over-emphasised. If a small intradermal bleb is not obvious when the needle is withdrawn, the injection should be repeated at once in another place.

In view of suggestions that phenol per se may produce non-specific positive reactions in intradermal tests for trichiniasis (Spaeth 1942), we made control injections of carbol-saline in 200 of our cases. They included both positive and negative reactors to the antigen, but no positive reactions to the carbol-saline injection were seen.

We have been careful not to use ice-cold antigen direct from the refrigerator, since it is believed that false positives due to cold allergy may be encountered.

READING OF TEST

The reaction of the skin to the intradermal injection of the antigen is observed at 10, 15, and 20 min. In the *negative reactors* the original weal may disappear so completely that only the injection prick enables the site to be located. In other negative reactors the weal has not entirely disappeared at the end of this period but is certainly no larger than the original weal. Erythema is of no significance and is often seen in young children and women.

The commonest type of *positive reaction* is the formation of a disk-like button-weal which appears to be raised above the level of the normal skin. The elevation of this weal is often more apparent to touch than to sight. The increase in size of the weal varies enormously, and a weal 25 mm. across has been observed. In many positive reactors a ninefold increase in weal area is seen. Another type of weal commonly seen is characterised by an irregular outline and the pushing out of "pseudopodia" into the surrounding skin. In white-skinned positive reactors erythema round the weal can also be seen. In the flat type of weal it is often necessary to grasp the dorsum of the forearm and stretch the skin of the flexor aspect to blanch the erythema which may mask the outline of the weal.

LATE REACTIONS

We have no first-hand information about late reactions as described by Risquez and Boza (1941)—in fact, we have not had described to us any reaction at the site of injection. One patient described a transient œdema of the fingers of the arm into which the injection was made; he was a negative reactor, and the alleged œdema occurred six hours after the test. Another patient, a boy who was a positive reactor and in whom eggs of *S. hæmatobium* were subsequently found in the urine, developed, mainly on the trunk, ten days after injection, a scarlatiniform rash sufficiently sever cause his parents to call their doctor. The rash in twenty-four hours.

MATERIAL AND RESULTS

We performed skin-tests on three population grou European schoolboys aged 12–17 years, Eurafr schoolboys aged 7–17 years, and African young males enlisted in the S. Rhodesian native regiment, total of 592 subjects. Urine and stool specimens obtained from each subject at the time of testing, instructions having been issued on the best method collection. Further stool and urine specimens examined from all skin-test positive cases until sets of specimens had been obtained, or until eggs demonstrated. Some of the subjects defaulted in submission of specimens. The results are summarised tables I and II.

It is difficult to obtain reliable histories of previo treatment from Africans and the Eurafrican children These children particularly were so unreliable that no attempt has been made to classify treated and untreated The African treated group, however, had all receive treatment in the Army in 1943–45. The treated group of European boys had been treated by private practitioners in 1940–45. All the cases shown as positive were passing at least a proportion of viable eggs

There appears to be a significantly higher percentage of active infections in the treated than in the untreated European schoolboys. Whether this is due to insufficient

atment or to liability to reinfection on returning to eir usual environment, we do not know. One boy, ed 16 years, gave a history of no fewer than seven urses of antimony in the past eight years, and is still ssing viable eggs of *S. mansoni*.

DISCUSSION

Value of Negative Result of Test.—The tables show that e have not encountered a negative skin reaction in a atient who passes schistosome eggs. It must be admitted at many of the negative skin reactors have only been xamined once, and by our own showing single examiations of excreta for eggs are unsatisfactory. Nevereless we feel that in the many hundreds of controlled xaminations we would have at some time encountered uch a phenomenon if the test were not sufficiently ensitive. We therefore think it justifiable to assume reedom from infection in patients who have no skin eaction. In a country where schistosomiasis must be onsidered in all obscure and indefinite illnesses such an xclusion test as this will be of great value to clinicians and laboratory workers alike. In mass-treatment campaigns it can reliably be used to weed out the non-infected. We have already discussed the varying district incidence of schistosomiasis in Southern Rhodesia, and such a rapid "screening" will be of the utmost importance in saving drugs, material, staff, and time.

Value of Positive Result of Test.—In the earlier work carried out by one of us, the antigen could be used only on a small scale, and it was decided to attempt to assess the antigen by skin-testing hospital patients passing eggs. These patients, 90 in all, had positive skin reactions.

Table I shows that we have not succeeded in completely correlating positive skin-tests with the passage of eggs in the excreta. Nevertheless, the follow-up data indicate that the gap lessens as the number of repeat examinations is increased. We have not been able to do as many repeat examinations as are desirable; patients are lost sight of or may become reinfected. In any case we believe that there must always remain a hard core of infected persons whose infections will never be diagnosed by microscopical methods and in whom proof will be forthcoming only at operation or necropsy.

We would, however, cite our experience in examining a group of 50 children as opposed to adults. These children were Eurafricans in an orphanage. Of the 50 children examined, 25 were skin-test positive, and on the first examination of their excreta 16 infections were diagnosed. On the first re-examination of the remaining 9, 2 more infections were discovered; on the second re-examination of the remaining 7, 2 more were found; and on the third re-examination of the remaining 5, 1 more infection was diagnosed. A fourth re-examination did not reveal any further infections, but blood-counts revealed eosinophilia in all of the 4 remaining cases.

In our opinion the patient who presents a suggestive history and has a positive skin reaction, and in many cases an eosinophilia, should be given specific treatment. Positive reactors seen in mass investigations should also receive treatment. Some of these patients may not be infectious in that they are not passing eggs, but the debilitating and damaging effect of this disease would justify their treatment on public-health and economic grounds.

Value of Skin-test in Treated Cases.—Treated cases may be placed in one of several categories:

(1) Patients who can be shown to be passing viable eggs soon after a course of treatment, when sufficient time for reinfection has not elapsed. We have seen several such cases; they are all skin-test positive.

(2) Patients who cease to pass viable eggs but whose clinical condition shows only a transient improvement. This failure to maintain improvement may be due to two factors: tissue damage may have been so extensive that it cannot be ameliorated by drug therapy alone; or all the worms in the body have not been killed.

Fairley et al. (1930) present evidence that, in experimental infections, male worms are more resistant than females to treatment with tartar emetic. Fairley (1924) records positive complement-fixation tests in patients who have been treated with tartar emetic and are passing no eggs, and he later (1926) postulated the survival of the more resistant male worms.

Many of our patients who have received by ordinary standards an adequate course of treatment fall into the second group; their skin-tests are positive. On the other hand, patients are met whose skin-tests are negative but whose clinical condition remains unsatisfactory.

(3) Patients who cease to pass eggs and whose clinical improvement is maintained and whose skin reaction becomes negative. In our series of 100 cases treated with intensive antimony (Alves and Blair 1946) many such cures were obtained. It was possible to demonstrate in some of these a negative skin reaction two months after the cessation of treatment, whereas others showed negative reactions after three months. This reversion to negative after two months probably represents too rigorous a standard for clinical application, but we have no reason to believe that in a cured case the skin reaction will remain positive after a period much in excess of this.

We therefore suggest that further treatment is needed in cases showing positive skin reactions six months after treatment. We have been much impressed with the apparent failure of the ordinary course of antimony and sodium tartrate to cure even those subjects who coöperate completely in adhering to the prescribed routine.

The several groups of treated cases may therefore be summarised as follows:

(1) *Complete Failures.*—Passage of viable eggs, no improvement in clinical condition, positive skin-test. Further treatment indicated.

2. "*Public-health*" *Cures.*—No eggs passed, possible clinical improvement, positive skin-test. In mass campaigns no further treatment.

3. *Partial Failures.*—(*a*) No eggs passed, possible clinical improvement, positive skin-test; further treatment indicated for the individual patient. (*b*) No eggs passed, little or no clinical improvement, negative skin-test; further drug treatment useless.

4. *Perfect Cure.*—(*a*) No eggs passed, clinical improvement manifest, negative skin-test. (*b*) Passage of dead eggs,

possibly for considerable periods after cessation of treatment; clinical improvement and negative skin-test.

SUMMARY

Routine microscopy in the diagnosis of schistosomiasis is inaccurate and expensive.

The preparation and use of a cercarial antigen for intradermal testing is described.

A higher proportion of cases of schistosomiasis is revealed by this antigen than can be detected even by repeated microscopical examinations.

The efficiency of treatment of this disease can be measured more accurately with the skin-test.

Since no negative skin reactors have been found to be passing eggs, the test can be used as a rapid and accurate "screen" in mass-treatment campaigns.

Its use in indicating the need for further treatment is also outlined.

Our thanks are due to Dr. A. P. Martin, O.B.E., medical director, Southern Rhodesia, for permission to make this communication.

PENICILLIN IN INFANCY AND CHILDHOOD *

JEAN L. BUCHANAN
M.B. Glasg.

From the Royal Hospital for Sick Children, Glasgow

PENICILLIN can be given to infants and young children (1) by continuous intramedullary, intramuscular, or intravenous drip; (2) by intermittent intramuscular injection; or (3) by mouth.

Injection into the bone-marrow near the lesion has been successfully used in acute osteomyelitis (Aird 1945). Alternatively, the sternal marrow may be used. But intramedullary injection or infusion carries a risk of infecting the marrow with penicillin-insensitive organisms and ought not to be undertaken without skilled supervision.

Intravenous injection presents special difficulties in young patients because their veins are small and readily thrombosed; and since the veins may later be required for blood-transfusion it is inadvisable to cut down on more than one. Also children need frequent nursing attention which tends to displace the needles, with added risk of infection.

Despite nursing difficulties, continuous intramuscular injection by drip is the method preferred in the surgical wards of the Royal Hospital for Sick Children, Glasgow, for patients over the age of 2 years. Since children's small muscles have a limited power of absorption and less resistance to infection than adult tissues, particular care must be taken not to distend them and to avoid infection at the site of the needle-punctures.

The standard dose for the intramuscular drip in this hospital is 100,000 units per 24 hours, and the apparatus used is the 'Eudrip' no. 3 (McAdam et al. 1944). With this dose the blood-penicillin level is usually adequate, but occasionally, when the infecting organism is penicillin-resistant, dosage is doubled, and in ex cases it may even be increased to 500,000 units hours. Table I shows the maximum dilutions of producing complete inhibition in eleven cases from various age-groups and receiving penicillin 100 units per 24 hours by continuous intramuscular drip. The slide-cell method of estimating the level of serum inhibition was used (Bigger et al. 1944), and the test organism was the Oxford staphylococcus. Complete inhibition in a serum dilution of 1 in 32 was accepted as equivalent to 1 unit of penicillin per c.cm. of the patient's serum.

TABLE I—MAXIMAL DILUTIONS OF SERUM PRODUCING CO INHIBITION IN CASES RECEIVING PENICILLIN 100,000 U PER 24 HR. BY CONTINUOUS INTRAMUSCULAR DRIP

11	10	1 in 2

* Serum diluted with broth.

In the medical wards of this hospital intermittent intramuscular injection and oral administration are employed for infants and young children. Bodian (1945) advocated injection into muscle of 1000 units per lb of expected body-weight per 24 hours in divided doses at 3-hourly or 4-hourly intervals, and obtained complete bacteriostasis in undiluted serum up to 4 hours after injection in only 60% of children. It is generally accepted that the basic principle of penicillin therapy is to maintain a minimum therapeutic level constantly in the blood, and Garrod (1944) and Kolmer (1945) consider inhibition in undiluted serum adequate. Our experience showed that penicillin 1000 units per lb. of body-weight per 24 hours was often insufficient to attain this, even in young infants in whom, presumably owing to inefficient excretion by kidneys not yet fully functioning, the blood-penicillin level tends to be higher than in other age-groups. Accordingly the dose was doubled, and further blood tests were performed. Fig. 1 shows that 2000 units per lb. per 24 hours maintains inhibition in undiluted serum. Since, however, occasions might arise where higher levels would be desirable—e.g., in infections with less sensitive organisms—experiments were undertaken with 4000 units per lb. of expected body-weight per

* Work done during the tenure of a McCunn scholarship.

ours. Fig. 2 shows results resembling those in fig. 1, with the blood-penicillin level better maintained. ordingly, we regard 4000 units per lb. of expected ly-weight per 24 hours given intramuscularly at ourly intervals as the optimum dose. This view forms to the latest recommendation on adult dosage udson et al. 1946, Agerholm and Trueta 1946) and persedes the 1000 units per lb. originally suggested the standard adult dose by Florey (1944).

Since penicillin is relatively non-toxic, the optimum se may be exceeded for ease in dispensing. For ample, in this hospital the practice is to maintain in e ward refrigerators solutions of penicillin in strengths 5000, 10,000, and 15,000 units per c.cm., and of 25,000 d 50,000 per 2 c.cm., prepared in phials or ampoules the laboratories with pyrogen-free sterile saline. For ildren under the age of 3 months 5000 units is given ght times a day by injection or by mouth, and for ildren aged 3–6 months 10,000 units eight times a day injection. These doses correspond approximately to 4000 units per lb. of normal body-weight per 24 hours. Though an adequate serum-penicillin level can be reached by 3-hourly intramuscular injections, the repeated punctures, with risk of infection, are a disadvantage, especially in infants and young children, and it seemed advisable to reduce the frequency of injection if this could be done without therapeutic loss. Accordingly 6-hourly injections of 25,000 units were given to children under the age of 2 years, and 50,000 units to those aged 2–5 years. This dosage approximates to 5000 units per lb. of expected body-weight per 24 hours and maintains a constant therapeutic blood-penicillin level. Turner (1944) also found 6-hourly injections satisfactory in infants and children, and Fleming et al. (1944) recommend 6-hourly injections of large doses. Table II shows the blood-penicillin levels obtained by this method.

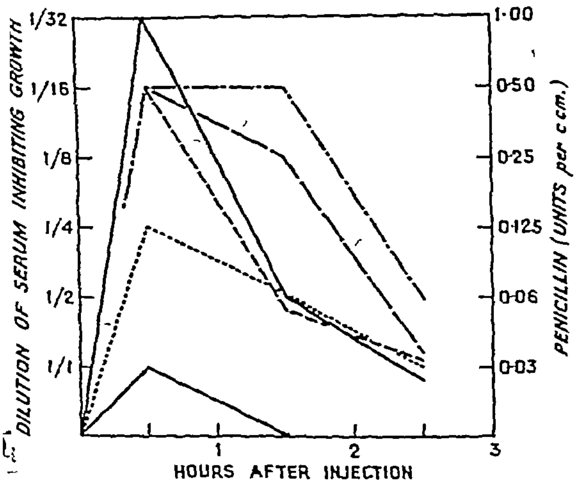

Fig. 1—Blood-penicillin levels of children having 2000 units per lb. of expected body-weight per 24 hours by intramuscular injection at 3-hourly intervals.

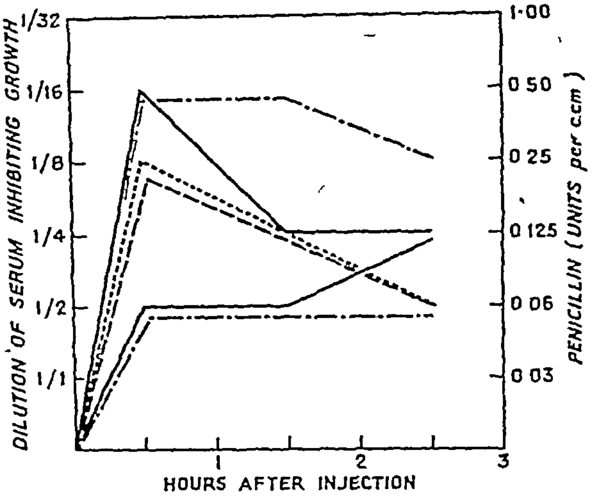

Fig. 2—Blood-penicillin levels of children having 4000 units per lb. of expected body-weight per 24 hours by intramuscular injection at 3-hourly intervals.

ORAL PENICILLIN

Administration by mouth, if proved as effective as intramuscular injection, would make penicillin therapy simpler for the doctor and the nurse and less trying for the patient. In adults it has been demonstrated that oral administration is practicable, at least in infections with the most sensitive organisms, but only by expenditure of four or five times the amount of penicillin needed systemically.

Since Rammelkamp and Helm (1943) have noted that saliva, succus entericus, and bile do not exert a destructive effect, the main inactivating factor is the acid of the stomach (Abraham et al. 1941, Rammelkamp and Keefer 1943). Levinson and MacFate (1937) and Miller (1941, 1942) investigated the gastric juice in infancy and found low acidity, both total and free, except in the first few days after birth. Acidity, which then approximated to the adult level, did not again reach that level until the age of 3 years. The degree of free acidity appears to be correlated with the birth-weight, and a large proportion of the premature infants investigated had achlorhydria. It has been found in this hospital (F. M. Earle, personal communication) that, as a general rule, infections materially reduce the amount of free hydrochloric acid in the gastric juice. In view of these facts, it was considered feasible to explore the possibilities of oral administration to babies under the age of 6 months—the age-group in which a method other than intramuscular injection is most desirable.

A series of 25 babies was investigated, some in the sick nursery of the Royal Maternity Hospital, and others in

TABLE III—LEVELS OF SERUM INHIBITION AFTER ORAL PENICILLIN

the Royal Hospital for Sick Children, most of the infants being in the first month of life. The penicillin was given in the first $^1/_2$ oz. of the 3-hourly or 4-hourly feed, in the dosage of 4000 units per lb. of expected body-weight per 24 hours. The first 4 babies were healthy, and the penicillin by mouth was experimental. In the other 21 babies penicillin was given therapeutically for various neonatal infections. The immediate clinical results of oral administration were on the whole striking, though there were a few relapses which responded to prolonged treatment. Two cases of clinical jaundice with liver enlargement did not respond to oral penicillin but improved on changing to parenteral penicillin. The blood-penicillin levels after oral administration in this group of infants are recorded in table III.

These results show serum-penicillin levels at least as good as those obtained by intramuscular injection—in fact in many cases inhibition is maintained longer. This, as has been mentioned, is due mainly to the fact that the kidney of the very young infant, especially the premature infant, is relatively inefficient (McCance and Young 1941). Probably the adult type of function is not acquired until the end of the first year of life.

It may therefore be said that administration of penicillin in feeds to infants, especially to premature babies, gave results both clinically and serologically comparable with those following intramuscular administration.

The number of babies and premature infants is too small to warrant detailed analysis, but there is no doubt of the striking clinical improvement in the children to whom penicillin was given by mouth. Most of the infections were respiratory and, though the causal organisms, owing to the difficulty of obtaining material, were not identified, the exhibition of penicillin was followed immediately by a fall in temperature, an increase in weight, and improvement in general nutrition. Ross Couper (1945) has already published equally favourable clinical findings.

Oral administration to older children, in whom free hydrochloric acid is present in the gastric contents, is a problem similar to that of its administration to adults. Many vehicles have been used for this purpose (*Lancet* 1945). Experience in this hospital has been limited to penicillin-in-egg mixture (Little and Lumb 1945) and to penicillin combined with aluminium hydroxide (Welch et al. 1945). The former proved nauseating; and, though it was possible to achieve adequate serum-penicillin levels with repeated loading doses of the aluminium-hydroxide mixture, the results on the whole were inconsistent.

SUMMARY

Using intramuscular injections of penicillin, 2000 units per lb. of expected body-weight per 24 hours is required to maintain constant bacteriostasis, with the standard Oxford staphylococcus as the test organism.

It is recommended, however, since infecting organisms vary in their penicillin sensitivity, and to leave a margin of safety, that for general therapy this dose should be doubled.

In infants under 6 months, owing to the low hydrochloric acid content of the gastric juice, penicillin can be administered satisfactorily by mouth in feeds.

Penicillin 4000 units per lb. of expected body-weight per 24 hours given orally to infants has yielded results clinically and serologically comparable to those obtained by injection and should be the method of choice.

I wish to thank Dr. G. L. Montgomery and Dr. K. J. Guthrie for their help both in the work involved and in the preparation of this paper; Dr. Stanley Graham for his valued advice and criticism; and Dr. F. M. Earle for permission to quote some results of her work.

THE clots formed by normal whole blood, or recalcified citrated or oxalated plasma, will re intact in their own serum for days, or even week bacterial growth is prevented. In certain circumsta however, this stability is lost, so that soon after coag tion they break up and disappear. This phenomen called by Dastre (1893) "fibrinolysis," was until re mainly of academic interest; now there are indicatio that it may prove to be a manifestation of a fundamental physiological process.

Nolf (1905, 1908), one of the principal workers on th subject, produced fibrinolysis experimentally in by complex procedures involving hepatectomy a peptone shock. Later (1921, 1922) he studied th fibrinolytic activity that can be produced in plasma b treatment with chloroform "in vitro." He conclud that the fibrin was digested by the proteolytic actio of thrombin, an agent considered by him to consist o two factors ("thrombozyme and thrombogen") who proportions determined proteolysis. Part of this co clusion is supported by the work of Tagnon et al. (194 who confirmed the early observation of Delezene an Pozerski (1903) that chloroform-treated plasma becom capable of digesting casein and gelatin, and related th proteolytic activity to the destruction of fibrin an fibrinogen by such plasma. They considered that a enzyme resembling trypsin is liberated in some way b chloroform, but *that it is not thrombin.*

Recently a new aspect of the process has been reveal by Kaplan (1944), Christensen (1944, 1945), and Christensen and MacLeod (1945). They have shown that the familiar fibrinolytic power ascribed to cultur filtrates of certain strains of β-hæmolytic streptoco is actually due, not to direct action of the filtrate on th fibrin, but to its activation of an enzyme precur present in normal plasma and likely to contaminate th usual preparations of fibrin. Christensen and MacLe (1945) have found that the enzyme so activated, thou proteolytic, is not trypsin. It is associated with th

ulin of the plasma, and is apparently identical with enzyme activated by chloroform. They suggest name "plasmin" for the enzyme, "plasminogen" its inactive precursor, and "streptokinase" for the terial activator. A fourth component must be added these. It has long been recognised that normal sma or serum contains an antiproteolytic factor lezene and Pozerski 1903) associated with the albumin ction (Opie and Barker 1907). This factor is probably cerned with the absence of fibrinolysis in normal ood, and may be called, for convenience, "antiasmin."

The recognition of these components of a proteolytic stem existing in normal blood greatly facilitates an proach to the problem of spontaneous fibrinolysis in an. It is most probable that the disappearance of brin in blood taken after sudden death (Yudin 1936), auma (Macfarlane 1937), or burns and hæmorrhage agnon et al. 1946) is due to the activation of this stem. The possible significance of such a process ecomes the more apparent when it is realised that the lasminogen of normal blood is of a potential activity ufficient to destroy the total fibrinogen of the body in a w minutes, and the more interesting since it is pparently associated with the problematical condition f "shock." Further investigation is desirable, and ight be divided into studies of three aspects of the roblem—first, the interaction of the plasma factors ulminating in fibrinolysis; secondly, the nature of the hysiological process that activates the proteolytic ystem; and thirdly, the effect on the living subject f the proteolytic enzyme when present in the bloodtream. The present paper describes some observations n the first of these. Later publications will be concerned ith the other aspects.

EXPERIMENTAL TECHNIQUE

A first necessity in the study of the inter-relations of lasminogen, antiplasmin, and plasmin is a method for the quantitative assay of plasmin. Since this is a proteolytic enzyme, it would have been desirable to measure its activity by determining the rate of digestion of a pure substrate such as gelatin or casein. Fibrinolysis, indicated by the disappearance of a fine clot formed by the action of thrombin on dilute fibrinogen, has proved, however, to be a far more sensitive index of plasmin activity than protein degradation. In human material, activity, though present, may be so low that fibrinolysis is the only demonstrable effect, and in consequence it has been adopted as the indicator in these experiments. It has the disadvantage that only the presence or absence of the clot can be determined; the extent of partial lysis cannot easily be measured with any reliability. Plasmin activity could therefore be assessed either in terms of the time required for the lysis of a certain amount of fibrin, which is inconvenient, or by determining the greatest dilution of the sample that will lyse an amount of fibrin in a given time. The latter has been adopted here, though it was realised that other reactants besides plasmin would be involved in the dilution, which might lead to complications. As will be seen, complications did arise but were themselves of interest.

The basic technique was as follows. Blood obtained by venepuncture was mixed with 1/9th of its volume of 3·8% sodium citrate solution and spun in the centrifuge at 2500 r.p.m. for 10 minutes; the plasma was then separated. The plasma was diluted with twice its volume of buffer-merthiolate-saline* containing any agent required. After any other necessary treatment 9 serial twofold dilutions of the mixture were made using a 0·1% solution of fibrinogen prepared by the method of Milstone (1941) in the buffer mixture. Three volumes of each dilution were placed in a Wassermann tube and one volume of thrombin solution† added to each tube of the series. Clotting took place in about 30 seconds, and was firm enough to allow the tubes to be inverted without spilling. The final dilutions of the plasma were 1 in 4, 1 in 8, 1 in 16, and so on, to 1 in 2048 in the 10th tube of the series. Assuming that the fibrinogen content of the original plasma was about 300 mg. per 100 c.cm., the fibrinogen concentration in each tube was approximately constant at 75 mg. per 100 c.cm.

After 24 hours' incubation at 37° C. the contents of the tubes were examined for lysis of the fibrin. The end-point was usually sharp, one tube containing an intact clot, the next in the series nothing but clear fluid and a slight amorphous precipitate.

"Chloroform plasma" was prepared by the method of Tagnon et al. (1942) and then treated as described. "Active plasma"—that is, plasma showing spontaneous fibrinolytic activity—was obtained from suitable subjects.‡ The "globulin" fraction was separated by dialysing plasma against moving distilled water in the cold for 24 hours, bringing its pH to 5·5 (estimated by the glass electrode) with $N/10$ acetic acid, and separating the precipitate. The precipitate was then washed with distilled water saturated with CO_2, and finally dissolved in a volume of buffer mixture equal to the original volume of plasma. The "albumin" fraction remained in the supernatant fluid after separation of the globulin precipitate at pH 5·5. The last traces of the latter were removed by spinning at 4000 r.p.m. for 15 minutes, and the pH was then brought to 7·2 with $N/10$ caustic soda. These fractions were treated in the way described for plasma, except that fibrinogen was added to the albumin solution to a final concentration of 300 mg. per 100 c.cm. The globulin contained the fibrinogen of the original plasma.

Dry streptokinase was prepared by the method of Christensen (1945) by Dr. E. S. Duthie and used in a final concentration of 0·1%. It had no action alone on the fibrin prepared in these experiments, but, as a precaution, after 30 minutes' incubation with the plasma or plasma fraction to be studied, it was inactivated by the addition of a predetermined amount of antiserum also prepared by Dr. Duthie.

EXPERIMENTAL RESULTS

The results of the experiments (*A–R*) are shown in the table, each horizontal row indicating the presence (+) or absence (0) of fibrinolysis at a particular dilution. They are representative of a number of repetitions.

A—Dilutions of normal plasma show no lysis in 24 hours.

B—Incubation of normal plasma with streptokinase before dilution results in lysis in tubes 4 to 9, this last dilution (1 in 1024) representing the titre of the activated plasmin. The surprising absence of lysis in the first three tubes is important. It is probably due to the presence of an inhibitor which loses its effect on dilution.

C—"Chloroform plasma" destroys fibrin to a dilution of 1 in 256 (tube 7), but without any initial inhibition.

D—Streptokinase added to chloroform plasma increases the plasmin titre to 1 in 2048 (tube 10), suggesting that chloroform alone does not activate all the enzyme precursor.

E—Spontaneously active plasma lyses fibrin to tube 6, with inhibition in the first tube.

F—Streptokinase added to "active plasma" extends lysis to tube 8, without inhibition, suggesting that there is a reduction of inhibitor but incomplete activation of the enzyme precursor in "active plasma."

---

* The buffer is made as follows: 1·72 g. glyoxaline and 90 c.cm. of $N/10$ HCl are made up to 100 c.cm. with water; 5 c.cm. of this is added to 245 c.cm. of 0·9% saline containing 0·001% merthiolate.

† A 1/250 dilution in buffer mixture of "clotting globulin" prepared by Lederle Laboratories Inc., New York. This thrombin preparation has no fibrinolytic activity. Preparations of human thrombin have been used but are sometimes spontaneously fibrinolytic.

‡ The methods by which spontaneous fibrinolytic activity can be produced in human subjects will be described in a later publication.

G—Normal globulin is spontaneously active to tube 5, without inhibition in the first tubes.

H—The activity of normal globulin is increased to tube 8 by streptokinase. It contains, therefore, both active enzyme and its precursor.

I and J—Albumin has no activity, even when treated with streptokinase.

K—The spontaneous activity of globulin is lost when it is re-combined with albumin in the normal proportions.

L—The albumin from chloroform plasma has no inhibitory power on normal globulin.

M and N—The globulin fraction from chloroform plasma is more active than normal globulin, but is completely inhibited by normal albumin.

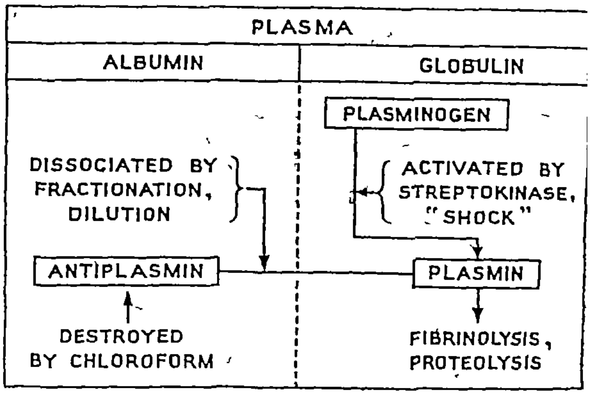
O—The albumin fraction from plasma treated with streptokinase inhibits normal globulin in the first three tubes, but there is lysis in tubes 4 and 5. This may suggest that there is some reduction of the potency of the inhibitor after treatment with streptokinase, *but it is possible that some of the* kinase was carried over with the albumin fraction to activate the globulin.

P and Q—The globulin fraction of spontaneously active plasma is more lytic than normal globulin, but, in this experiment, is completely inhibited by normal albumin. In other experiments, however, with more active globulin, normal albumin may not completely inhibit lysis.

R—The albumin from "active plasma" does not completely inhibit normal globulin.

DISCUSSION AND CONCLUSIONS

From these experiments it appears that normal plasma contains at least three factors concerned in fibrinolysis. In the "globulin fraction" is a certain amount of active plasmin, and a further quantity of its precursor, plasminogen. It might be argued that the activity observed in this fraction was induced by the technique of separation, but, since it is lost on re-combination with albumin, it is reasonable to suppose that this proportion of plasmin exists in normal blood in combination with the antiplasmin of the albumin fraction. If this is so, the combination is a loose one, being broken by fractionation. Moreover, if the plasmin content of plasma is for any reason increased, fibrinolytic activity firs becomes apparent in the higher dilutions of the plasma suggesting that dilution favours dissociation of th plasmin-antiplasmin complex, though in normal plasm there is a sufficient excess of inhibitor to prevent activation. This dissociation explains the results of Macfarlan (1937), who found diluted plasma a more sensitive inde of fibrinolysis than whole blood. A similar effect o dilution has been observed on trypsin-antitrypsin mixtures (Hussey and Northrop 1923) and on toxin-antitoxin mixtures (Glenny and Barr 1932).



PLASMA
ALBUMIN
GLOBULIN
PLASMINOGEN
DISSOCIATED BY FRACTIONATION, DILUTION
ACTIVATED BY STREPTOKINASE, "SHOCK"
ANTIPLASMIN
PLASMIN
DESTROYED BY CHLOROFORM
FIBRINOLYSIS, PROTEOLYSIS

It is alteration of the plasmin-antiplasmin balance, therefore, that determines the presence or absence of fibrinolytic activity in blood. Alterations resulting in an increased activity have been observed as follows:

(1) Streptokinase increases the plasmin content of the plasma by activating available plasminogen, but does not appear greatly to affect the antiplasmin, a conclusion in conformity with that derived by Christensen and MacLeod (1945) by other methods.

(2) Chloroform destroys antiplasmin, thus releasing the plasmin normally in combination with it. It has been previously observed that the antiproteolytic action of serum is destroyed by chloroform (Jobling and Peterson 1914, Dale and Walpole 1916, Teale and Bach 1919).

PRESENCE OR ABSENCE OF FIBRINOLYSIS IN DILUTIONS OF PLASMA OR PLASMA FRACTIONS WITH VARIOUS REAGENTS, AND CONSTANT FIBRINOGEN

uch an action was considered but rejected by Christensen and MacLeod (1945), who did not suppose that plasmin was normally present in the blood.

(3) The spontaneous fibrinolytic activity observed in our subjects is due to an increase in plasmin; and also, apparently, to a decrease in antiplasmin, an observation that requires further confirmation and investigation. The mechanism by which plasminogen is activated in these subjects is at present unknown.

The foregoing conclusions can be illustrated diagrammatically (see figure). Such a scheme, it is realised, is hypothetical, and further work may require fundamental alterations.

Our thanks are due to Dr. E. S. Duthie, of the Lister Institute, Elstree, for much advice and practical help, and to Dr. A. H. T. Robb-Smith for his encouragement and criticism. The general investigation of fibrinolysis is financed by the Medical Research Council.

EXERCISE AND CARDIAC HYPERTROPHY *

Sir ADOLPHE ABRAHAMS
O.B.E., M.D. Camb., F.R.C.P.
PHYSICIAN TO WESTMINSTER HOSPITAL AND TO THE INTERNATIONAL ATHLETIC BOARD; HONORARY MEDICAL OFFICER TO THE BRITISH OLYMPIC ATHLETIC TEAM

PHYSICIANS and physiologists differ in opinion on the subject of cardiac hypertrophy in response to exertion. On the one hand, there is the à priori expectation, the analogy of the musculature of the blacksmith's arm. On the other hand, there is the pronouncement of cardiologists that, provided the cardiac muscle is healthy and there is no valvular disease, hypertrophy does not develop even after the most severe physical exertion of which a human being is capable, whether that exertion be a repetition of occasions of supreme intensity or a long-continued submaximal effort: hypertrophy is regarded as evidence or proof of some pathological condition in the cardiovascular system or in some other system with cardiovascular repercussions. Though the present communication is intended as a criticism which may be at variance with previous experience and admit some vacillation in the retention of a long-established opinion, I have on clinical and radiographical grounds never found occasion to doubt that the healthy heart never hypertrophies, and this belief is founded on very considerable experience of athletes of every variety: of oarsmen; of runners at all distances, from sprinters to Marathon performers; of cyclists engaged in such feats as twenty-four hours' continuous pedalling; and of Channel swimmers.

Analogy with the blacksmith's arm may well be fallacious; cardiac muscle is not the same thing as voluntary skeletal muscle. Moreover, I have always felt that undue emphasis is laid on the function of the heart in considering the capacity for athletic distinction and regarding it as the limiting factor for endurance. Admittedly the work done by the heart in extreme exertion is of a very high order: each ventricle at maximal pressure delivers thirty-four litres of blood a minute. But, though the argument is specious, it seems to me a gratuitous assumption that, granted a peculiarly superlative circulation ensuring an unlimited provision of blood, a corresponding delay or avoidance of fatigue would result. The capacity for physical effort depends on various circumstances. It may well be that the superathlete owes his capability to the quality of his blood; to its viscosity, perhaps, or even to some subtle biochemical factor. It may be that his muscles have exceptional endowments for oxygen utilisation, for tolerance for lactic acid, or for the development of antibodies to ensure its neutralisation. Above all there is the nervous element, not only as a coördinating agent for the most perfect harmonisation of all the factors concerned but also from the psychological aspect.

Comparison with the lower animals is unconvincing. We may measure such details as stroke volume, circulation-rate, vital capacity, and oxygen debt. What are immeasurable and imponderable are such qualities as determination, stoicism, the ability to withstand discomfort and fatigue, or to endure the miseries of heat, cold, hunger, and thirst, and most of all in respect to long-continued exertion, monotony and boredom. The limiting factors of endurance are by no means restricted to the circulation.

AN ILLUSTRATIVE CASE

A man, aged 78, consulted Mr. G. T. Mullally for a swelling of the neck of three months' duration. His previous health had been consistently excellent; his activity until the last few weeks of his life had remained unimpaired. A tumour (probably malignant) of the thyroid gland compressing the œsophagus and invading the right external jugular vein was diagnosed, and deep X-ray therapy was undertaken. Sudden death took place shortly after the start of treatment.

As a necropsy was permitted, I requested particular attention to the heart and blood-vessels. I had not known the deceased in life, but his reputation as an athlete in his youth was of an almost legendary order. In the opinion of authorities he was the greatest long-distance cyclist of any generation. At the age of 18 he broke records for the bicycle and tricycle rides from Land's End to John o'Groats. During eleven years of incessant cycling he created nineteen national records. He had a partiality for the Land's End to John o'Groats achievement, and contemporary members of our profession warned him that every such performance reduced his life expectation by ten years. This effort he accomplished on twenty-four occasions.

After terminating his career as a long-distance cyclist he continued as an outstanding performer at cricket, hockey, swimming, and lawn tennis for the remainder of his life. As a professional soldier he took part in the 1914-18 war (lieut.-colonel and D.S.O.) and in the 1939-45 war with full duties in the Home Guard. I regret that no clinical details—e.g., cardiac rate and blood-pressure—are forthcoming. His height was 5 ft. 11 in., and his weight, which remained substantially unaltered throughout adult life, was just under 11 st. He was a non-smoker and almost a total abstainer from alcohol.

At the necropsy an embolus—the cause of death—was found in the left pulmonary artery.

The lungs were healthy and free from emphysema; there was adherence of the left pleura, with a calcified nodule at the left base. The heart was large, weighing 18 oz., but was "remarkably healthy for a man of his age." The muscle was firm and without fatty changes or infarctions. The coronary vessels were entirely free of atheroma. The aorta was in a remarkable state of health. The valves were normal; the aortic valves appeared larger than normal, measuring 4 cm. × 2 cm.

"The kidneys were quite normal, weight rt. 6 oz., lt. 8 oz. Liver, spleen (weight 4 oz.), and other viscera were quite normal."

DISCUSSION

Here is an example of a man who indulged in the most severe form of violent exercise in his youth for eleven years and in moderately strenuous exertion for the rest of his life; who survived with perfect health to the age of 78 to succumb to malignant growth of the thyroid and a fortuitous pulmonary embolus; at whose death a considerably hypertrophied heart was discovered, with complete absence of any disease in the cardiovascular system and a condition of exceptional healthiness of all viscera for a man of his age.

---

* A communication to the Association of Physicians, April, 1946.

It is generally accepted that species or even breeds of animals distinguished for muscular power have unusually large hearts. The ratio $\frac{\text{heart weight} \times 100}{\text{body-weight}}$ is always greater than 0·6 in those capable of severe continued exercise. The qualification *continued* must be stipulated, since animals with very small hearts are capable of extreme exertion for a short time if no considerable oxygen debt is incurred.

But this is not to presume that hypertrophy of the heart can be induced by severe exercise, and clinical and radiological investigations applied to athletes who indulge in long-distance events have provided little evidence of such effect. Admittedly, these investigations, however skilfully performed, are not conclusive. The only proof is that afforded by necropsy, and appropriate opportunities are exceptionally rare. Necropsies of subjects aged 78 are only too likely to reveal degene tive changes which are the usual consequence of a The factors of inactivity, gluttony, and intemperar all have a bearing; hence the responsibility of physi exertion in earlier life can rarely be incriminated as isolated factor.

I venture to advance two provocative alternativ as a lesson from this example. Either cardiac hyp trophy, analogous to muscular hypertrophy generall *does develop in response to violent exercise*; or sor human beings naturally possess exceptionally large hear and are constitutionally fitted for protracted exertion.

SUMMARY

An example is presented of a phenomenal athlet who died at the age of 78, in whom at necropsy cor siderable hypertrophy of the heart was revealed, bu whose cardiovascular system was in an extremely health state.

The relationship of cardiac hypertrophy to physica exertion is discussed.

I am greatly indebted to Mr. G. T. Mullally for permissio to record this note, and to Prof. R. J. V. Pulvertaft fo his generous coöperation in respect to the necropsy an information relating to the crucial details.

Reviews of Books

Atlas of Surgical Approaches to Bones and Joints

TOUFICK NICOLA, M.D., F.A.C.S., professor of orthopedics, New York Polyclinic. London: Macmillan. Pp. 218. 25*s*.

BY over 200 diagrams and black-and-white drawings, Professor Nicola cleverly and clearly represents the methods of approach to all bones and joints. The chief features are the large scale of the illustrations—almost life size—and the bold delineation of the structures. Here are no detailed anatomical drawings in the da Vinci style, nor loose impressionist effects, but bold, semi-diagrammatic drawings which certainly get their message across. The approaches are those that Nicola has found of value, and as such should be good enough for most of us. The majority are familiar, but some—such as the deltoid-displacing methods for the shoulder-joint—should be used more often. There are definite advantages in exposing the lumbar spinal cord with the patient in the lateral position, as he describes. For the young, this is a simple textbook of the essentials of orthopædic anatomy, for the old a quick reference work for use before a less familiar operation on bone or joint.

Carbohydrate Metabolism

SAMUEL SOSKIN, director of the research institute, Michael Reese Hospital, Chicago; and RACHMIEL LEVINE, director of metabolic and endocrine research at the hospital. London: Cambridge University Press. Pp. 315. 33*s*.

Claude Bernard's genius is emphasised in this book. The authors return again and again to the views of the great pioneer, upon whose work so much of our knowledge of carbohydrate metabolism is based. And in this the authors show their own greatness, for they set out to provide a book to be used for teaching, bringing the subject matter up to date, and presenting it suitably for the scientifically minded physician. Well designed and critically and sympathetically written, the book could only have been put together by men who had themselves thought and worked for many years at the subject. The diagrams and structural formulæ are helpful, and the summary, in the biochemical section, of the enzymatic processes involved in carbohydrate oxidation is very clear. The section criticising the classical criteria of diabetes is interesting, the authors piling up the evidence against the non-utilisation theory in an instructive manner. The rôle of the endocrine glands in carbohydrate metabolism is fully discussed, and with surprising simplicity. Some of the final chapters will appeal most to clinicians. Some aspects of carbohydrate metabolism which have been almost neglecte might with advantage have been included. The reference to, and accounts of, the pentose sugars for instanc are incomplete enough to be misleading, and there i little description of our growing knowledge of the sugar concerned in nucleic acid metabolism; but perhap these subjects hardly came within their terms o reference.

Symptomatic Diagnosis and Treatment of Gynæco logical Disorders

(2nd ed.) MARGARET MOORE WHITE, M.D., F.R.C.S. M.R.C.O.G., surgical specialist, Three Counties Emer gency Hospital. London: H. K. Lewis. Pp. 240 16*s*.

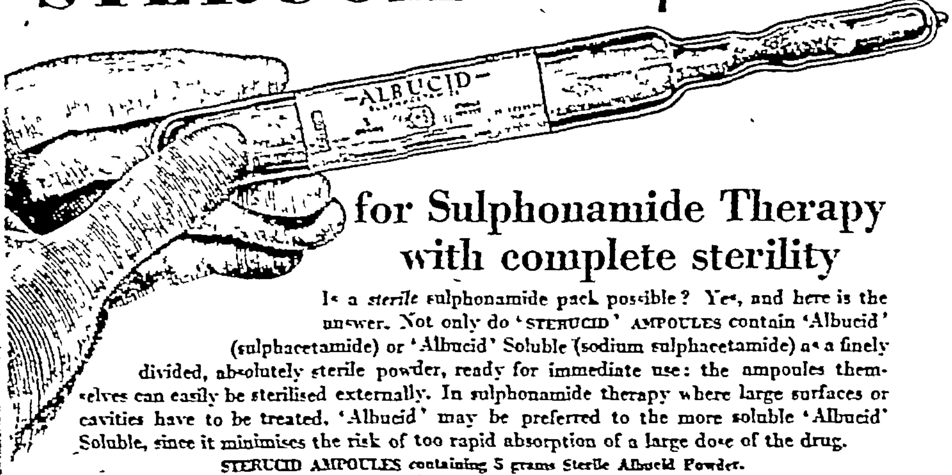
THIS small book, published in the "General Prac titioner" series, covers a wide territory and covers it well. The subject matter is up to date; the diagnosis and treatment are sound, and the illustrations graphic. Miss Moore White counsels expectant treatment in intratubal pregnancy with death of the fœtus, and in abortion of a separated tubal pregnancy. This may be safe for a surgeon of her diagnostic acumen and wide experience, but in writing for general practitioners such advice seems dangerous, since the extra-uterine pregnancy which is likely to bleed and the one which is not may easily be confused, with disastrous results for the patient. The chapter on sterility is among the best in any textbook of gynæcology, and a useful chapter on contraception has been contributed by Dr. Mary Redding. Irradiation therapy is discussed by Mr. I. G. Williams, who adequately covers the needs of general practice.

A Textbook of Surgery

(4th ed.) Editor: FREDERICK CHRISTOPHER, M.D., F.A.C.S., associate professor of surgery, Northwestern Univ sity, Chicago. London: W. B. Saunders. Pp. 1548. 60*s*.

THIS new edition has been revised and reset, and two new sections have been added on chemotherapy and military surgery. New readers may or may not dislike the double-column page; and there is some inevitable unevenness associated with the multiplicity of authors, so that the sections on the operative treatment of trigeminal neuralgia or spina bifida are as long as the whole section on tuberculosis of joints. But these are minor criticisms. The illustrations are everywhere good, particularly those of operative procedures, and the style is generally lucid and fluent. This book has always been among the transatlantic productions which British undergraduates could read with profit and pleasure and they will find it a useful adjunct to our own standard works.

‘STERUCID’ Ampoules

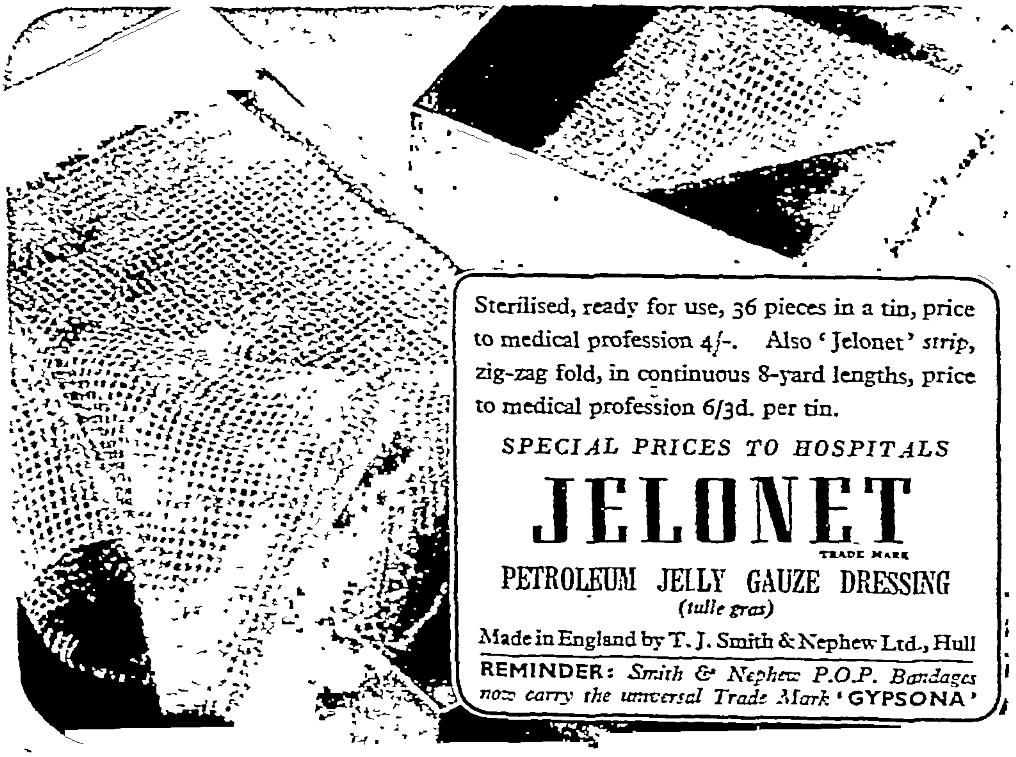


for Sulphonamide Therapy with complete sterility

Is a *sterile* sulphonamide pack possible? Yes, and here is the answer. Not only do ‘STERUCID’ AMPOULES contain ‘Albucid’ (sulphacetamide) or ‘Albucid’ Soluble (sodium sulphacetamide) as a finely divided, absolutely sterile powder, ready for immediate use: the ampoules themselves can easily be sterilised externally. In sulphonamide therapy where large surfaces or cavities have to be treated, ‘Albucid’ may be preferred to the more soluble ‘Albucid’ Soluble, since it minimises the risk of too rapid absorption of a large dose of the drug.

STERUCID AMPOULES containing 5 grams Sterile Albucid Powder.
STERUCID AMPOULES containing 5 grams Sterile Albucid Soluble Powder.
Fully descriptive literature will be sent on request.

BRITISH SCHERING LIMITED BS 167 169 Great Portland St., London, W.1



Sterilised, ready for use, 36 pieces in a tin, price to medical profession 4/-. Also ‘Jelonet’ *strip*, zig-zag fold, in continuous 8-yard lengths, price to medical profession 6/3d. per tin.

THE LANCET

LONDON: SATURDAY, OCT. 19, 1946

The Curtain

It is a great misfortune that so many doctors should dissociated from the Government's effort to create comprehensive medical service. Now that many of e desires and aspirations of the profession stand a hance of fulfilment, a substantial proportion of its embers seem to be chiefly concerned with the inconeniences and risks that are inseparable from any major change These inconveniences and risks are ery far from negligible, but they should not obscure he larger view presented once again in the Lords' ebate last week. In that debate one of our spokesmen ad to admit that in approaching the Bill "too many of the doctors have merely expressed their fears and prejudices" and "it has been left to the Minister to generate the momentum that overcomes obstacles and to enlist the strenuous support of ardent minds" The House of Lords at least showed itself aware of the significance of the project now being undertaken: "I am quite convinced," said the Archbishop of YORK, "that the National Insurance Act . . . and this Bill . . . will prove by far the greatest social reforms which have ever been passed by Parliament." Its evolutionary, rather than revolutionary, character was emphasised by Lord LISTOWEL: there has been, he pointed out, a deplorable hiatus between the progress of medicine and its social application, and "as a citizen of a country which still cares about social justice and the intangibles that really matter" he welcomed a measure which "by its inclusiveness, by its more even distribution of the nation's medical resources, and most of all by breaking the cash nexus between medicine and the individual, will remove the gravest of the present obstacles to one of the most important forms of equality of opportunity." Lord BEVERIDGE approved of the Bill as giving effect to the vital principle that bread and health for everybody should come before cake and circuses for some. It sets up for the first time, he said, a true Ministry of Health ("a national authority with the duty and with the power of attacking disease as a national enemy") and it means that the medical profession will now be a service rather than in any way a business.

So much for intentions. But, as Lord ADDINGTON remarked, under the new régime "the love, care, and consideration which are so essential to healing cannot be exercised if there is friction between the doctors and the Government or between the doctors and the patients"; and the LORD CHANCELLOR agreed that it would be very foolish to construct the scheme on the basis of a disgruntled and dissatisfied profession. Unhappily that is just what a great many doctors are today—distinctly disgruntled. And perhaps the main reason for their state of mind is that they suppose that the Minister of Health, receiving plenary powers from a political majority, is not paying, and need never pay, any attention at all to the views of their representatives. People who have closely followed the development of the plan for a comprehensive medical service know that, as Lord LISTOWEL argued, it is the outcome of a concerted effort, over a long period of years, in which every view of any importance has been given a fair hearing and prolonged and serious consideration. Nevertheless Mr. BEVAN's treatment of the Negotiating Committee has made it just possible for opponents to assert that the scheme in its final form was thrust on the profession "without consultation." Though he listened repeatedly to the committee's views, expressed both collectively and individually, he believed, rightly or wrongly, that the shaping of the main policy was a matter for himself and Parliament, not to be prejudiced by bargaining in advance. Thus, though there were consultations, it is true that there were, strictly speaking, no negotiations.

Mr. BEVAN evidently looks forward to detailed discussions later; which indeed will be essential. Meanwhile, however, the failure to achieve more genuine coöperation—a failure for which both parties bear some responsibility—has proved singularly unfortunate. Its most conspicuous result at the moment is the trouble over the National Health Insurance capitation fee. The Minister, while recognising that in the light of the Spens report the remuneration of panel practitioners must be increased, was naturally unwilling to discuss this subject except in its relation to remuneration in the National Health Service which will supersede National Health Insurance in eighteen months' time. The Insurance Acts Committee, on the other hand, demanding immediate action on the Spens Committee's findings, declined to discuss remuneration in some hypothetical service which may or may not materialise in 1948. On their refusal, the Minister increased the capitation fee by 2s. as a token payment without prejudice—an action which has apparently led countless practitioners to think that such matters will never be decided on their merits, and that, even in a National Health Service, the Ministry will never change its spots. We are thankful to hear of the Minister's new approach; for though both sides have a good case, there is really less need of good cases than of good will.

But mere appeasement between two separate parties—the Ministry and the profession—is not of course enough: we have to construct an organisation whose different parts work harmoniously to a common end. This has to be done, moreover, without dictatorship. Much of the anxiety of the profession arises, as Lord HORDER said, from the centralisation of power in one man, who was compared by several speakers to the commander-in-chief of an army. Lord LISTOWEL gave an assurance that the Minister's duty will be to exercise direction rather than control; and Mr. BEVAN has recognised that every professional member of the new service must remain responsible for his own work. The Archbishop of YORK did well, however, to point out that the staff of the commander-in-chief "will consist largely of those who live and work in Whitehall, and probably the majority of them will be people who have never practised within this profession and fail to understand its spirit" Though the scheme provides mechanisms through which the profession at all stages can profoundly influence the development and administration of the service, "the Minister"—which usually means "the Ministry"—could no doubt by bureaucratic action do much to defeat the object of those who have designed these mechanisms. Against this the best safeguard is that the Minister's staff should include many men who are for part of their

navigation, needlework, or darts. The chief feature that the homes have in common is that patients go there after an illness expecting to get better without further active treatment. Almshouses may therefore be excluded from the definition—whatever that is finally decided to be—and classed among provisions for the old; for no-one expects to get better of old age. And so may the active reablement centres which have developed in the last few years, for in these the patients are as much under treatment as they were in hospital, though at a later stage of recovery.

English convalescent homes range in size from those taking more than 200 to those taking less than 20 people; and though those who are planning our National Health Service are said to prefer large units there is little doubt that patients prefer small homes of 10 to 20 beds, especially when these are run with friendly personal touch. The existing homes vary n this, of course, as in everything else: in one home he children make a friendly rush at the chairman the moment he appears, and the matron speaks of the patients by name; in another the efficient filing system s the keynote of the institution, and the patients are called cases. There is the story of the old lady in a large, clean, airy, perfectly run home in Prague who said with a sigh, "There's nothing left but tidiness." The English may respect institutions but are peculiarly ill-fitted for living in them. The main argument in favour of large hospitals—that only they can afford the special equipment and personnel required for modern diagnosis and treatment—does not apply to the general run of homes for convalescents, who need neither apparatus nor highly skilled care. It does, however, apply to the reablement centres which aim, by active and often complex and expensive methods, to get working men and women back to their jobs. In the no-treatment home large size is a handicap, for it necessitates a medical and nursing staff, whereas the small home can rely on local practitioners to attend to minor ailments and keep an eye open for unexpected complications. The small home where the matron and committee know the patients personally, and where freedom is respected, cups of tea can be had without formality, and no-one is sent packing because he drinks a glass of beer in the local inn, is clearly the right kind for English convalescents.

Variety and small size, then, are qualities in convalescent homes which we should strive to keep. Their weakness lies in their having no connecting link, no central body to which inquiries can be addressed by almoners and others trying to place a patient, or to which the homes themselves can look for advice or help in moments of difficulty. Some degree of central supervision would clearly improve the service that the homes can offer: and most homes would welcome it as relieving them of the responsibility inherent in isolation. A central organisation would simplify the task of almoners: for though there is probably a suitable type of home for anyone who needs it, there is not always a bed waiting for a particular patient at a particular moment; or, if there is, the almoner has no means of knowing it. The central organisation could set up a simple form of admission bureau, on the lines of the bed service run by the King's Fund in London for emergency admissions to hospitals. As a first step the King's Fund and the Institute of Almoners are preparing a detailed list of homes, based on personal inspection. This will meet a real need, and will also show which groups of people are poorly served by the homes already existing, and possibly which have more opportunities for convalescence than they require.

Annotations

WINTER IN EUROPE

IN Europe this winter, and particularly in the occupied zones, hardship is likely to be extreme. The Control Commission recently announced that during the last week of July, in the British zone of Germany, 12 people died of hunger, while 1189 cases of famine œdema were reported in Hamburg alone. During six months the new-case rate of tuberculosis, it was stated, rose by a third. In a pamphlet lately issued,[1] Viennese rations for a day during the past summer are described by Mr. G. E. R. Gedye.[2] They were two rounds of bread (under 9 oz.), a teaspoonful of sugar, a tablespoonful of coffee and coffee substitute, half a square inch of sausage and an equal amount of tinned ham, a tablespoonful each of maize flour, dried peas, oatmeal, and lard, a seventh share in a shell egg, a pinch of egg powder, half a soup cube, a dessertspoonful of salt, and two tablespoonfuls of meat-and-vegetable ration (three-quarters vegetable): the total calorie value being estimated at 1181—about half the figure (2200) regarded as adequate for a non-worker. These embittering privations can only be ended by good harvests and political decisions; but in the meantime there is room and to spare for voluntary effort.

Since 1945 British voluntary societies have been doing welfare work in the British zone of Germany.[3] They are grouped in teams of 12 and represent the British Red Cross and Order of St. John, the Friends Relief Service and Friends Ambulance Unit, the Salvation Army, the Girl Guides, the Save the Children Fund, the Catholic Committee for Relief Abroad, and the International Voluntary Service for Peace. Many of these bodies, of course, are sending help to other distressed countries—to France, Poland, Austria, Italy, Yugoslavia, and Greece. The relief workers in Germany receive their rations, petrol, and other stores through the Army, and use Army vehicles; but they are not paid or regulated by the Army and many of them receive no pay at all. They began by caring for refugees and victims of epidemics and starvation in Normandy, Belgium, Holland, and Rhineland, while the fighting was still going on; later they helped to repatriate displaced persons of Allied nationality in Germany. Later still some of them became free to give help to the German population, and additional teams arrived from England to supplement them. Supplies of course are limited, and are used primarily for children, sick people, and the aged. Wherever possible German organisations which understand local needs are asked to help with distribution.

In towns with a population over 5000 the education branch of Control Commission has arranged for schoolchildren to receive a coupon-free midday meal; and supplementary feeding schemes for children under school age have been arranged by the relief teams. The Swedish Red Cross and the Swiss relief organisation known as Don Suisse are helping with this work. Swedish teams in the Ruhr have provided a daily hot meal for 120,000 children in the past six months, and Don Suisse time actually engaged in the practice of medicine. "It is only in this way," said Lord MORAN, "that you can lift the curtain which in recent years has fallen between the Ministry and the profession, leaving so much want of sympathy and understanding." And in this he was endorsing the far-seeing policy by which Sir WILSON JAMESON has been widening the medical staff of the Ministry and intends to widen it further.[1]

The new service will succeed if those who hold office in it, whether medical or lay, prove themselves colleagues and are trusted accordingly. The immediate necessity, however, is effective consultation over the framing of the regulations which will bring the service to life. In these consultations our representatives can certainly wield their proper influence, and they can also prove their readiness for real coöperation. The Government, as Lord ADDINGTON said, has yet to win the confidence of the medical profession and the public; but the profession might itself do more to gain the confidence of its associates in a great, and now inevitable, undertaking.

Circulatory Effects of Osteitis Deformans

WHEN Sir JAMES PAGET[1] described the generalised disease of bone now known by his name he recognised that the bones were hyperæmic, and this led him to think of an inflammatory cause and hence to use the term "osteitis." Orthopædic and cranial surgeons are familiar with the highly vascular state of the affected bones at operation, and CONE,[2] in his studies of the bone pathology, emphasised the importance of this feature. KLIPPEL and WEIL[3] in 1908 observed that the temperature of the skin over an affected bone was higher than normal. For a long time cardiovascular complications of the generalised form of Paget's disease have been recognised. KAY and others[4] were struck by the frequency of high pulse-pressures in a series which they studied. Out of 33 cases, 14 had pulse-pressures over 60 mm. Hg. Cardiac enlargement was often noted, as were systolic murmurs over the precordium. Even in cases in whom the Korotkoff sounds could be heard right down to zero pressure, there was no satisfactory evidence of aortic valvular disease. KAY and his colleagues and also SNAPPER[5] ascribed these findings to arteriosclerosis.

Further light has now been thrown on these phenomena by a detailed study[6] of a case in the British Postgraduate Medical School. A patient with generalised Paget's disease had venous congestion and œdema. Cardiac catheterisation showed that his cardiac output was 13·3 litres per minute, or nearly three times the normal average. This is a state of affairs somewhat similar to that found in arteriovenous aneurysms, and in fact closing the circulation through the legs of this patient produced effects on the general circulation similar to those seen when an arteriovenous aneurysm is partially shut off, including slowing of the pulse and a slight rise in diastolic arterial pressure. This led the investigators to believe that the circulatory phenomena might be explained by a great increase in blood-flow through the affected bones. Direct study of the bone blood-flow was then undertaken. It was shown that when one tibia only is affected by Paget's disease the flow through that leg may be five to seven times as high as that in the normal leg. By an ingenious adaptation of the Grant-Lewis plethysmograph the actual bone blood-flow was estimated in the humerus of a normal person and the patient with Paget's disease. It was found that the normal flow was probably about 1 c.cm. per 100 c.cm. of bone per minute, while that through Paget's bones was about 20 c.cm. Applying these figures to the whole skeleton, the total skeletal blood-flow is normally about 75 c.cm. per minute, while the enlarged skeleton of the case of generalised Paget's disease received a blood-flow of about 3·3 litres per minute.

This work is an important contribution to the living pathology of Paget's disease, but it is also the first time that bone blood-flow has been measured in man. It adds another thought-provoking instance to the group of conditions in which "cardiac failure" is associated with high output, of which severe anæmia constitutes a well-established example.[7] Comprehension of the nature and sequence of events in these cases of apparent heart-failure would shed much light on other ordinary forms of heart-failure, and we may look forward to further results of such research in the next few years.

The Convalescent Home

"LET not thy left hand know what thy right hand doeth," however apt as advice on personal almsgiving, is hardly a suitable maxim for charitable institutions. Yet convalescent homes in England have grown up on this isolationist plan, each pursuing a course of its own, knowing nothing of its neighbour in the next street. No complete list of convalescent homes has ever been compiled; even the Public Health Act of 1936 did not call for a complete survey; and hospital almoners, local health officers, and practitioners must make their own lists of openings available for their patients recovering from illness. Many homes were closed during the war and not all have opened again. Moreover, there is no clear definition of the term "convalescent home." Some offer treatment, others none; some will not take patients for more than a month, others will not take them for less; some insist that patients must be able to look after themselves, others will take the bed-ridden; some of the children's homes are special schools approved by the Ministry of Education, others are not. At many, patients must conform to certain criteria—they must be of a given sex or age-group, or must belong to a given religious sect, fraternity, friendly society, or social class, or must work at or be retired from a given occupation, including the Services, or must live in a given district. The variety of our convalescent homes is an advantage, for the restrictions on the type of patient are designed to make those who are accepted feel more at home, the first essential for pleasant convalescence. A merchant seaman, a distressed gentlewoman, and a resident of West Ham, placed in one home, might be poor company for each other, but they will be at ease among those who share their tastes, whether in

navigation, needlework, or darts. The chief feature that the homes have in common is that patients go there after an illness expecting to get better without further active treatment. Almshouses may therefore be excluded from the definition—whatever that is finally decided to be—and classed among provisions for the old; for no-one expects to get better of old age. And so may the active reablement centres which have developed in the last few years, for in these the patients are as much under treatment as they were in hospital, though at a later stage of recovery.

English convalescent homes range in size from those taking more than 200 to those taking less than 20 people; and though those who are planning our National Health Service are said to prefer large units there is little doubt that patients prefer small homes of 10 to 20 beds, especially when these are run with a friendly personal touch. The existing homes vary in this, of course, as in everything else: in one home the children make a friendly rush at the chairman the moment he appears, and the matron speaks of the patients by name; in another the efficient filing system is the keynote of the institution, and the patients are called cases. There is the story of the old lady in a large, clean, airy, perfectly run home in Prague who said with a sigh, "There's nothing left but tidiness." The English may respect institutions but are peculiarly ill-fitted for living in them. The main argument in favour of large hospitals—that only they can afford the special equipment and personnel required for modern diagnosis and treatment—does not apply to the general run of homes for convalescents, who need neither apparatus nor highly skilled care. It does, however, apply to the reablement centres which aim, by active and often complex and expensive methods, to get working men and women back to their jobs. In the no-treatment home large size is a handicap, for it necessitates a medical and nursing staff, whereas the small home can rely on local practitioners to attend to minor ailments and keep an eye open for unexpected complications. The small home where the matron and committee know the patients personally, and where freedom is respected, cups of tea can be had without formality, and no-one is sent packing because he drinks a glass of beer in the local inn, is clearly the right kind for English convalescents.

Variety and small size, then, are qualities in convalescent homes which we should strive to keep. Their weakness lies in their having no connecting link, no central body to which inquiries can be addressed by almoners and others trying to place a patient, or to which the homes themselves can look for advice or help in moments of difficulty. Some degree of central supervision would clearly improve the service that the homes can offer: and most homes would welcome it as relieving them of the responsibility inherent in isolation. A central organisation would simplify the task of almoners: for though there is probably a suitable type of home for anyone who needs it, there is not always a bed waiting for a particular patient at a particular moment; or, if there is, the almoner has no means of knowing it. The central organisation could set up a simple form of admission bureau, on the lines of the bed service run by the King's Fund in London for emergency admissions to hospitals. As a first step the King's Fund and the Institute of Almoners are preparing a detailed list of homes, based on personal inspection. This will meet a real need, and will also show which groups of people are poorly served by the homes already existing, and possibly which have more opportunities for convalescence than they require.

WINTER IN EUROPE

IN Europe this winter, and particularly in the occupied zones, hardship is likely to be extreme. The Control Commission recently announced that during the last week of July, in the British zone of Germany, 12 people died of hunger, while 1180 cases of famine œdema were reported in Hamburg alone. During six months the new-case rate of tuberculosis, it was stated, rose by a third. In a pamphlet lately issued,[1] Viennese rations for a day during the past summer are described by Mr. G. E. R. Gedye.[2] They were two rounds of bread (under 9 oz.), a teaspoonful of sugar, a tablespoonful of coffee and coffee substitute, half a square inch of sausage and an equal amount of tinned ham, a tablespoonful each of maize flour, dried peas, oatmeal, and lard, a seventh share in a shell egg, a pinch of egg powder, half a soup cube, a dessertspoonful of salt, and two tablespoonfuls of meat-and-vegetable ration (three-quarters vegetable): the total calorie value being estimated at 1181—about half the figure (2200) regarded as adequate for a non-worker. These embittering privations can only be ended by good harvests and political decisions; but in the meantime there is room and to spare for voluntary effort.

Since 1945 British voluntary societies have been doing welfare work in the British zone of Germany.[3] They are grouped in teams of 12 and represent the British Red Cross and Order of St. John, the Friends Relief Service and Friends Ambulance Unit, the Salvation Army, the Girl Guides, the Save the Children Fund, the Catholic Committee for Relief Abroad, and the International Voluntary Service for Peace. Many of these bodies, of course, are sending help to other distressed countries—to France, Poland, Austria, Italy, Yugoslavia, and Greece. The relief workers in Germany receive their rations, petrol, and other stores through the Army, and use Army vehicles; but they are not paid or regulated by the Army and many of them receive no pay at all. They began by caring for refugees and victims of epidemics and starvation in Normandy, Belgium, Holland, and Rhineland, while the fighting was still going on; later they helped to repatriate displaced persons of Allied nationality in Germany. Later still some of them became free to give help to the German population, and additional teams arrived from England to supplement them. Supplies of course are limited, and are used primarily for children, sick people, and the aged. Wherever possible German organisations which understand local needs are asked to help with distribution.

In towns with a population over 5000 the education branch of Control Commission has arranged for school-children to receive a coupon-free midday meal; and supplementary feeding schemes for children under school age have been arranged by the relief teams. The Swedish Red Cross and the Swiss relief organisation known as Don Suisse are helping with this work. Swedish teams in the Ruhr have provided a daily hot meal for 120,000 children in the past six months, and Don Suisse time actually engaged in the practice of medicine. "It is only in this way," said Lord **Moran**, "that you can lift the curtain which in recent years has fallen between the Ministry and the profession, leaving so much want of sympathy and understanding." And in this he was endorsing the far-seeing policy by which Sir **Wilson Jameson** has been widening the medical staff of the Ministry and intends to widen it further.[1]

The new service will succeed if those who hold office in it, whether medical or lay, prove themselves colleagues and are trusted accordingly. The immediate necessity, however, is effective consultation over the framing of the regulations which will bring the service to life. In these consultations our representatives can certainly wield their proper influence, and they can also prove their readiness for real coöperation. The Government, as Lord **Addington** said, has yet to win the confidence of the medical profession and the public; but the profession might itself do more to gain the confidence of its associates in a great, and now inevitable, undertaking.

Circulatory Effects of Osteitis Deformans

When Sir **James Paget**[1] described the generalised disease of bone now known by his name he recognised that the bones were hyperæmic, and this led him to think of an inflammatory cause and hence to use the term "osteitis." Orthopædic and cranial surgeons are familiar with the highly vascular state of the affected bones at operation, and **Cone**,[2] in his studies of the bone pathology, emphasised the importance of this feature. **Klippel** and **Weil**[3] in 1908 observed that the temperature of the skin over an affected bone was higher than normal For a long time cardiovascular complications of the generalised form of Paget's disease have been recognised. **Kay** and others[4] were struck by the frequency of high pulse-pressures in a series which they studied. Out of 33 cases, 14 had pulse-pressures over 60 mm. Hg. Cardiac enlargement was often noted, as were systolic murmurs over the precordium. Even in cases in whom the Korotkoff sounds could be heard right down to zero pressure, there was no satisfactory evidence of aortic valvular disease. **Kay** and his colleagues and also **Snapper**[5] ascribed these findings to arteriosclerosis.

Further light has now been thrown on these phenomena by a detailed study[6] of a case in the British Postgraduate Medical School. A patient with generalised Paget's disease had venous congestion and œdema. Cardiac catheterisation showed that his cardiac output was 13·3 litres per minute, or nearly three times the normal average. This is a state of affairs somewhat similar to that found in arteriovenous aneurysms, and in fact closing the circulation through the legs of this patient produced effects on the general circulation similar to those seen when an arteriovenous aneurysm is partially shut off, including slowing of the pulse and a slight rise in diastolic arterial pressure. This led the investigators to believe that the circulatory phenomena might be explained by a great increase in blood-flow through the affected bones Direct study of the bone blood-flow was then undertaken. It was shown that when one tibia only is affected by Paget's disease the flow through that leg may be five to seven times as high as that in the normal leg. By an ingenious adaptation of the Grant-Lewis plethysmograph the actual bone blood-flow was estimated in the humerus of a normal person and the patient with Paget's disease. It was found that the normal flow was probably about 1 c.cm. per 100 c.cm. of bone per minute, while that through Paget's bones was about 20 c.cm. Applying these figures to the whole skeleton, the total skeletal blood-flow is normally about 75 c.cm. per minute, while the enlarged skeleton of the case of generalised Paget's disease received a blood-flow of about 3·3 litres per minute.

This work is an important contribution to the living pathology of Paget's disease, but it is also the first time that bone blood-flow has been measured in man. It adds another thought-provoking instance to the group of conditions in which "cardiac failure" is associated with high output, of which severe anæmia constitutes a well-established example.[7] Comprehension of the nature and sequence of events in these cases of apparent heart-failure would shed much light on other ordinary forms of heart-failure, and we may look forward to further results of such research in the next few years.

are feeding 30,000 children daily in eight towns of North Rhine and Westphalia. Holiday camps have been established for children and young people, and many thousands had a week in the open country or by the sea this summer.

Refugees streaming through the British zone from the east are adding to the heavy burden on the local administration of towns and villages. British and German voluntary societies, working side by side, help with billeting arrangements and personal difficulties, and arrange social and occupational activities for the young people.

Only about 500 British voluntary workers are engaged in these many tasks, a tiny force considering the enormous population needing help. The Council of British Societies for Relief Abroad (COBSRA), however, believe that though they can bring little physical help to those in distress their presence is a token of good will and an example of personal service which will help to restore morale. The COBSRA relief fund has raised £100,000; but the Friends Relief Service, operating not only in Germany but in France, Greece, Poland, and Austria, could use more than that in buying food, medical supplies, clothing, and blankets, over and above the £125,000 required for its regular work in the coming year. The Aid to Austria Appeal Committee needs £20,000 for food, and the Œcumenical Commission for Refugees, under the World Council of Churches, needs £10,000 for the purchase of drugs and medical supplies for Austria and Germany. The Save Europe Now Fund —sponsored by the Bishop of Chichester, Mr. Victor Gollancz (whose pamphlets have done much to make the misery in Europe generally known), Lord Lindsay of Birker, Prof. Gilbert Murray, and the Rev. Henry Carter—is appealing for £150,000 on behalf of these three bodies. The sponsors point out that supplies can be bought immediately, day by day as the money becomes available, so they appeal not only for maximum contributions but for a quick response: a little extra haste in responding may save lives which will otherwise be lost. Cheques should be made out to "Save Europe Now (European Relief Fund)" and sent to 14, Henrietta Street, Covent Garden, London, W.C.2.

FŒTAL RESPIRATION

WHETHER amniotic fluid is inhaled by the fœtus in utero is a controversial question which has been discussed at some length by Windle,[1] who investigated it experimentally in guineapigs. There are two main points at issue—whether the fœtus makes any spontaneous respiratory movements at all, and, if it does, whether these cause the entry of amniotic fluid into the lungs. From general inquiries into fœtal movements there seems no doubt that respiratory movements do occur from time to time in utero, but probably not continuously unless there is some special stimulus. The obvious stimulus is anoxæmia from embarrassment of the placental circulation, and when this is experimentally induced—as by constricting the umbilical cord—most mammalian fœtuses above a certain age respond by respiratory efforts. In investigating the onset and progress of organised movement in the sheep fœtus, Barcroft[2] employed tactile stimuli, the maternal uterus having been opened in a warm bath. The muscular response of the fœtus became more and more brisk and generalised between the 35th and the 50th days of pregnancy, but during the next 10 days inhibition from the higher centres appeared to gain ascendancy, the response becoming less general and the fœtus quiescent. In the phase of rising excitability, the response was more sustained and was rhythmic, being dominated apparently by the respiratory centre. The capacity for respiratory movements, therefore, develops early, but the response to asphyxia does not appear until inhibitory control of the musculature has set in; by this time the likelihood of spontaneous respiratory movements has greatly diminished. Owing to the difficulties of observing the fœtus, demonstrations of the inhalation of amniotic fluid have hitherto not been convincing.

Lately Davis and Potter[3] have introduced thorotrast into the amniotic cavity of human subjects. In twelve therapeutic abortions in which thorotrast was injected 17–48 hours before operation they found that the medium was invariably present in the lungs, while in four where it was administered only $^1/_2$–1 hour before operation it was absent. The X-ray findings were confirmed histologically. The significance of this experiment is increased by the observation that thorotrast failed, or almost failed, to penetrate the alimentary tract of the four control fœtuses, but penetrated that of all the others. In ten babies delivered by cæsarean section, thorotrast placed in the amniotic fluid 16–48 hours previously was definitely present in the lungs of half, and doubtfully present in the remainder. Although the control experiments included the three smallest fœtuses of the series, the results certainly suggest that aspiration of amniotic fluid may normally take place; but the extent and frequency are uncertain, and its physiological significance remains doubtful.

AN AMERICAN VIEW OF RHEUMATISM

ADDRESSING the Empire Rheumatism Council in London on Oct. 11, Dr. Loring T. Swaim (Boston), former president of the American Rheumatism Association, said that extensive surveys in the United States had shown that more than 1 in 6 of the population had some chronic disease. The commonest disorders were rheumatism, heart disease, arteriosclerosis and high blood-pressure, and asthma; and the most potent causes of disability, reckoned by lost work-days, were nervous and mental disorders, rheumatism, and heart disease.

Much has been done to improve the treatment of rheumatism by better teaching and by the activities of the American Rheumatism Association. In 1942 this association, in conjunction with the American Medical Association, produced a primer in which the rheumatic disorders were classified as (1) the frankly infectious, (2) the probably infectious (such as rheumatic fever and Still's disease), (3) degenerative joint disease (osteoarthritis), (4) arthritis due to physical trauma, and (5) disorders associated with disturbed metabolism (gout). The first aim, in Dr. Swaim's opinion, must be to improve general health. The patient should have at least six weeks' complete rest, if possible in hospital, where he is removed from the environment in which he has become ill and can be rested in splints under the care of physician and orthopædist. It is important that the general nutrition should be maintained, with special regard to vitamin deficiency. Small repeated transfusions may help the debilitated, and benefit may be derived from heat and sunlight, and the conservative removal of infective foci. The prevention of deformities is of paramount importance; the deformities of rheumatoid arthritis can, he held, mostly be prevented. Gold therapy, to which the American approach has hitherto been cautious, is now being more widely tried, but not in doses exceeding 50 mg. For Marie-Strümpell disease irradiation and the control of deformities has proved the most reliable treatment.

Dr. Swaim emphasised the importance of psychic factors, and particularly unsettled circumstances at home or at work. In his experience 70% of the onsets and exacerbations of rheumatoid arthritis are traceable to emotional disturbance, of which bad home relations are the commonest cause. Doctors must, he suggested, abandon their preoccupation with the treatment of disease, fascinating as this may be, and, to prevent chronic disease, take a closer interest in the way people live.

CONTROL OF ICE-CREAM

MOST ice-cream manufacturers, and certainly those in a big way of business, are eager to satisfy the public-health authorities; and the neglect by others to ensure reasonable purity may often be due to ignorance of elementary hygiene rather than to carelessness of the consumer's fate. Be that as it may, much of the ice-cream sold today is potentially dangerous to the consumer, who is protected by no general sanctions empowering authorities to inspect ingredients and to supervise manufacture, packing, and storage.

Last week the Ministry of Health published new draft regulations for the heat treatment of ice-cream, which go some way towards filling this deficiency. Where a "complete cold-mix powder" is used, with which only water and colouring or flavouring agents have to be added, the powder is taken to be sterile from the heating it received in manufacture, and no further sterilisation is required, but the powder must be converted into ice-cream within an hour of reconstitution. Other mixtures must be heated to 150° F for 30 minutes, or 160° F for 10 minutes; within 1½ hours the temperature must be reduced below 45° F, and it must be kept so until frozen. If, after freezing, the temperature of any mixture should rise above 28° F it must be submitted or resubmitted to heat treatment.

This announcement drew a brisk rejoinder from the Ice Cream Alliance, which, according to the *News Chronicle*,[1] objects that, owing to the difficulty of obtaining suitable machinery, the regulations cannot be met by next May, when they are to come into operation. At a meeting of the Royal Sanitary Institute the view was that the regulations in themselves are admirable, and will eliminate the maker whose factory is the back bedroom and whose showroom is the street. But they do not go far enough. Plant for heat treatment should be fitted with an automatic recording thermometer, which alone can tell the visiting sanitary inspector whether the regulations are being followed. It should, moreover, not be too much to ask that all ice-cream be sold in closed cartons or wrappers. The regulations do nothing to dispose of the carrier, who may infect a mixture made from sterile powder which, under the regulations, is not resterilised. Tragedies such as that at Aberystwyth this summer will recur until there is some control of the personnel engaged in the handling of ice-cream. This can be attained only by rousing the social conscience with or without the support of the law.

ANTI-MIDGE CAMPAIGN

LAST year a subcommittee of eminent entomologists, under the chairmanship of Prof. F. A. E. Crew, F.R.S., set out to find the best way of using dimethyl phthalate (D.M.P.) to ward off the attacks of Scottish midges which were causing serious irritation among tourists and even the Scottish people themselves. An interim report[2] has now been published. Various ointments containing water were discarded as unsuitable owing to a tendency for the D.M.P. or the water, or both, to creep out. A good paste, however, was made (D.M.P. 15 g., kaolin 10 g., zinc oxide 1 g., soft paraffin 5 g.) which could be put up in collapsible tubes and carried in the pocket. But the most suitable preparation proved to be an emulsion (D.M.P. 100 c.cm., water 100 c.cm., 'Lanette wax' 5 g., triethanolamine 9 c.cm., oleic acid 27 c.cm.), which remained reasonably stable for several months. Preparations based on these formulæ have been on sale during the midge season just ended (July-September). Patch tests were performed, mainly on women forestry workers, and in most cases the application of D.M.P. to the skin caused only a slight tingling or burning for a minute or so, which passed off but returned, perhaps a couple of hours later, on washing the face. During washing, care must be taken that no D.M.P. gets into the eyes, and D.M.P. should not be applied to sunburns or soon after shaving; otherwise no adverse effects on the skin were observed. Field tests were made, with controls who did not use the repellent, and were eminently successful with the paste and emulsion already described, one application to exposed parts warding off attack for at least two hours. Preparations with only 35–40% of D.M.P. were not really effective, because the midges were not repelled but merely paralysed after landing and caused annoyance by crawling about on the skin. Experiments also proved that veils impregnated with D.M.P. were completely successful, whereas unimpregnated veils gave no protection.

The opportunity was taken of making a survey of Scottish midges, about which very little has been known hitherto. Fifteen species of culicoides were collected, of which three had not previously been recorded in Scotland. *C. impunctatus* constituted 76% of the midge population of the west of Scotland and was there responsible for 90% of over 800 bites. In nearly all the collections of *C. impunctatus* and of *C. obsoletus* the sex ratio was "very abnormal." For instance, Glasgow records gave only 4% males, and Dundee only 1%. But in a few collections of *C. impunctatus* the sexes were about equal in numbers. The significance of this fact is said to be obscure. In view of the probability that "the female of the species is more deadly than the male," in that she alone bites, the discrepancy may arise from the different methods of collectors, some collecting only from their attackers, others sweeping with nets the natural habitats of the midges.

CÆSAREAN SECTION

IF there is one operation for which by now the indications should be clear and the technique standardised, it must surely be cæsarean section. Yet anyone who cares to compare the figures in different maternity-hospital reports will find that this happy state has not been reached. Cæsarean section can be regarded in two lights according to temperament. The Tory performs the operation only when the indications are so clear as to leave him little choice. The Radical does the bulk of his obstetrical practice by the abdominal route; to him a cæsarean section is the master key to any obstetrical problem, real or imagined.

From the experience of three firms of surgeons over 14 years Waters[1] has tried to assess the indications for the operation. In 75,238 deliveries, cæsarean section was performed 2039 times. Waters objects to the term "elective cæsarean section," and asks who elects and on what foundation. There is, of course, no dispute about the need for the operation in the presence of obvious fœtal-pelvic disproportion, but only a small minority of cases of so-called disproportion fall into this class. Waters frankly admits that in borderline cases he cannot assess the potential capacity for moulding of the fœtal head, the extent of relaxation of the pelvic joints, and the power and efficiency of the uterine contractions. These are imponderables about which no clinician, however experienced, can prognosticate; and patients in the borderline group should be given a short test of labour, when it will be found that very few need a section. Waters finds that of the last 223 cardiac patients only 4·4% were submitted to section; the decision to operate was determined, even with decompensation, solely by strictly coincidental obstetric indications. Among the group loosely classified as antepartum hæmorrhage not due to placenta prævia, Waters maintains that cæsarean section has little place in mild cases but is important in the severe cases; by severe cases he implies extensive hæmorrhage with an undilated cervix and disruption of the myometrium by interstitial bleeding—so-called Couvelaire's uterus. His maternal mortality in 88 severe cases was 4% after cæsarean section and 5% from vaginal delivery. For pre-eclamptic and eclamptic toxæmias he never performs section until the eclampsia is controlled. Among 879 cases of mild pre-eclampsia section was done in 61; and among 117 cases of severe pre-eclampsia section was done in 26—a high proportion, but 11 had antepartum hæmorrhage, 4 had disproportion, and 11 had other complications as coincident indications for operation. There were 341 cases of placenta prævia, and section was performed in 104 with no maternal death; of the 237 patients delivered by the vaginal route, 2 died.

These indications largely coincide with those accepted in Britain. Some British obstetricians are more conservative and some more radical, but we are tending to become more conservative with the toxæmias and a little more radical with placenta prævia. In this country we do either a classical or a lower-segment operation. Of the 2039 sections in Waters's clinic, 121 were classical, with a mortality of 6·6%; 28 were cæsarean hysterectomy, with a mortality of 10·7%; and 1 was a vaginal hysterectomy. The remainder were some type of lower-segment operation; 1406 were transperitoneal, with a mortality of 0·92%, and 483 extraperitoneal, with a mortality of 1·03%. For these 483 a supravesical operation was employed in 290 and a Latzko operation in 193; mortality from the former was 0·6% and from the latter 1·5%. These are excellent figures, especially for the extraperitoneal methods, which have perhaps not been given a fair trial by British obstetricians. Patients dying after cæsarean section usually die from peritonitis. Waters's contention is that if the peritoneal cavity can be completely avoided these women are being delivered in the safest possible manner, and his figures bear out his contention. The extraperitoneal operation is anatomically fairly difficult but is nevertheless within the powers of any man competent to open the abdomen.

MEDICAL PRACTICE IN NEW ZEALAND

A YEAR or two ago Mr. Douglas Robb, writing as a New Zealand surgeon, suggested[1] that the peculiar scope and discipline of general practice ought to be recognised as a specialty, and receive like rewards and status with other specialties. But he also felt that economic considerations should be secondary: we should be seeking first the *bene esse* of the different branches of medicine. Thinking along the same lines, he has now written on the place of the hospital in medical affairs.[2] The emphasis on organic illness, he says, has attracted much of the total energy of the profession, most of which is released in hospitals; and the hospital is the only professional corporate effort to which a doctor or nurse can belong:

> "A hospital post thus means much more than its face value. It represents social and professional prestige, and constitutes one of the vested interests, struggled for by those who have it not, and clung to by those who have. . . ."

Students grow up with the belief that the hospital teaching staff are the only men worth emulating; and, with notable exceptions, think of general practice either as a necessary evil or merely as a short cut by which they can earn enough to do something more agreeable.

In New Zealand social security legislation has obscured these trends: the large sums to be earned in general practice and midwifery have led to the neglect of specialist practice and salaried posts. But the results, Mr. Robb considers, are not good, in terms of the quality of the service given. The fact that payment is made o the number of acts done has led doctors to do personall "many trivial things which ought to be done by a nurs or a secretary, but are not so done because if the docto does them they are worth 7*s*. 6*d*. each." Easy mone and high taxation tempt doctors to refuse night calls and the genuine medical emergency is often ill served Nor is there evidence, he thinks, that the high reward have encouraged doctors to combine for the benefit o the patient, or even to relieve each other; or that th preventive approach to medicine has been favoured Relative and absolute neglect of the specialist and the salaried officer have brought a retrograde tendency towards the combination of specialism with genera practice, to the detriment of both branches. Established specialists can of course earn a good living in private work, but the young specialist is "haunted by the fleshpots of general practice"; and salaried officers are so poorly paid that it is becoming hard to fill their ranks. Yet "any effort to raise the financial status of, say, an M.O.H. disturbs a swarm of other public officials." Again there are too few men to fill the higher teaching posts and the better rewards of private practice draw many of the abler men away; though, as Mr. Robb says, the professor should be the best man of all.

To restore the balance in the various branches of medicine, and to transfer the emphasis from cure to prevention, he would like to see a unifying plan, managed in each area or region by one authority, the health board, which would control the money available for health services, assign their proper duties to hospitals and health centres, see that they were properly equipped, and ensure that they did their work efficiently. Representatives of technical personnel on the board would be elected by their groups—doctors, nurses, and technicians; and a majority of five seats out of nine, or seven out of thirteen, should be given to representatives of the public. Such an arrangement, he thinks, would be better than a lay board with professional advisory committees, because it would put a direct responsibility on the profession to see that the public are well served. A believer in group practice, he would like to see general practitioners working in health centres under good conditions, with time for leisure and study, and opportunities to take a higher degree in their subject. Specialist practice, on the other hand, would be largely confined to the hospitals, where it can be supported by adequate services and equipment.

SALUTE FROM THE BOWLER

Lieut.-General Sir Alexander Hood, director-general of the Army Medical Services, was last Monday presented by war-time Army consultants, now demobilised, with an album containing the consultants' photographs and records, and a sum of money which is to be used for a prize. Sir Heneage Ogilvie, who as a major-general was consulting surgeon to the Army in Africa, said that the presentation was intended as a reminder of a happy association. The British soldier had received better medical attention from the service directed by General Hood than had any other fighting man in history. Sir Alexander, in expressing his thanks, emphasised the value of the consultants' work, mentioning in particular their help with the *Army Medical Department Bulletin*, the useful meetings between them and consultants of the Allied Armies and representatives of the Emergency Medical Service, the Medical Research Council, and other bodies, and their influence in raising the standard of medical practice overseas.

DR. C. S. MYERS, F.R.S., died at his Somerset home on Oct. 12, at the age of 73. The first president of the British Psychological Society, he was until his retirement director of the psychological laboratory at Cambridge University, and principal of the National Institute of Industrial Psychology.

Parliament

THE BILL IN THE LORDS

Lord **JOWITT**, the Lord Chancellor, in moving the second reading of the National Health Service Bill on Oct. 8, said he was no iconoclast, but he did not doubt that our existing institutions must be modified and expanded to fit the new ideal of an integrated medical service. This was not a Bill to preserve ancient monuments.

Summarising the provisions of the Bill, he admitted that part v, dealing with the mental-health services, was obscure. But it was a temporary job and the Government hoped when time permits to review the legislation dealing with mental health. The language of the first clause, simple and curt as the Commandments, defined the greatest task ever placed upon the shoulders of any one man. If these duties were to be placed upon the Minister of Health he could not be denied the wide powers necessary to carry them out. According to the Bill the Minister would exercise these powers through regulations subject to the approval of Parliament, a method which would allow the administration to profit by experience.

THE MACHINERY

Our hospital system, he suggested, failed because it was not a system at all, and modern developments in medicine and surgery demanded more specialised organisations. Admission to a hospital was not enough; the patient must be admitted to the right hospital. Often where the need was greatest the resources were the least, and at present it was nobody's duty to see that hospital services were fairly distributed among the people. Whether we liked it or not, we could no longer run these services on the principle of "drop a shilling into my little tambourine." The proposals in the Bill for hospital administration, Lord Jowitt claimed, would provide an integrated system. The hospital management committees would act on behalf of the regional hospital boards, he hoped without undue interference from the boards, and, he was quite certain, without undue interference from the Minister. For services provided by local health authorities under the Bill reliance was placed, rightly he thought, on the larger units of local government. But the exact division of functions between the hospital side and the local-authority side obviously gave room for argument. For instance, tuberculosis and V.D. clinics had been placed on the hospital side of the line, though no doubt the hospital boards would make use of the health centres by agreement with the local health authority. The Bill expressly provided that the local authority need not themselves provide all these services. For home nursing or health visiting they could rely on existing voluntary organisations, such as the District Nursing Association.

For the general medical services new machinery had been set up to meet the doctors' unwillingness to be placed under the local authorities. No doctor would be compelled to enter the national scheme, but if he entered the scheme there must be two methods of control—the sale of practices was prohibited, and new entrants could not go to areas already fully covered and neglect areas which were not covered. A tribunal was also to be set up to investigate serious allegations against doctors. This machinery, the Government believed, would give full freedom, scope, and opportunity for the exercise of professional skill free from political factors or lay direction.

In paying the doctors the Government did not wish to rely solely on capitation fees; but while they wanted some element of salary they did not think that that should be the sole, or indeed the main, element. The Government would be foolish if they tried to construct this national health scheme on the basis of a disgruntled and dissatisfied profession, and for that reason they appointed the Spens Committee. They must try to arrange with the members of the profession themselves not only the range but also the method of remuneration, and the Minister, Lord Jowitt announced, was anxious to appoint a similar committee to deal with specialists' remuneration.

At every step the organisations in the scheme were interlocked, and its success would depend on the day-to-day coöperation of all the people working under it. He did not doubt that after this Bill had been threshed out all sections and classes of the community would sink their differences and press forward a great ideal for the betterment of the health of the people.

Party Criticisms

The Earl of **MUNSTER** asked whether it was merely for political and doctrinaire reasons that the whole of the medical profession were to be saddled with a system which they disliked, that institutions which the British people had so generously supported for centuries were to be removed from their control, and that fields in which local authorities had made much progress were to be taken over by the State. He did not believe that a single Government department could run a highly qualified and skilled service such as hospitals. Local administration might well require reform, but to transfer the whole hospital service to a single centre was to ensure that "wisdom at one entrance is quite shut out." For the Lord Chancellor to support such a proposal, he continued, as the confiscation of endowments for specific purposes must be unique in the history of trusteeship. Nothing could give less encouragement to the public to subscribe in future to any charitable enterprise. He did not believe that the Government could have done more to undermine the confidence of the medical practitioners, because the proposals for the general medical services offered no freedom of choice or movement, and little freedom of judgment, and pointed directly to the scheme becoming before long a full-time salaried service.

The Marquess of **READING**, speaking for the Liberal peers, supported the Bill in general terms, for, he pointed out, they had before them only the scenario of the ultimate Bill which would not have grown into its full splendour of technicolor for exhibition to adult and other audiences till 1948. The gaps would be filled by multitudinous regulations which would demand the closest scrutiny of both Houses. Of 74 clauses, 26 prescribed a regulation. He feared that before 1948 dawned not only the printing presses of the Stationery Office but the permanent officials of the Ministry of Health would be chronically overheated. Yet upon the good sense, good English, and foresight of these regulations the efficiency of the scheme would ultimately depend. He agreed that it was an anachronism that the health of the nation should continue to be left in the hands of voluntary organisations dependent upon charity. But he confessed that he found this rapacious engulfing of all the funds of the voluntary hospitals a considerable mouthful to swallow. Professional men were on the whole conservative—he did not mean politically Conservative, indeed from reading the papers lately he doubted whether anyone was politically Conservative any more—and some doctors were no doubt opposed to the scheme; but he hoped that discussions with the Minister would allay the fears raised by incautious utterances of some members of the Socialist party, and that the profession would lend itself with a good grace in the difficult circumstances at the outset to working the scheme, once satisfied that it was in the interests of the nation as a whole. He had a feeling that those who elected to reign in Hell rather than serve with Bevan would be few in number, secure in practice, and advanced in years.

The Archbishop of YORK, though impressed with the need for a national health service, feared that the Bill in its present form might undermine the independence of the medical profession. In these days when the State must own, control, and plan where once it only acted in a negative capacity, he attached great importance to preserving in the nation associations which had independence of their own. No doubt the Government's scheme made for efficiency, but sometimes efficiency could be bought at too great a price when it meant the loss of freedom.

Professional Criticisms

Lord MORAN, P.R.C.P., said that the surveys of the hospital service carried out during the war showed that drastic and expensive reorganisation was necessary. It was agreed that the money could only come from public funds, and that such expenditure must entail some measure of public control which could only be exercised by the Minister or the local authorities. The medical profession was in no doubt that it preferred the control of the Minister, and it was the removal of the dread that the hospitals might come under the control of the local authorities which had reconciled so many doctors to prefer the hospital provisions of the present Minister of Health to those of his predecessor. But there agreement ended. Many of his colleagues could not agree with the transfer of ownership of hospitals. They argued that the Minister should give the regional boards a block grant for distribution to the hospitals of the region, to be withheld from any hospital which did not put its house in order. But Lord Moran did not believe that any board, particularly one recently created, could thus apply sanctions to a powerful local authority, or that sanctions would be enough to bring about the drastic reorganisation which was essential. If, however, the medical profession felt that these hospital provisions were inevitable it did not mean that they were agreed that the particular provisions in this Bill would necessarily work.

The importance of the hospital service being a university service had, Lord Moran thought, received too little notice. Yet that was the original conception underlying the establishment of the regions. During the war specialists of every kind were sent by the teaching hospitals into the important hospitals in the region. They raised these hospitals almost to university standard. When they were called back at the end of the war he thought that doctors would agree that there was a sharp fall in the efficiency of hospitals at the periphery. In the past specialists had tended to congregate in the great centres. By a university service there could be a redistribution of specialists without duress, because men would willingly be seconded, feeling they were part of one great service.

If there was going to be this essential measure of centralisation in a scientific service, it was perhaps a paradox that there must also be a degree of decentralisation. The powers of the regional boards were but vaguely defined in the Bill. Suppose there was a complaint about dieting or nursing in a hospital, if the Ministry sent its own inspectors to investigate the complaint the board would lose authority. The Earl of Donoughmore had raised the point last April when nursing officers had been appointed who were to be the nursing authority in those regions. These officers would have the power to appoint and dismiss nurses. Were these officers going to exercise their powers through the regional boards, or independently of them? There was no guarantee that the Minister of Health would not interfere in clinical matters. That was not a fictitious vague fantasy; it had actually happened under the Emergency Medical Service during the war. The Minister must trust the regional boards, the hospitals, and the doctors to get on with their job.

THE DOCTOR'S LOT

Speaking of the doctors' fear that they would lose tl independence, Lord Moran agreed that if that happe the profession would indeed have received a mortal bl However effective the reformation of the health servi it would be of no avail if the conditions under wh doctors worked did not bring contentment and happin to them. Looking at this Bill, were these conditions s that the good type of man who had come into medic in the past would continue to enter it? In the innum able discussions on the Bill its effect on entry into t profession had hardly been mentioned. It was beca the Minister treated the teaching hospitals so sym thetically, and refused to blunt the growing edge medicine, that in the first instance many doctors examin the provisions of the Bill with sympathy. Those w worked in the academic world in medicine were perturb at present about the powers and composition of the boar that would govern the teaching hospitals. Medici in the past had been able to attract exceptional me Would it continue to do so? How were these gifted fe to be protected, and what did they want? First the B must be scanned to see that there was nothing in which encroached upon the leisure which the man ha given in the past to research. Leisure was going ou of the learned professions, to their detriment. Nowada the spare time of a specialist was taken up by attendan on committees, which were the drowsy syrup of tl democratic State. Many men with the greatest min were indifferent to material rewards, but it would b folly to handicap medicine in its competition with othe professions by a false parsimony. He had given notic to the Lord Chancellor that he would ask the Gover ment to appoint a committee on the lines of the Spe Committee to inquire into the remuneration of consultant and he was glad to hear that the Government had agree to that proposal.

At present the number of people seeking to ente medicine had leapt up, and though this was partly due t the effects of demobilisation Lord Moran thought i would continue, because in the past the entrants ha come from only a narrow section of the community many people being unable to afford the cost of training If the new entrants into medicine were to be subsidise by the State there must be new machinery for selection

Turning to the work of the general practitioner, Lor Moran pointed out that the present-day tendenc of patients who were gravely ill to seek institutiona treatment meant that the general practitioner saw a cas whisked out of his hands just when it became professionally interesting. The consultative service under this Bill would accentuate the difference between the general practitioner and the consultant. There was only one remedy. The general practitioner must be brought into the work of the hospital. Lord Moran confessed that he was less happy about the general-practitioner service planned in the Bill than about the hospital service, and that he was gravely disturbed by the fears of the general practitioners as to the future. They said they were against the abolition of the sale of practices, a measure of direction, and the basic salary. But all these came down to one fear—that there would be a whole-time medical service which would interfere with their liberty. He was certain that unless there was an adequate incentive to keep men on their toes, a whole-time service would be an incalculable disaster. In the unfortunate dispute that had arisen at the eleventh hour between the Ministry of Health and the panel practitioners Lord Moran was convinced that the doctors' claims were fair and just. But the dispute was not about terms but about procedure. The Minister wished to discuss the remuneration of panel practitioners at the same time as the remuneration of men in the future service, but the panel practitioners felt they had no mandate for this. Lord Moran was sure, however, that the Minister would meet the doctors' claims. It would be a disaster if the service were begun with some practitioners feeling that they had had a raw deal.

In medicine, Lord Moran ended, they always made a prognosis in a case feeling that they might be wrong. Men who knew the facts told him that if this service broke down it would be because there were not administrators to run it. If the Bill was to work something unusual must be done. He hoped the Minister would put into the service a small number of experienced men, trusted leaders of the profession, familiar with hospital work, who would give their whole time for about five years, to try to make the regions work. Many doctors working under the Ministry had not practised for 20 years. Men actively engaged in the profession were needed to come into the service. Only thus could the curtain be lifted which had fallen between the Ministry and the profession, leaving so much want of sympathy and understanding. Much of the criticism which the Bill had provoked seemed to him to be tethered to the earth; it had never become airborne, and it had been totally lacking in idealism. The politicians had made debating points and too many of the doctors had merely expressed their fears and prejudices. It had been left to the Minister to generate the momentum that overcame obstacles and to enlist the strenuous support of ardent minds. When it became law Lord Moran believed that despite all past differences the whole medical profession would unite to try to make the service a success.

Lord TEVIOT, speaking as chairman of the interdepartmental committee which had inquired into the condition of the teeth of the nation, described the need of the public for dental improvement as gigantic. The annual intake into the dental profession would have to be increased from 300 to 900.

Lord INMAN pointed out that today the voluntary hospitals were only partially voluntary; last year 45% of the income of Charing Cross Hospital came from public authorities and patients' payments. In a modern community, he believed, the heavy cost of curative and preventive treatment, of buildings and equipment, made financial demands which it was not within the power of voluntary effort to satisfy. This Bill would continue and expand the work of the hospitals, building on their tradition and experience a firm and worthy edifice of which this country would be proud in years to come.

PROPOSED AMENDMENTS

Lord HORDER, F.R.C.P., affirmed that the medical profession were not obstructionists. For the last 20 years they had done their utmost to persuade the powers-that-be to get a move on in integrating the medical services of the country. But the doctors had hoped that it would be through the more natural process of evolution rather than through the present method of revolution. The doctors thought they could have attained more certain benefits with less risk. They believed that they could have rationalised the hospitals without transferring their ownership to the State, covered the health of the dependents of the workers, set up health centres without sacrificing the doctors' liberty, and brought together in a comprehensive whole the industrial medical service and the medical services of the various Government departments. He agreed that this Bill enhanced one desirable thing—the availability of medicine to the citizen. But too much might be paid for that advantage, and it would be a loss to society if through this Bill medicine became stereotyped.

The ideal to be aimed at in framing a national medical service policy was not this terrific centralisation of power in one man, but a maximum of central direction and a minimum of central control. Closer contact with the medical profession during the framing of the Bill would have safeguarded Mr. Bevan and his successors from this danger. The Minister had spoken many times about his "consultation" with the profession, but that had been a euphemism for the most blatant form of *ipse dixit*-ism.

As soon as their Lordships had dealt with the Bill the doctors would be asked by a plebiscite issued by the British Medical Association if they would work the Bill. The answer to the plebiscite might even at this late hour be influenced by what happened during the committee stage in their Lordships' House, because Lord Horder hoped that the Government would sympathetically consider certain amendments to preserve the autonomy of the voluntary hospital, and to safeguard the freedom of the doctors. This Bill went far towards nationalising medicine. Whatever natural talent a doctor had, however ambitious he might be, he was condemned to a dead level of mediocrity. Not only his economic position but also his professional status and prestige had been given a ceiling. Unlike his fellow civil servants of the future, he was to have no chance of promotion. Lord Horder saw no escape from this state of affairs except through the medium of a black-market in doctoring, and his mind boggled at the thought of its probable immensity.

The Minister said it was not possible to insert the terms of remuneration in the Bill, but it should be possible to amend an existing clause so that the method of payment was stated, and this should be the capitation method unless, in the opinion of the executive council in whose area the services were rendered, a different basis was considered necessary. The prohibition placed on the selling of practices, the power of negative direction, and the refusal to allow a doctor charged with some offence under the Bill the right of appeal to the High Court, were surely matters that required amendment. Doctors thought that the standing advisory committees of the Central Health Services Council should be appointed by and take their references from the council, and that they should report through the council to the Minister. They also considered that the Minister should sacrifice his power to vary the proportion of medical and lay representatives on the local executive councils. To retain local interest, hospital management committees, acting for a group of hospitals, should appoint a house-committee in each hospital, subject to the hospital management committee and the regional board. It should also be one of the functions of the hospital management committee, or of the house-committee, to set up a medical staff committee with the right to nominate a reasonable number of its members to the hospital management committee or house-committee. On the side of medical education, the Bill also needed amendment, for it laid on the boards of governors of teaching hospitals no duties to further medical education and research. It was a glaring anomaly that gifts and legacies received by the non-teaching hospitals between the passing of the Act and the appointed day would go direct to the Hospitals Endowment Fund; whereas any gifts and legacies received after the appointed day would be retained by the management committee. We were about to embark on a great experiment, Lord Horder concluded, and it was the doctor's duty to do his utmost to make it succeed. If he could fulfil his paramount duty to his patients through these means he would; if not it would be for the patient to decide how long the sacrifice of efficiency should continue.

CHRONIC DISEASE

In a maiden speech Lord AMULREE, F.R.C.P., spoke of the condition of the chronic sick today. The transfer of the municipal hospitals to the central authority under the Bill would, he thought, benefit these people enormously. In 1944 there were about 60,000 of these patients in the whole country, of whom at least a third were under sixty-five. In some of the smaller institutions conditions were deplorable and no attempt had been made to classify the patients. Yet with a proper approach much could be done for them. In one big institution of which he knew, about 60% of the patients who came into the chronic sick ward were discharged into their own homes or into hostels for old people. When the Bill was passed he hoped the chronic sick would share the same medical staff as the acute sick. It was difficult to separate elderly people into the healthy and the sick, for when people grow old there was a narrow borderline between sickness and health, and there should be a simple and easy flow to and from hospital. Lord Amulree suggested therefore that sick and healthy old people should all come under the same authority.

The Second Day

The Earl of **Listowel** opened the second day of the debate by replying to some of the points raised. It was a misunderstanding, he said, to suggest that the Bill proposed that the Ministry of Health should run the hospitals. The Minister must—not may it should be noted—delegate his powers to the regional hospital boards, and from there to hospital management committees or, in the case of teaching hospitals, to boards of governors. The regional boards would not interfere in the affairs of these committees in the daily routine business of the hospitals. Their job was to supervise and plan for the region as a whole. There would be no financial leading strings, for each hospital committee would be free to decide how its money should be spent within the limits of the annual budget. The investigation of complaints and the engagement or dismissal of nursing staff would be delegated to the regions, and there was no real danger of Whitehall interfering in the domestic affairs of the hospitals.

The size of the regions had not yet been decided, but each would, so far as possible, centre upon a university; and after consultation with the interested parties the Minister would define the regions under regulations to be submitted to Parliament. Lord Listowel categorically denied that the Government policy was to institute a full-time salaried medical service, and he promised that when an allocation was made from the Hospital Endowments Fund the wishes of the donors would not be forgotten.

The Minister was anxious to break the deadlock that had arisen between the Ministry and the panel practitioners, and Lord Listowel announced that a meeting between Mr. Bevan and representatives of the profession would take place on Oct. 10. They were not dispensing, he added, with material or moral incentives to an efficient medical service, and there would continue to be a graduated scale of salaries in the hospital service and progressive remunerations for general practitioners.

By wider education and mass publicity campaigns it was hoped that the rising generation would grow up physically as well as mentally literate, and sufficiently sensible not to regard good health as merely a state of not being ill. The Bill was not the product of any single party or Government. It was the outcome of concerted effort over many years, involving doctors, laymen, and Governments, to improve the efficiency of our medical services and to make them more easily accessible to the public. A typically British scheme, it strove to incorporate in the new structure all the serviceable elements of proved usefulness in the old. If it moved a bit further in the direction of State medicine it still combined freedom, for doctors and patients alike, with overall planning, private with public practice, and unpaid voluntary service with salaried contractual obligations. It was as far from the all-embracing State system of medicine practised in Russia as it was from the commercial medicine favoured by the United States of America. By its inclusiveness, its more even distribution of the nation's medical resources, and most of all by breaking the cash nexus between medicine and the individual, the Bill would remove the gravest obstacle to equality of opportunity.

TO BE CONSIDERED IN COMMITTEE

Lord **Lyle** feared that even with amendments it would be impossible to make what was fundamentally a bad Bill into a good Bill. He regretted that a nation which had vanquished totalitarianism should propose to enslave its medical profession. Under the Bill the Ministry of Health would obtain dictatorial powers affecting the intimate lives and health of every single man and woman in the country. Lord **Beveridge** on the other hand thought it was a good Bill well worth making better by amendment. For the first time it set up a true Ministry of Health with the duty and power of attacking disease as a national enemy. Health as well as bread for everybody, he asserted, should come before cakes and circuses.

Lord **Uvedale**, F.R.C.S., in a maiden speech suggested that in an efficient medical service it was essential that every patient should be free from financial anxiety, and have a free choice of hospital and doctor. Admitted to hospital, he should find himself in pleasant sympathetic surroundings and free from unnecessary and irksome restrictions, for in sickness every man and woman was an individualist. It was also essential that the doctor should have independence in medical treatment, adequate equipment, and ancillary help. Remuneration must be sufficient to attract able men and women, and there must be opportunities for the gifted to attain positions of influence and distinction in the national life. Finally the medical profession must be controlled by the medical profession.

Lord **Luke** was disturbed by the hesitancy people were showing at present in subscribing to hospitals, and appealed to the Minister to evolve a formula for this interim period to prevent generous habits being broken. Lord **Addington**, speaking as a vice-president of the Association of Municipal Corporations, was distressed that the non-county boroughs should lose their maternity, child-welfare, and other health services. He would like provision made enabling the county councils to delegate their public-health functions to the non-county boroughs which had performed them efficiently. He felt that the local health authorities should be able to nominate their own representatives to the regional hospital boards, hospital management committees, boards of governors of teaching hospitals, and the central council. Lord **Llewellin** felt that the equalisation of the voluntary hospital endowments was not worth while in view of the difficulties it would create.

Lord **Jowitt**, in summing up, said he would not go through the detailed points, for they would be dealt with in committee. He promised careful consideration for their Lordships' amendments, but pointed out that great care had been taken in preparing the Bill and that the Minister had already made considerable concessions in another place. He agreed that doctors would much dislike to become salaried civil servants, and he reiterated that the Government had no such intention. If such a thing were done, he pointed out, it would have to be by a regulation which must be submitted to Parliament. In three respects the Government were accused of enslaving the doctors—by payment of part of their remuneration as salary, by negative direction, and by prohibition of the sale of practices. Taking a comparison from his own profession, Lord Jowitt asked if our full-time salaried judges were enslaved. County-court judges were even directed to certain regions. Were they enslaved?

He wished to underline everything that had been said about decentralisation. The nursing inspectors who had been appointed, for instance, were not inspectors in the ordinary sense. Their function was to go round to the matrons of the various hospitals to try to help them to get staff. Turning to hospital endowments he reminded their Lordships that if he were accused of taking sixpence out of the till he was putting a shilling on the counter, for he was giving from public funds far more than he was taking. When the Minister came to reallocate the funds he would consider whether a particular bequest was obviously for some local purpose. If so it might be treated differently from a bequest which was quite general.

The Bill was read a second time and committed to a committee of the whole House.

QUESTION TIME

Family Allowances

Mr. JAMES GRIFFITHS, Minister of National Insurance, in reply to questions, said he recognised that there had been some disappointment among those in receipt of payments under one or other of the existing social services which already include additions for children, because they have not continued to receive those additions over and above the new family allowances. It had, however, throughout been made clear that so far as existing schemes of social provision for risks arising in civil life provided specifically for children, payments under the Family Allowances Act would be in substitution for or would be taken into account in determining the amount of the additions made for children under other schemes. In the present transitional period improvements in one direction had been made in advance of others which would substantially benefit many of those now affected and would be brought in later under legislation already passed or to be passed. It was the Government's aim to build up the various schemes of social provision as a coördinated whole, and the place of family allowances in them must be looked at in relation not only to existing schemes but also to schemes still to be brought into force. The Government are examining the whole position from this point of view.

In answer to a further question, Mr. T. STEELE stated that, in accordance with the provisions of the Family Allowances Act, family allowances of 5s. were being substituted for children's allowances of 3s. for the second and subsequent children of widows under the Contributory Pensions Acts in about 35,000 cases.

Shortage of Medical Textbooks

Sir E. GRAHAM LITTLE asked the President of the Board of Trade if he was aware that the shortage of medical textbooks was a handicap to medical education, that many of the standard books in use by medical students were unprocurable, and that students and practitioners ordering them had been waiting nine months for delivery; and if he would take steps to remedy this position.—Sir STAFFORD CRIPPS replied: The main factors limiting the production of medical and other textbooks, for which there are increasing and accumulated demands, is the shortage of labour and of paper. The numbers employed in the printing and book-binding trades were still well below the pre-war strength, although the labour force increased, in July, 1946, to 74% of its pre-war figure. Publishers' regular paper quotas had been substantially increased over the last 18 months—from $42^1/_2$% to 60% of pre-war usage. In addition, it was open to any publisher who cannot bring out an important textbook merely from lack of paper to apply for a special allocation for that purpose.

Flour Extraction

Sir E. GRAHAM-LITTLE asked the Minister of Food if he would name the medical adviser mentioned in the secret instruction to Controlled Millers, C.M.C. 646, dated Sept. 19, 1946, as advising the reduction of extraction in national flour from the current 90% to 85%; why, in the same instruction, millers were informed that they must maintain the quota of chalk 14 oz. to 280 lb. in view of the explanation offered by his department that the quota had been doubled to meet the increased extraction of 90%; and whether he would decrease this quota of chalk pari passu with the decrease in the rate of extraction.—Mr. JOHN STRACHEY replied: The medical advisers mentioned in the instruction are the members of the Interdepartmental Standing Committee on Medical and Nutritional Problems. The original recommendation was that 14 oz. of creta præparata should be added to each sack of 280 lb. of 85% extraction flour, but in practice only 7 oz. was added. When the extraction-rate was raised to 90% the addition of creta præparata was raised to 14 oz. per 280 lb. on the grounds of the increased amount of phytic acid in the flour. Now the extraction-rate was being lowered to 85% it was considered inadvisable to lower the rate of addition of creta præparata below the original recommendation as alternative sources of calcium in the diet are short at present, but this course was subject to any further recommendation from the medical advisers.

Saving through Bread-rationing

Replying to a question, Mr. STRACHEY said that the saving in flour achieved by bread-rationing appeared to be about 214,000 tons so far, but he hardly thought that saving would continue at so high a rate.

Medicine and the Law

Alleged Cruelty to Cats

Dr. E. G. T. Liddell, Waynflete professor of physiology at Oxford, did not succeed in his appeal against the magistrates' decision convicting him of causing unnecessary suffering to cats kept by him in the animal-house of the university department of physiology. Quarter sessions, however, after a patient re-hearing which lasted nearly three days, reached findings which went far to justify his appeal. The fine of £25, imposed on him in the magistrates' court, was reduced to £5. The appeal of Mrs. Scragg, the woman who had charge of the cats and who had been fined £5, was allowed.

The allegations of cruelty were indicated in our account of the proceedings before the magistrates (*Lancet*, July 13, p. 61). Dr. Liddell, it may be recalled, was conducting research into the treatment of distemper in cats by sulphamethazine. At the recent quarter sessions the learned recorder held that Dr. Liddell had committed an error of judgment in putting too many cats into the enclosure while they were suffering from distemper. Apart from this overcrowding, said the recorder, Dr. Liddell had acted in a humane and proper manner; he had performed no cruel experiments; his treatment of the animals was a non-painful experiment, designed to cure the disease; none of the allegations against him, except the overcrowding, was proved.

The prosecution was undertaken by the Royal Society for the Prevention of Cruelty to Animals, whose inspectors gave evidence of what they saw when they visited the cats' compound. The recorder made the comment that he thought the witnesses for the society were entirely honest, but they were upset by the sight of this very distressing distemper "and failed, in my judgment, to distinguish between the natural symptoms of distemper, which it was impossible to cure while the disease was raging, and the further aspects of the disease."

An accusation of bad faith, made against Dr. Liddell, was satisfactorily disposed of. The prosecuting counsel had declared that Dr. Liddell was not conducting any experiment upon the cats and that his claim to have done so was an afterthought. The recorder said he accepted the evidence of Dr. Liddell and Mrs. Scragg in its entirety; "Dr. Liddell was conducting experiments on these cats and I accept his evidence entirely on that." There seems indeed to have been an element of exaggeration in the allegations. It was put in cross-examination to one of the society's witnesses that, out of eleven cats which, at the hearing before the magistrates, he had said would have to be destroyed, eight had since recovered. Sir Howard Florey, F.R.S., called on behalf of Dr. Liddell, observed at one point of his evidence that a lot of nonsense was talked by people who transferred human feelings to cats—a remark which involved him in an inconclusive argument with the society's counsel. The recorder put the matter more cautiously when, in deciding the case, he began by stating the opinion that charges of offences against animals often led to "public emotion" and to a certain "lack of judgment."

In England Now

A Running Commentary by Peripatetic Correspondents

THE other week I visited a recovery home for boys which was run, for no obvious reason, on ship's routine. Like all such things it was more naval than the Navy. Lads running up to my guide and asking "Permission to go ashore, sir?" took me back to previous years with a jolt. But it was a form of play-acting that appealed greatly to the boys and could be developed into a handy way of getting them to carry out the routine laid down for their recovery. When, however, it came to the doctor's pennant that was hoisted whenever a doctor came aboard I was out of my depth, my naval duties having always been on the dry side of high-water mark. The final ceremony, however, designed to promote His Majesty's good health, was in the true naval style and left all concerned in a happy frame of mind.

Why is it that some convalescent homes manage to make their inmates enjoy their stay while others just fail? At one institution, run by a religious order to provide convalescent women with a month at the seaside, the sister-in-charge seemed to be responsible for the happy atmosphere. Those who have never encountered religious sisterhoods expect a sister to be rather a remote other-worldly sort of being, but this one altered the visitor's ideas literally in the twinkling of an eye, for she certainly had a twinkle in hers. "You see," she explained, "I am lucky. This place was closed during the war, so I could start afresh and forget tradition. I don't have any rules—why should I? The patients are reasonable people who come here to rest. So I let them. I expect them to be in time for meals and not to sit up late talking—that's only normal good manners and they see the reason for it. Reading in bed? Well, I know they ought not to really, but nor ought I for that matter, and I do so like doing it. So I can't very well stop them." For all her light-hearted air she must have had many troubles in managing such a home in these days of rations, controls, and shortage of domestic staff. But she managed to look as though she hadn't a care in the world.

Then there was that other home, spotlessly clean, where a dozen women were taking a much-needed rest. Two elderly ladies were taking their elevenses in a peaceful sunny room. One of them, seeing a man being shown round, suspected (wrongly!) that he might be a prospective donor and took the opportunity to make a little speech, prefaced by a charming formal bob, saying how happy she had been there. She had never been away before and had come in some doubt and apprehension, but she had enjoyed herself immensely and was sorry to be going next day. "It's the Christian atmosphere that counts, sir," and with another bob sat down again. Here there was no question of a religious order and the atmosphere must have been the result of the unselfish labours of a small committee of local people with their hearts in the right place. There could be no question of a M.B.E. arriving, let alone a title. The work was its own reward. This must have a good deal to do with the secret. The weight of the work rests on voluntary workers who, I suppose, can be taken as the spiritual descendants of the religious orders of medieval days, so that we get back to a common ancestry for the inspiration of both institutions.

Since the dissolution of the monasteries such people have always worked in small and highly individualistic units. How will they fit into a large and tidy organisation such as is now projected? True, the religious orders were once the largest administrative units in the civilised world, but can the secret of organising such people in large units be recaptured, or will they always have to work on the fringe of the State's domain? For work they will.

* * *

The deadly nightshade seems to be commoner than usual this year. Have many cases of poisoning been seen? I am always surprised that people do die from eating these berries, for they do not taste at all pleasant, and a careful exploratory lick would reveal this without doing much harm. Unfortunately, some children will devour handfuls of a berry they have discovered in the hedge regardless of how it tastes, though at home the same children may be particularly finicky about their food.

The detective story in which the victim fell dead after one taste of a nightshade berry put among h fruit is as inaccurate as most accounts of sudden deat by poison. Cyanide is no doubt a pretty deadly substance, but in fact it is much slower than in fiction. I some metabolic experiments I had to kill some frog instantaneously to isolate certain normal substance from the tissues. When KON solution was squirted int their mouths they pulled a wry face, spat it out, hoppe off, and survived quite happily. An injection into th peritoneum caused death in about five minutes. The died in under a minute when it was injected intravenously. But it was quite different from the rich uncl who suddenly slumps into his chair in the library, and th detective notices "the pungent smell of bitter almonds."

* * *

A physician to a teaching hospital has only too many opportunities of appreciating the platitudinous observation that an old dog finds it difficult to learn new tricks And, with more or less justified self-pity, I have often when taking stock, considered what proportion of one's knowledge is in fact employed in the actual practice of one's professional life and what proportion represents a concession to the demands of the curriculum and the various examining boards. Such a reflection supplies an easy transition to a comparison between ourselves and the practitioners of our great sister profession. It will be recalled that, after twelve years' retirement from his practice at the Bar to devote himself to national service, Lord Simon returned to preside over a Court of Appeal in his capacity of Lord Chancellor. And, notwithstanding the interval, the great lawyer recommenced his legal activity in full flood. Instantaneously the cogs meshed; the intellectual machine resumed its work without friction. Suppose our profession to possess the analogous office. We are reminded in *Iolanthe* that the Lord Chancellor embodies the law. To suggest that after twelve years' retirement the Lord Physician or Surgeon could embody medicine or surgery would be too ridiculous for even momentary consideration.

The law, I take it, is very nearly static. Its basic principles remain unchanged; any alterations or accretions which result from newly established precedents are in substance comparatively trivial. The possession of judgment; the capacity of persuasive advocacy; the ability to present facts and arguments with clarity and conviction, in part natural talents, in part the result of practice and experience, are not necessarily prejudiced by a period of inactivity even as long as twelve years. But the art of the doctor is one of continuous progress. Admittedly, basic principles remain for all time, but the acceptance of discoveries and innovations is essential in the daily practice of any physician or surgeon. The physician who returned to practice after twelve years' absence would for a time be as puzzled as if he were transported to a strange land of people speaking a foreign tongue. He would be confronted with the names of "new diseases" which, though they must have existed in his day, had never been recognised. He would find that certain conditions which he had accepted as ætiologically obscure and incurable were being rapidly and completely relieved and sometimes even cured. Diabetes by insulin for example; addisonian anæmia by liver; myasthenia gravis by 'Prostigmin.' A vast therapeutic field presents itself under chemotherapy; another by the introduction of sex-hormones. Vitamins which occupied a few lines in the textbooks of his day, have now acquired a vast bibliography. At first he would be more ignorant and feel more helpless than a first-year student; or, to resume analogy with the other profession, a very young gentleman who has started to eat his dinners.

To what extent would adjustment be possible? Would he in time become again the great man of the day? I doubt it. For one thing, the influence of experience would compel a timid if prudent reluctance to accept all these panaceas, since experience recalls the precocious confidence in the value of so many cures which had failed in the test of time. Yes, the old dog learns new tricks with difficulty.

And so I turn with a sigh to master the principles of the rhesus-factor on which I am to lecture tomorrow. For even though by sedulous application I may grasp sufficient for this temporary purpose, I am most unlikely ever to carry its application into practice.

Letters to the Editor

ROYAL COLLEGE OF PHYSICIANS OF LONDON

SIR,—Certain members of the college have written to e medical journals about the representation of members the counsels of the college. They must know that e President took the initiative in calling a meeting of embers of the college in January. This was attended y three hundred members and a committee was ppointed to go into the matter. This committee eported to another meeting in April and their recommendations were accepted practically unanimously. The resident thereupon brought the matter before the ouncil of the college, who made recommendations to the omitia which involved alterations in the by-laws of he college, and this was put in hand at once. There s no reason to believe that the great majority of members re not satisfied with the procedure adopted.

A few members criticised the method of election of ellows but did not receive substantial support.

Royal College of Physicians,
London, S.W.1.

H. E. A. BOLDERO
Registrar.

CHILDREN WHO SPEND TOO LONG IN BED

SIR,—May I thank Dr. J. A. McCluskie for his most helpful article in your issue of August 31? In my three children, ranging in age from 6 years to 2 years, I have noticed many improvements since I cut down their sleep to the times he recommended.

I do not understand the difficulties of Dr. Catherine Storr (Sept. 7, p. 363), as the management of differing hours of sleep is just part of the household routine which must be followed if all the work is to be done; an understanding husband is of the greatest help in this connexion. Admittedly I have no small baby, but I have no help with the housework. I feel that when we have our next baby I shall be very glad of the guidance given by Dr. McCluskie in the difficult matter of infant sleep.

It is small wonder that the child propped in the pram, his toys around him, should go to sleep; he does so from sheer boredom. I have always left my infants (quite happy) in the playpen to play, even when they could only lie and kick.

It seems very surprising that a woman as busy as the one described by Dr. Storr should find time to stay in bed after 6 A.M. or have an afternoon rest. Perhaps Dr. McCluskie could give us some guidance on adult sleep requirements.

Pinner. BETTY AINSWORTH.

BOVINE PLASMA AGAIN

SIR,—There is a tendency to regard experiments done on the production of new blood-plasma substitutes as acts of supererogation, although it is conceded that such substitutes may be means of avoiding hepatitis and, less important, of relieving blood-donors of their heavy responsibility. I have long felt that a more favourable attitude is imperative, and anyone who has worked abroad among people who have an atavistic dislike to giving blood will agree. A dramatic presentation of the exsanguinated air-raid casualty will produce volunteer donors, but the equally pitiful case of a cholera patient raises different emotions. An efficient blood-plasma substitute which could be stored without refrigeration in outstation dispensaries and given with the same technique as a hypertonic saline would be one of the greatest blessings science could confer on doctors called on to deal with epidemic cholera or dysentery. The argument applies with equal force to the treatment of surgical and medical emergencies and the protracted treatment of nutritional hypoproteinæmias, biliary cirrhosis, &c.

Your annotation of Sept. 7, evoked by Dr. Massons's article in the same issue, gives certain criteria for assessing the suitability of plasma substitutes—i.e., non-antigenic, non-toxic, free from agglutinins (and hæmolysins), and of an osmotic pressure comparable with human plasma. To these I would add an extension of the criterion "non-toxic" and one further criterion.

The new criterion (making no claim for originality) is that the substitute is capable of being metabolised with profit by the patient. Obviously gum acacia, cellulose derivatives, and colloidal products of polymerised organic substances are excluded under this additional rule; but so is gelatin, which may still act very efficiently, in producing prolonged hæmodilution, but which is not metabolised (except perhaps when given with a mixture of amino-acids to make up for its constitutional deficiencies) and is in fact excreted in the urine almost cent. per cent. within 24 hours. Dr. Massons does not give data which would enable judgment to be passed from this point of view on his preparation of calf plasma. True he says that the results in the treatment of certain hypoproteinæmic conditions were as good as with human blood plasma, but American investigations have shown that it is extremely difficult to alter the plasma-protein concentration in such states by the administration of human plasma, so the only evidence, apart from the diuretic effects (which could equally well be produced by gum acacia), that true "profitable" metabolisation of the product occurs would be on the basis of nitrogen-balance experiments. This is a request for information and not carping criticism.

The extension of the criterion "non-toxic," possibly implied though not specified in the annotation, is that the substitute should not produce the syndrome which follows the use of macro-molecular substances such as gum acacia or even gelatin, which includes depression of plasma-protein production and prothrombin, an increase in the E.S.R., and a greater or less degree of blocking of the reticulo-endothelial system. Such an effect with colloidal solutions is to be expected unless the substance is metabolised, and each item in the syndrome can be of clinical importance, although these might justifiably be ignored when the infusion is not to be repeated, as in cases of surgical emergency. Cholera in a patient on the verge of, or actually in, a state of nutritional hypoproteinæmia presents such a condition where a further depression of plasma-protein production might just tip the scale between survival with rapid convalescence and death or a protracted convalescence. With salines only, such patients can die with a depressed blood-volume (dehydration) and simultaneous tissue or pulmonary œdema, and only human plasma or serum, or a metabolisable protein substitute, can be useful therapeutically.

Your comment that the osmotic pressure of such a preparation as Dr. Massons has described is probably less than that of human plasma is almost certainly erroneous. The denaturation increases the osmotic tension in this preparation to the extent of about 15% of the *total* osmotic tension of the original plasma, and the increase will be almost entirely due to a rise in the colloid osmotic tension. The probability is that the colloid osmotic tension of the preparation is well above that of human plasma. In any case, within wide limits determined largely by the amount of electrolytes introduced with the colloid, the actual colloid osmotic tension matters little.

Impressed by the great need for an easily available plasma substitute I have made several series of experiments under difficulties. In the first Colonel L. A. P. Anderson, I.M.S., then director of the Pasteur Institute, Shillong, and later director of the transfusion services, G.H.Q., Delhi, prepared bovine serum to which had been added 8·5% glucose and which was then spray-dried. This product was non-antigenic and non-toxic to guinea-pigs and could be sterilised by boiling. However, large-scale spray-drying was then impossible.

Later, after the publication of Edwards's article on "despeciated bovine serum," I started experimenting again and finally decided on egg-white as the protein basis because the whole process could be carried out easily and aseptically, the globulin could be precipitated by dilution with distilled water, and the complications of removing clot and corpuscles did not arise. This preparation was apparently non-antigenic and non-toxic and had quite phenomenal diuretic effects on patients with famine œdema when given as an approximately 5% solution in normal saline 300 c.cm. The criterion I insist on was not then applied for lack of facilities to work out a metabolic balance; neither was any estimate made of the effect of despeciation on the avidin (antibiotin complex).

An egg shortage and more work brought this experiment to an end! Although it sounds more bizarre even than bovine plasma, the application of denaturation to egg-white albumin might well be worth further study—a thing which I will certainly do unless someone better qualified and with better facilities does it first.

I am extremely glad that Dr. Massons has given us the details of his procedure and investigations into the properties of denatured calf plasma, and I hope that he will publish soon the metabolic studies complementary to its use in hypoproteinæmic states.

Brixham, Devon. R. Arthur Hughes.

TUBERCULOUS GLANDS AND CALCIFEROL

Sir,—In his letter of Sept. 28 (p. 473) Dr. Wallace writes that treatment of tuberculous glands with calciferol seems "helpful when sinus formation is present" but that it "has a clinically adverse effect on glands which have not broken down." He admits that this is "little more than an impression." I should like to record that in three cases of tuberculous cervical adenitis of the multiple type, without sinus formation, quite unsuitable for treatment by radical excision, there has been a markedly favourable response to calciferol, resulting in a reduction in size of the masses in the neck sufficient to excite pleased comment from the three patients concerned. It would be ridiculous to draw any conclusions from this. My sole purpose is to register an "impression" quite different from that of Dr. Wallace.

Dr. Wallace is right when he advises that calciferol should be given with caution when pulmonary tuberculosis is present, at any rate until more is known about its effect on this condition. On the theory that the beneficial effect of calciferol on lupus might be due to a specific effect on squamous epithelium I treated four cases of tuberculous laryngitis accompanying pulmonary tuberculosis by the administration of 100,000 to 150,000 units of calciferol daily. This treatment had to be abandoned after 5 days owing to undesirable toxic effects.

Though Dowling and Prosser Thomas[1] declare that the effect of calciferol on lupus does not seem to be related either to symptoms of toxicity or to the serum-calcium level, this point obviously requires further elucidation. Clinically, this might be done by treating a series of cases with parathyroid extract and large doses of calcium or by other measures designed to keep the serum-calcium at an abnormally high level.

Best and Taylor[2] point out that the overdosage effects of parathyroid and irradiated ergosterol are similar. Both cause the same degree of hypercalcæmia, hyperphosphatæmia, and a rise in the non-protein nitrogen of the blood. The symptoms during life and the post-mortem findings after poisoning with either material are identical.

A comparison of series of cases treated by the two methods might shed important light on the mechanism by which calciferol produces its effect on lupus lesions.

Neath, Glamorgan. T. Francis Jarman.

CONTRACEPTION WITH THE SILVER RING

Sir,—The medical committee feels that a warning should be given concerning the sudden revival of a method of contraception called the silver or Grafenberg ring.

This appliance consists of a small ring, composed of silver, platinum, or other metal, which is inserted into the uterine cavity, where its presence, provided it is retained, is intended to prevent the embedding of the fertilised ovum.

The advantages of such an unexacting method are so manifest that the device was fairly widely studied some fifteen years ago, both here and on the Continent. Unfortunately, the risks in its use have proved greater than were at first anticipated. In addition to the fact that, even in cases where the ring is retained, the failure-rate is high (at least 5%, the ring often being born with the baby), the incidence of pain, menorrhagia, and metrorrhagia has been considerable, and subacute infections and acute salpingitis have been caused in healthy nulliparous women. Moreover, the technique entails the utmost danger to women who have previously had, or who contract, gonorrhœa; one such patient required hysterectomy.

Within the last few months this device has achieved an alarming popularity, for certain practitioners claim it to be the method of choice, even for young nulliparous brides. Members of this committee have met with many cases of infective lesions occurring in such patients, which they will be happy to publish if it appears necessary. It is very difficult for the average practitioner to get guidance on such a matter, and, without it, he is at a great disadvantage when his patients claim to have had friends who have been highly delighted with the method.

In point of fact, no progress has recently been made in the essentials of the ordinary contraceptive technique for security, either some type of occlusive rubber ca must be used by the wife, in conjunction with a chemic spermicide; or a sheath, preferably with a spermicid must be used by the husband. Such methods are non injurious, and offer a high degree of safety (at leas 98% used over ten fertile years) provided they ar competently chosen and applied.

My committee would be grateful if you would allo this warning to reach fellow practitioners.

Family Planning Association,
London, S.W.1.

M. A. Pyke
Hon. Secretary.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

Sir,—In reading Mr. Hermon Taylor's article o Sept. 28 and your leader of Oct. 5 I was amazed by th omission of both to refer to previous American article *on conservative treatment. I have a reference date* 1943. A short note on the method describing a smal series was published in this country last year. Th impression given is that this is a new method invente by Hermon Taylor, which is wrong. Hedley Visick, o York, has adopted conservative treatment for all perfora tions as a routine for the last two years with, I believe uniform success. The results of all methods acknowledg the tremendous mortality associated with this catas trophe, a condition of affairs that is regarded wit equanimity by most surgeons in that the condition is as you point out, usually looked upon as only worthy o the attention of a house-surgeon or resident surgica officer. The normal operative mortality is 20%.

You refer to one or two series of operative results in early cases with a small mortality; that this need not be regarded as only to be achieved by a few is shown by my own series of 50 cases with 2 deaths in eight years, cases not selected and including perforations up to three days old. My own routine is to avoid general anæsthesia except in the young and healthy adult, and in all other cases to use spinal or local with morphine; this ensures the absence of those postoperative chest conditions which are so fatal. There is no way in which we can be sure that the perforation is sealed off. My last case was in a girl of 21, severely shocked and with a rigid board-like abdomen. Operation showed a large perforation in the anterior wall of the stomach into which one could put the tip of a finger. In my opinion it would have been criminal not to have operated on this girl. Two days later she was sitting up smiling and on a normal diet. In some cases we can assume from the mildness of the symptoms and the relative well-bei of the patient that it is justifiable not to operate, and following the lead of Visick I have treated 4 cases this year conservatively without a death, each being proved radiologically or at subsequent operation.

All surgeons should know that the use of a drainage-tube in a perforation is dangerous as well as useless. Subphrenic abscess and pelvic abscess occur where tubes are used, and intestinal obstruction frequently follows its use in the pelvis. I have not used a drainage-tube in a perforation for over ten years, and I have not had an intestinal obstruction and only one subphrenic abscess. It is unnecessary to use chemotherapy as a routine; as Patey recently pointed out, cases which have been on prophylactic penicillin and/or sulphathiazole will still develop chest complications, and I have had one postoperative death, following a gastrectomy where a chest complication was anticipated, where penicillin and sulphathiazole were both used from efore the operation and the patient died of a bilateral ronchopneumonia.

---

[1] Lancet, 1946, i, 919.
[2] Physiological Basis of Medical Practice, London, 1943, p. 1159.

After operation many cases develop pyloric obstruction, and the surgeon must be prepared to recognise this early and perform a further operation within a few days when it is clear that the stomach contents will not pass freely through a pylorus narrowed both by the original ulcer and by the sutures used to obliterate it. No-one who reopens an abdomen a few days after a perforation can fail to be struck by the clean appearance of the abdominal contents and the absence of adhesions, or to realise that it is unnecessary to remove the fluid present at the time of operation and to insert a drainage-tube with the object of letting it off. In any case a drainage-tube does not carry out this function since it is rare for more than a few ounces to exude from it.

My experience as R.S.O. in several hospitals taught me that the mortality following perforations was due to carelessness or ignorance on the part of the operator; the use of general anæsthesia in debilitated patients or those with chest or heart lesions; the failure to recognise postoperative intestinal obstruction until it was too late; the failure to appreciate that the pylorus might be mechanically obstructed; the inability to diagnose subphrenic abscess; and the insistence on draining pelvic abscesses when diagnosed suprapubically rather than through the rectum.

In a hospital where the operative mortality is the generally accepted one of 20%, conservative treatment should have no greater risk and may, by the avoidance of an operation, have a lower one. Where, however, the surgeon can be sure of a reasonable mortality of under 5% then it seems to me that conservative treatment should not be the routine but should be used in selected cases where the crisis of the disease is over and the patient is already recovering.

Halifax General Hospital. H. I. DEITCH.

CHILDREN IN DAY NURSERIES

SIR,—The argument in Dr. Hilda Menzies's paper of Oct. 5 is that since a substantial proportion of the children did not make satisfactory progress as judged by weight gains in the first or second 3 months after admission to the nurseries, and since the children had almost double rations compared with those under the care of their mothers, their unsatisfactory progress was more likely to be due to emotional disturbances than to "anything so simple as lack of proper food."

Broadly, Dr. Menzies found that approximately a third or a quarter of the children admitted at ages between 1 and 2 years had unsatisfactory weight gains in the first 3 months, and approximately the same proportion had unsatisfactory weight gains in the second 3 months. There is no information on fluctuations in weight growth of preschool-children in this country, but if the experience for preschool-children in other countries and for older children in this country can be taken as a guide, then the same sort of fluctuations could be expected for children under their mothers' care as were found for children after admission to the day nurseries.

The practical significance to health of short-term fluctuations in weight growth has not so far been satisfactorily explained. From a recent Australian study,[1] no explanation could be given of them in young children living in child centres; Bransby[2] found short-term fluctuations in weight growth in older children with a good health record and living in a good environment. By all accounts the latter children were happy and contented. The short-term fluctuations in weight growth of these two groups of children might, of course, have been due to emotional disturbances, but they might well have been due to some other physiological or environmental factor. Similarly, emotional disturbance or some other factor may have been responsible for the short-term fluctuations found by Dr. Menzies. Her argument concerning emotional disturbances would have been strengthened had data been presented to show that the children who were emotionally disturbed did, in fact, have unsatisfactory weight gains and vice versa.

[2] Bransby, E. R. *Med. Offr*, Sept. 22, 1945.

SIR,—I was extremely interested in the article by Dr. Menzies. It gives confirmation to a thesis on the dangers of separation anxiety in young children which I, in common with other psychiatrists, have held for some time now. My own observations were made on hospitalised children and are embodied in a monograph (Separation Anxiety in Young Children. Genetic Psychology Monographs, 1943). Others have written to you at different times, notably in connexion with the evacuation of children during the war, and a letter in the *British Medical Journal* (1939, ii, 1202) from Dr. John Bowlby, Dr. Emanuel Miller, and Dr. D. W. Winnicott is so apposite that I cannot forbear to quote at least part of it here:

> "There are dangers in the interference with the life of a toddler which have but little counterpart in the case of older children. . . . Apart from such a gross abnormality as chronic delinquency, mild behaviour disorders, anxiety and a tendency to vague physical illness can often be traced to such disturbances of the little child's environment [i.e., removal from home] and most mothers of small children recognise this by being unwilling to leave their little children for more than very short periods."

Though the findings of analytic psychiatry on this point have up to now been more or less disregarded, perhaps this corroboration of their views by Dr. Menzies's carefully recorded experience will call more attention to them. To quote again, this time from my own paper:

> "In these days with increasing interference of the State in the handling of even very young children it is as well to be aware of all the pitfalls involved. One cannot know too much of the consequences of interference when dealing with two such fundamental biological urges as the parental instinct and its counterpart . . . [the need for] security and dependence. . . ."

Leeds. H. EDELSTON.

SIR ALMROTH WRIGHT AND ANTI-TYPHOID INOCULATION

SIR,—I am much indebted to Dr. Leonard Colebrook for drawing attention in your issue of Sept. 14 to an apparent mis-statement in my *History of Medicine*. I admit that, on page 348, I have unwittingly conveyed the impression that Sir William Leishman was the originator of anti-typhoid inoculation "along with Sir Almroth Wright," although, on a previous page (288), I describe Sir Almroth Wright as "the pioneer of vaccine therapy and of anti-typhoid inoculation."

Of course the title of "originator," although I did not use that word, belongs to Sir Almroth Wright, whose outstanding achievement in the field of preventive inoculation is certainly a landmark in the history of medicine. Sir William Leishman, it would appear, simply gave his powerful support to the introduction of the method into the British Army. I need scarcely add that the paragraph will be revised in any future edition of my book.

Edinburgh. DOUGLAS GUTHRIE.

SPLANCHNIC BLOCK, ELECTROLYTE BALANCE, AND URÆMIA

SIR,—Recent correspondence on uræmia following trauma or abortion has suggested that this condition can be successfully treated by restoration of the renal circulation, either by splanchnic block or by correction of the electrolyte balance. While I do not propose to question the correctness of both these procedures, I should like to draw attention to their limitations.

Although successful cases of splanchnic block in the human have been reported, Porritt et al.[1] were not impressed by its use in the casualties from B.L.A. The reason for this failure lies in the fact that the kidney will withstand ischæmia for only a limited period,[2] and, should the renal circulation be deranged long enough to even than bovine plasma, the application of denaturation to egg-white albumin might well be worth further study—a thing which I will certainly do unless someone better qualified and with better facilities does it first.

---

[2] Allen, F. M. *J. Urol.* 1943, 49, 515. Scarff, R. W., Keele, C. A. *Brit. J. exp. Path.* 1943, 24, 147. van Slyke, D. D., Phillips, R. A., Hamilton, P. B., Archibald, R. M., Dole, V. P., Emerson, K. *Trans. Ass. Amer. Phys.* 1944, 58, 119. Badenoch, A. W., Darmady, E. M. (in the press).

I am extremely glad that Dr. Massons has given us the details of his procedure and investigations into the properties of denatured calf plasma, and I hope that he will publish soon the metabolic studies complementary to its use in hypoproteinæmic states.

Brixham, Devon. R. ARTHUR HUGHES.

TUBERCULOUS GLANDS AND CALCIFEROL

SIR,—In his letter of Sept. 28 (p. 473) Dr. Wallace writes that treatment of tuberculous glands with calciferol seems "helpful when sinus formation is present" but that it "has a clinically adverse effect on glands which have not broken down." He admits that this is "little more than an impression." I should like to record that in three cases of tuberculous cervical adenitis of the multiple type, without sinus formation, quite unsuitable for treatment by radical excision, there has been a markedly favourable response to calciferol, resulting in a reduction in size of the masses in the neck sufficient to excite pleased comment from the three patients concerned. It would be ridiculous to draw any conclusions from this. My sole purpose is to register an "impression" quite different from that of Dr. Wallace.

Dr. Wallace is right when he advises that calciferol should be given with caution when pulmonary tuberculosis is present, at any rate until more is known about its effect on this condition. On the theory that the beneficial effect of calciferol on lupus might be due to a specific effect on squamous epithelium I treated four cases of tuberculous laryngitis accompanying pulmonary tuberculosis by the administration of 100,000 to 150,000 units of calciferol daily. This treatment had to be abandoned after 5 days owing to undesirable toxic effects.

Though Dowling and Prosser Thomas[1] declare that the effect of calciferol on lupus does not seem to be related either to symptoms of toxicity or to the serum-calcium level, this point obviously requires further elucidation. Clinically, this might be done by treating a series of cases with parathyroid extract and large doses of calcium or by other measures designed to keep the serum-calcium at an abnormally high level.

Best and Taylor[2] point out that the overdosage effects of parathyroid and irradiated ergosterol are similar. Both cause the same degree of hypercalcæmia, hyperphosphatæmia, and a rise in the non-protein nitrogen of the blood. The symptoms during life and the post-mortem findings after poisoning with either material are identical.

A comparison of series of cases treated by the two methods might shed important light on the mechanism by which calciferol produces its effect on lupus lesions.

Neath, Glamorgan. T. FRANCIS JARMAN.

CONTRACEPTION WITH THE SILVER RING

SIR,—The medical committee feels that a warning should be given concerning the sudden revival of a method of contraception called the silver or Grafenberg ring.

This appliance consists of a small ring, composed of silver, platinum, or other metal, which is inserted into the uterine cavity, where its presence, provided it is retained, is intended to prevent the embedding of the fertilised ovum.

The advantages of such an unexacting method are so manifest that the device was fairly widely studied some fifteen years ago, both here and on the Continent. Unfortunately, the risks in its use have proved greater than were at first anticipated. In addition to the fact that, even in cases where the ring is retained, the failure-rate is high (at least 5 %, the ring often being born with the baby), the incidence of pain, menorrhagia, and metrorrhagia has been considerable, and subacute infections and acute salpingitis have been caused in healthy nulliparous women. Moreover, the technique entails the utmost danger to women who have previously had, or who contract, gonorrhœa; one such patient required hysterectomy.

Within the last few months this device has achieved an alarming popularity, for certain practitioners claim it to be the method of choice, even for young nulliparous brides. Members of this committee have met with many cases of infective lesions occurring in such patients which they will be happy to publish if it appears necessary. It is very difficult for the average practitioner to get guidance on such a matter, and, without it, he is at a great disadvantage when his patients claim to have had friends who have been highly delighted with the method.

In point of fact, no progress has recently been made in the essentials of the ordinary contraceptive technique: for security, either some type of occlusive rubber cap must be used by the wife, in conjunction with a chemical spermicide; or a sheath, preferably with a spermicide, must be used by the husband. Such methods are non-injurious, and offer a high degree of safety (at least 98 % used over ten fertile years) provided they are competently chosen and applied.

My committee would be grateful if you would allow this warning to reach fellow practitioners.

Family Planning Association,
London, S.W.1.

M. A. PYKE
Hon. Secretary.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—In reading Mr. Hermon Taylor's article of Sept. 28 and your leader of Oct. 5 I was amazed by the omission of both to refer to previous American articles on conservative treatment. I have a reference dated 1943. A short note on the method describing a small series was published in this country last year. The impression given is that this is a new method invented by Hermon Taylor, which is wrong. Hedley Visick, of York, has adopted conservative treatment for all perforations as a routine for the last two years with, I believe, uniform success. The results of all methods acknowledge the tremendous mortality associated with this catastrophe, a condition of affairs that is regarded with equanimity by most surgeons in that the condition is, as you point out, usually looked upon as only worthy of the attention of a house-surgeon or resident surgical officer. The normal operative mortality is 20 %.

You refer to one or two series of operative results in early cases with a small mortality; that this need not be regarded as only to be achieved by a few is shown by my own series of 50 cases with 2 deaths in eight years, cases not selected and including perforations up to three days old. My own routine is to avoid general anæsthesia except in the young and healthy adult, and in all other cases to use spinal or local with morphine; this ensures the absence of those postoperative chest conditions which are so fatal. There is no way in which we can be sure that the perforation is sealed off. My last case was in a girl of 21, severely shocked and with a rigid board-like abdomen. Operation showed a large perforation in the anterior wall of the stomach into which one could put the tip of a finger. In my opinion it would have been criminal not to have operated on this girl. Two days later she was sitting up smiling and on a normal diet. In some cases we can assume from the mildness of the symptoms and the relative well-being of the patient that it is justifiable not to operate, and following the lead of Visick I have treated 4 cases this year conservatively without a death, each being proved radiologically or at subsequent operation.

All surgeons should know that the use of a drainage-tube in a perforation is dangerous as well as useless. Subphrenic abscess and pelvic abscess occur where tubes are used, and intestinal obstruction frequently follows its use in the pelvis. I have not used a drainage-tube in a perforation for over ten years, and I have not had an intestinal obstruction and only one subphrenic abscess. It is unnecessary to use chemotherapy as a routine; as Patey recently pointed out, cases which have been on prophylactic penicillin and/or sulphathiazole will still develop chest complications, and I have had one postoperative death, following a gastrectomy where a chest complication was anticipated, where penicillin and sulphathiazole were both used from

Obituary

STANLEY WYARD

M.D. LOND., F.R.C.P.

Dr. Stanley Wyard, physician to the Cancer Hospital and the Princess Beatrice Hospital, London, who died on Sept 29, was a first-class physician whose clinical acumen was founded on experience as a clinical pathologist. The son of the late Rev. G. L. Wyard, of Bournemouth, he was educated privately and at the University Colleges of Cardiff and London. After graduating M.B. Lond. in 1909 he held house-appointments at the West London Hospital before taking up a research assistantship in pathology at Leeds. He returned to London to set up in consulting practice, joining the staff of the Bolingbroke Hospital, the Belgrave Hospital, and the Victoria Hospital, Chelsea. His earliest bent was thus for pædiatrics, but he retained his interest in pathology, and alongside his other work he found time to act as medical registrar at the Cancer Hospital, where he was later appointed to the staff. Besides the well-known *Clinical Atlas of Blood Diseases*, of which he was part author, he also published in 1927 a *Handbook of Diseases of the Stomach* which reflected his wise judgment and wide experience. The first world war interrupted his clinical work, for he served in France with the R.A.M.C. as a pathologist. In the last war he took on additional work as temporary consulting physician to Hounslow Hospital and, under the E.M.S., as physician at the South Middlesex Hospital.

His clinical work was characterised by the great interest he took over every aspect of each case, which won him the confidence of patient and doctor alike. Scrupulously upright and honest in all his dealing, as a colleague writes, "he had no axe to grind but just did a good job of work." With his command over affection and respect he made an excellent chairman of the medical committee at the Princess Beatrice Hospital, and until lately he also served as chairman of the board of management of the Victoria Hospital. Behind his quiet exterior he had tremendous moral courage, and when many months ago he realised that he was suffering from a fatal illness he told no-one inside or outside his family but carried on as long as he could with no change in manner or appearance. His ambition had been to retire when he was 60—just about his age when he died—and go to live in South Africa where he hoped to find leisure and light for his favourite recreations—photography and biology—and to continue his games of golf which the war had interrupted.

ARTHUR NORMAN BOYCOTT

M.D. LOND.

Dr. A. N. Boycott, who died on Sept. 17, was a well-known figure in St. Albans, where he had lived since his appointment as medical superintendent to Hill End Mental Hospital in 1898. The third son of the late Richard Boycott, of Rugeley, he was born in Lucknow in 1866 and was educated at Monmouth School, where he was a brilliant scholar and a good athlete. He qualified at St. Thomas's Hospital in 1888, winning the Cheselden medal in surgery, and in 1893 took his London M.D. After holding a house-appointment at St. Thomas's under Sir William MacCormac he went to Cane Hill Hospital in 1890 as assistant medical officer to start a long and successful career in mental diseases. At the age of 32 he was appointed to Hill End Hospital, where as the first medical superintendent he was responsible for organising and equipping the new hospital. He worked hard to raise the standard of medical and nursing care and to improve the welfare of his patients and his staff, and his kindly administration earned him a lasting reputation and affection. A member for many years of the Royal Medico-Psychological Association, he took a great interest in improving the training of mental nurses. In 1925 he retired from the superintendentship of the hospital, but he continued to work as a consultant to the Hertfordshire county council until the early years of the war.

Apart from his professional work Dr. Boycott had many other activities. As secretary and later treasurer of the St. Albans branch he was intimately connected with the Red Cross in Hertfordshire, and during the second world war he spent much time doing Red Cross work for the relatives of prisoners-of-war. He was also a governor of the St. Albans School and a trustee of the Kentish Educational Foundation. His friends in the profession and in St. Albans will miss him not only for his work but for his kindly quiet manner and his steadfastness.

In 1905 he married Lota, the eldest daughter of the late Edward Griffith Brewer, who survives him with their only daughter.

RICHARD JAMES CAMPBELL THOMPSON

C.M.G., D.S.O., M.D. DURH., M.R.C.P.

Lieut.-Colonel R. J. C. Thompson died on Oct. 2 in St. Thomas's Hospital, London, where he had been secretary to the medical school for over twenty years. Born in 1880, the son of R. P. Thompson, of Stamford, he came to St. Thomas's as a medical student in 1898 from Marlborough, and became a prominent member of one of the great rugby football teams which the hospital produced at that period. He qualified in 1904, and after doing hospital appointments in 1905 he joined the R.A.M.C. Five years later he was seconded to the Egyptian Army to serve on the Sudan Sleeping Sickness Commission where Andrew Balfour was one of his associates. As a result of the investigations of the commission extensive measures were introduced which have proved successful in controlling sleeping sickness in the southern Sudan. Returning to the R.A.M.C. in the first world war he established a reputation as commanding officer of one of the best casualty-clearing stations in France. An injury to his leg led to his being invalided out of the Service. From 1919 to 1922, while acting as physician and surgeon to the Royal Hospital, Chelsea, he took the M.R.C.P. and the M.D. Durh. To this period also belong his papers on the problems of old age. For a short time he practised in Bordighera, but his main life's work began when he returned to St. Thomas's Hospital as secretary to the medical school.

Tommy Thompson, as he was generally called, was a man big in physique and heart, whose charm of manner brought him friends wherever he moved. He had the power of evoking affection, and consequently willing work from all his staff and subordinates, and he filled his post as secretary with energy and success. The death of his only son, whose plane failed to return from an Atlantic patrol, was a crushing blow from which he never entirely recovered, and after he retired a few weeks ago from St. Thomas's he seemed to have little zest left for life.

HENRY BEECHER JACKSON

M.A. CAMB., M.R.C.S.

Dr. Beecher Jackson, who died in the Wilson Hospital, Mitcham, on Oct. 8, succeeded his father as coroner for Croydon, and together they held office for nearly sixty years. From Epsom College he obtained an open exhibition to Clare College, Cambridge, and on leaving the university he was admitted to the roll of solicitors. In 1918 he obtained his medical qualification at St. Bartholomew's Hospital, after serving in the first world war as a temporary surgeon in the Royal Navy. In 1919 he succeeded his father in the office to which he had an obvious vocation, and for which he had assiduously prepared himself by constant attendance at the London coroners' courts. He was noted for his attention to detail, his courtesy, and his consideration. In 1939 he presided over the Coroners' Society. He leaves a widow and one daughter.

". . . Rifle bullets kill men, but atomic bombs kill cities. Our defense is not in armaments, nor in science, nor in going underground. Our defense is in law and order. . . . I do not believe that we can prepare for war and at the same time prepare for a world community. . . . Science has brought forth this danger, but the real problem is in the minds and hearts of men. We will not change the hearts of other men by mechanisms, but by changing *our* hearts and speaking bravely."
—Prof. ALBERT EINSTEIN, *New York Times Magazine.*

cause massive degeneration of the kidney epithelium, death will certainly follow from accumulation of waste products.

I am hoping to show in a paper to be published shortly that in some cases, even if electrolyte-balance is established early, death from uræmia still occurs. Moreover, that when the syndrome is fully developed there is considerable risk in giving fluid intravenously, since not only is the alkali reserve, sodium and chloride, difficult to maintain but there is also danger of overloading the circulation.

The area and extent of the renal necrosis must be the factor which determines unassisted recovery, but if the accumulation of waste products—in particular potassium—can be removed until such time as the kidney regenerates there is greater chance of the patient surviving. An apparatus for such a purpose, consisting of pump and dialysing membrane, has already been put forward by Kolff and Berk[3] and recommended by Bywaters[4] and Snapper.[5]

Simplification and modification of these methods are now under consideration at this laboratory and show promising results.

Pathological Dept., Salisbury Infirmary, Salisbury. E. M. DARMADY.

PILONIDAL SINUS

SIR,—After reading the article on postanal pilonidal sinus by Patey and Scarff in your issue of Oct. 5 I cannot understand their readiness to relegate the developmental theory to a secondary place. They state that an uninfected sequestration dermoid—ought it not to be dermoid fistula or cyst?—is almost never encountered; but does not this depend on whether it is looked for? I have found a few, symptomless, in patients complaining of other conditions. It does not seem to be appreciated by many practitioners that the congenital opening is extremely small and sometimes multiple. I have seen an eminent rectal surgeon demonstrate, to his own satisfaction, that no external opening was present by using a probe with an end as big as a match-head. Another case recurred after a drastic excision which had left the congenital opening intact. To demonstrate this opening I find a fine straight sewing needle, used eye end first, a useful probe.

Patey and Scarff seriously suggest that the fine hairs found in this region are capable of penetrating the skin, but an examination of the hairs in the sinus will show that they are often of considerable length, and must have grown from the wall of the sinus. Their conclusion that the pilonidal sinus in the hand was due to puncture by a hair seems incorrect in view of the histological picture, which showed a hair follicle in the wall of the sinus. The explanation of the recurrent sinus, longer than the original, containing dead hairs may simply be that the upper end of the sinus was not excised; hairs and debris from the remnant continued to collect and formed a sinus in the dead space left by operation.

On the choice of operation your editorial puts the position fairly. If it is undertaken in the "cold" stage, with careful excision of the track and its offshoots and care in suturing to obliterate dead spaces, there should be no need for any of the fanciful operations devised.

Plymouth. EDRIC WILSON.

SIR,—Patey and Scarff state that this condition in the majority of cases is not of congenital origin. They base this dogmatic statement on the slender and inconclusive evidence of being unable to find an epithelial lining in 13 out of 21 cases, and a description of an interdigital sinus in a barber's hand.

In 1933 (*Brit. J. Surg.* 1933, **21**, 219) I fully described the condition under the title of Coccygeal Sinus, and (as I thought) conclusively proved with histological evidence that such sinuses are congenital in origin. They can, of course, be easily confused with other septic conditions. A coccygeal or pilonidal sinus is a definite clinical entity and is always characterised by one or several minute openings situated accurately in the middle line. It requires careful observation to detect these openings. I have seen them many times in the newbo the adult, and elderly, causing no symptoms whatev It is only when they become infected that they give ri to trouble, with the resulting secondary sinus lined wi granulation tissue.

I venture to suggest to the authors that if they we to restrict their observations to the true pilonidal sin and were to take serial microscopic sections of th excised tissue they would in all cases find the epithel lining. Having operated upon a very large series o these cases I am confident that the theory I advance is the true one.

It seems a pity that a paper emanating from th Bland-Sutton Institute of Pathology should make no reference to Sir John Bland-Sutton, that supreme an accurate observer, who in his classic book *Tumou Innocent and Malignant* regarded these sinuses as du to faulty coalescence of the skin. He even suggeste they were comparable to the interdigital pouch of th sheep and stated that similar interdigital pouches occu in connexion with webbed fingers in man.

Manchester. R. L. NEWELL.

DISTRIBUTION OF DISSEMINATED SCLEROSI

SIR,—Disseminated sclerosis is well known to be common in some countries (e.g., Switzerland) and very rare in others (e.g., South Africa). Its incidence varies also in different parts of a country, for it is more common in north than in south Switzerland.

Investigations at present being carried out indicate that disseminated sclerosis is relatively common in England, and that patients suffering from the disease number 2–4 per 10,000 population. There seem, however, to be certain parts of the country where it is much more common than this, and others in which it is rarely, if ever, seen.

Information regarding its geographical distribution is being collected here for research purposes, and if any doctor can give information regarding its local incidence, or has been impressed by its frequency or rarity in his district, we should be grateful if he would communicate with us. Areas of the country where the disease does not occur are just as important as those in which it is frequen

W. RITCHIE RUSSELL.

Radcliffe Infirmary (Neurology), Oxford.

EARLY OVULATION

SIR,—The conclusions that Dr. Sevitt draws in his article of Sept. 28 may be unintentionally misleading. He says: (1) ". . . ovulation can occur on any day of the first half of the cycle"; (2) ". . . it appears therefore that premature ovulation is not uncommon"; and (3) ". . . it follows that there is no safe period in the first half of the cycle."

Of his 10 cases there is not one with a normal menstrual history. All except 2 are menorrhagias, which may be due to an endocrine disturbance, as in fact he seems to prove with the sections. The other 2 were cases of severe leucorrhœa. One of the causes of "functional" menorrhagia is claimed to be an excessive development of the secretory endometrium. Dr. Sevitt seems to confirm this and even shows that ovulation seems to occur early in this type of case—i.e., the luteal phase lasts longer than the normal 14 days and presumably gives rise to an abnormally thick endometrium, though he has no sections to confirm this.

In case 6 he found an early secretory endometrium during the bleeding phase. I cannot see why he postulates a new corpus luteum, since the same findings can surely be expected with a persistent corpus luteum or with an incomplete shedding of the endometrium, imperfectly stimulated to secretion by the corpus luteum of the previous cycle. In case 9, the only evidence he gives for a "very early secretory phase" is vacuolation and basal nuclei with some dilated glands of the endometrium. This change can be produced by a high œstrogen blood-level in the absence of a functioning corpus luteum, and therefore ovulation.

I feel therefore that the conclusions I have quoted can stand only if the words "in some cases of menorrhagia" are added at the end of each.

Obituary

STANLEY WYARD

M.D. LOND., F.R.C.P.

Dr. Stanley Wyard, physician to the Cancer ospital and the Princess Beatrice Hospital, London. ho died on Sept 29, was a first-class physician whose inical acumen was founded on experience as a clinical pathologist. The son of the late Rev. G. L. Wyard, of ournemouth, he was educated privately and at the niversity Colleges of Cardiff and London. After raduating M.B. Lond. in 1909 he held house-appointments t the West London Hospital before taking up a research ssistantship in pathology at Leeds. He returned to London to set up in consulting practice, joining the staff f the Bolingbroke Hospital, the Belgrave Hospital, and he Victoria Hospital, Chelsea. His earliest bent was hus for pædiatrics, but he retained his interest in pathology, and alongside his other work he found time o act as medical registrar at the Cancer Hospital, where he was later appointed to the staff. Besides the well-known *Clinical Atlas of Blood Diseases*, of which he was part author, he also published in 1927 a *Handbook of Diseases of the Stomach* which reflected his wise judgment and wide experience. The first world war interrupted his clinical work, for he served in France with the R.A.M.C. as a pathologist. In the last war he took on additional work as temporary consulting physician to Hounslow Hospital and, under the E.M.S., as physician at the South Middlesex Hospital.

His clinical work was characterised by the great interest he took over every aspect of each case, which won him the confidence of patient and doctor alike. Scrupulously upright and honest in all his dealing, as a colleague writes, "he had no axe to grind but just did a good job of work." With his command over affection and respect he made an excellent chairman of the medical committee at the Princess Beatrice Hospital, and until lately he also served as chairman of the board of management of the Victoria Hospital. Behind his quiet exterior he had tremendous moral courage, and when many months ago he realised that he was suffering from a fatal illness he told no-one inside or outside his family but carried on as long as he could with no change in manner or appearance. His ambition had been to retire when he was 60—just about his age when he died—and go to live in South Africa where he hoped to find leisure and light for his favourite recreations—photography and biology—and to continue his games of golf which the war had interrupted.

ARTHUR NORMAN BOYCOTT

M.D. LOND.

Dr. A. N. Boycott, who died on Sept. 17, was a well-known figure in St. Albans, where he had lived since his appointment as medical superintendent to Hill End Mental Hospital in 1898. The third son of the late Richard Boycott, of Rugeley, he was born in Lucknow in 1866 and was educated at Monmouth School, where he was a brilliant scholar and a good athlete. He qualified at St. Thomas's Hospital in 1888, winning the Cheselden medal in surgery, and in 1893 took his London M.D. After holding a house-appointment at St. Thomas's under Sir William MacCormac he went to Cane Hill Hospital in 1890 as assistant medical officer to start a long and successful career in mental diseases. At the age of 32 he was appointed to Hill End Hospital, where as the first medical superintendent he was responsible for organising and equipping the new hospital. He worked hard to raise the standard of medical and nursing care and to improve the welfare of his patients and his staff, and his kindly administration earned him a lasting reputation and affection. A member for many years of the Royal Medico-Psychological Association, he took a great interest in improving the training of mental nurses. In 1925 he retired from the superintendentship of the hospital, but he continued to work as a consultant to the Hertfordshire county council until the early years of the war.

Apart from his professional work Dr. Boycott had many other activities. As secretary and later treasurer of the St. Albans branch he was intimately connected with the Red Cross in Hertfordshire, and during the second world war he spent much time doing Red Cross work for the relatives of prisoners-of-war. He was also a governor of the St. Albans School and a trustee of the Kentish Educational Foundation. His friends in the profession and in St. Albans will miss him not only for his work but for his kindly quiet manner and his steadfastness.

In 1905 he married Lota, the eldest daughter of the late Edward Griffith Brewer, who survives him with their only daughter.

RICHARD JAMES CAMPBELL THOMPSON

C.M.G., D.S.O., M.D. DURH., M.R.C.P.

Lieut.-Colonel R. J. C. Thompson died on Oct. 2 in St. Thomas's Hospital, London, where he had been secretary to the medical school for over twenty years. Born in 1880, the son of R. P. Thompson, of Stamford, he came to St. Thomas's as a medical student in 1898 from Marlborough, and became a prominent member of one of the great rugby football teams which the hospital produced at that period. He qualified in 1904, and after doing hospital appointments in 1905 he joined the R.A.M.C. Five years later he was seconded to the Egyptian Army to serve on the Sudan Sleeping Sickness Commission where Andrew Balfour was one of his associates. As a result of the investigations of the commission extensive measures were introduced which have proved successful in controlling sleeping sickness in the southern Sudan. Returning to the R.A.M.C. in the first world war he established a reputation as commanding officer of one of the best casualty-clearing stations in France. An injury to his leg led to his being invalided out of the Service. From 1919 to 1922, while acting as physician and surgeon to the Royal Hospital, Chelsea, he took the M.R.C.P. and the M.D. Durh. To this period also belong his papers on the problems of old age. For a short time he practised in Bordighera, but his main life's work began when he returned to St. Thomas's Hospital as secretary to the medical school.

Tommy Thompson, as he was generally called, was a man big in physique and heart, whose charm of manner brought him friends wherever he moved. He had the power of evoking affection, and consequently willing work from all his staff and subordinates, and he filled his post as secretary with energy and success. The death of his only son, whose plane failed to return from an Atlantic patrol, was a crushing blow from which he never entirely recovered, and after he retired a few weeks ago from St. Thomas's he seemed to have little zest left for life.

HENRY BEECHER JACKSON

M.A. CAMB., M.R.C.S.

Dr. Beecher Jackson, who died in the Wilson Hospital, Mitcham, on Oct. 8, succeeded his father as coroner for Croydon, and together they held office for nearly sixty years. From Epsom College he obtained an open exhibition to Clare College, Cambridge, and on leaving the university he was admitted to the roll of solicitors. In 1918 he obtained his medical qualification at St. Bartholomew's Hospital, after serving in the first world war as a temporary surgeon in the Royal Navy. In 1919 he succeeded his father in the office to which he had an obvious vocation, and for which he had assiduously prepared himself by constant attendance at the London coroners' courts. He was noted for his attention to detail, his courtesy, and his consideration. In 1939 he presided over the Coroners' Society. He leaves a widow and one daughter.

". . . Rifle bullets kill men, but atomic bombs kill cities. Our defense is not in armaments, nor in science, nor in going underground. Our defense is in law and order. . . . I do not believe that we can prepare for war and at the same time prepare for a world community. . . . Science has brought forth this danger, but the real problem is in the minds and hearts of men. We will not change the hearts of other men by mechanisms, but by changing *our* hearts and speaking bravely."
—Prof. ALBERT EINSTEIN, *New York Times Magazine.*

cause massive degeneration of the kidney epithelium, death will certainly follow from accumulation of waste products.

I am hoping to show in a paper to be published shortly that in some cases, even if electrolyte-balance is established early, death from uræmia still occurs. Moreover, that when the syndrome is fully developed there is considerable risk in giving fluid intravenously, since not only is the alkali reserve, sodium and chloride, difficult to maintain but there is also danger of overloading the circulation.

The area and extent of the renal necrosis must be the factor which determines unassisted recovery, but if the accumulation of waste products—in particular potassium—can be removed until such time as the kidney regenerates there is greater chance of the patient surviving. An apparatus for such a purpose, consisting of pump and dialysing membrane, has already been put forward by Kolff and Berk[3] and recommended by Bywaters[4] and Snapper.[5]

Simplification and modification of these methods are now under consideration at this laboratory and show promising results.

Pathological Dept., Salisbury Infirmary, Salisbury. **E. M. DARMADY.**

PILONIDAL SINUS

SIR,—After reading the article on postanal pilonidal sinus by Patey and Scarff in your issue of Oct. 5 I cannot understand their readiness to relegate the developmental theory to a secondary place. They state that an uninfected sequestration dermoid—ought it not to be dermoid fistula or cyst?—is almost never encountered; but does not this depend on whether it is looked for? I have found a few, symptomless, in patients complaining of other conditions. It does not seem to be appreciated by many practitioners that the congenital opening is extremely small and sometimes multiple. I have seen an eminent rectal surgeon demonstrate, to his own satisfaction, that no external opening was present by using a probe with an end as big as a match-head. Another case recurred after a drastic excision which had left the congenital opening intact. To demonstrate this opening I find a fine straight sewing needle, used eye end first, a useful probe.

Patey and Scarff seriously suggest that the fine hairs found in this region are capable of penetrating the skin, but an examination of the hairs in the sinus will show that they are often of considerable length, and must have grown from the wall of the sinus. Their conclusion that the pilonidal sinus in the hand was due to puncture by a hair seems incorrect in view of the histological picture, which showed a hair follicle in the wall of the sinus. The explanation of the recurrent sinus, longer than the original, containing dead hairs may simply be that the upper end of the sinus was not excised; hairs and debris from the remnant continued to collect and formed a sinus in the dead space left by operation.

On the choice of operation your editorial puts the position fairly. If it is undertaken in the "cold" stage, with careful excision of the track and its offshoots and care in suturing to obliterate dead spaces, there should be no need for any of the fanciful operations devised.

Plymouth. **EDRIC WILSON.**

SIR,—Patey and Scarff state that this condition in the majority of cases is not of congenital origin. They base this dogmatic statement on the slender and inconclusive evidence of being unable to find an epithelial lining in 13 out of 21 cases, and a description of an interdigital sinus in a barber's hand.

In 1933 (*Brit. J. Surg.* 1933, 21, 219) I fully described the condition under the title of Coccygeal Sinus, and (as I thought) conclusively proved with histological evidence that such sinuses are congenital in origin. They can, of course, be easily confused with other septic conditions. A coccygeal or pilonidal sinus is a definite clinical entity and is always characterised by one or several minute openings situated accurately in the middle line. It requires careful observation to detect these openings. I have seen them many times in the newbo the adult, and elderly, causing no symptoms whater It is only when they become infected that they give r to trouble, with the resulting secondary sinus lined w granulation tissue.

I venture to suggest to the authors that if they w to restrict their observations to the true pilonidal su and were to take serial microscopic sections of t excised tissue they would in all cases find the epithel lining. Having operated upon a very large series these cases I am confident that the theory I advanc is the true one.

It seems a pity that a paper emanating from t Bland-Sutton Institute of Pathology should make r reference to Sir John Bland-Sutton, that supreme a accurate observer, who in his classic book *Tumo Innocent and Malignant* regarded these sinuses as d to faulty coalescence of the skin. He even suggest they were comparable to the interdigital pouch of t sheep and stated that similar interdigital pouches occ in connexion with webbed fingers in man.

Manchester. **R. L. NEWELL.**

DISTRIBUTION OF DISSEMINATED SCLEROS

SIR,—Disseminated sclerosis is well known to common in some countries (e.g., Switzerland) and ve rare in others (e.g., South Africa). Its incidence var also in different parts of a country, for it is more comm in north than in south Switzerland.

Investigations at present being carried out indica that disseminated sclerosis is relatively common England, and that patients suffering from the disea number 2–4 per 10,000 population. There seem, howeve to be certain parts of the country where it is much mo common than this, and others in which it is rarely, ever, seen.

Information regarding its geographical distribution being collected here for research purposes, and if an doctor can give information regarding its local incidenc or has been impressed by its frequency or rarity in h district, we should be grateful if he would communica with us. Areas of the country where the disease does n occur are just as important as those in which it is frequen

W. RITCHIE RUSSELL.

Radcliffe Infirmary (Neurology), Oxford.

EARLY OVULATION

SIR,—The conclusions that Dr. Sevitt draws in h article of Sept. 28 may be unintentionally misleadin He says: (1) ". . . ovulation can occur on any day the first half of the cycle"; (2) ". . . it appears therefo that premature ovulation is not uncommon"; an (3) ". . . it follows that there is no safe period in th first half of the cycle."

Of his 10 cases there is not one with a normal men strual history. All except 2 are menorrhagias, whic may be due to an endocrine disturbance, as in fact h seems to prove with the sections. The other 2 wer cases of severe leucorrhœa. One of the causes of "func tional" menorrhagia is claimed to be an excessiv development of the secretory endometrium. Dr. Sevi seems to confirm this and even shows that ovulatio seems to occur early in this type of case—i.e., the lute phase lasts longer than the normal 14 days and presu ably gives rise to an abnormally thick endometrium though he has no sections to confirm this.

In case 6 he found an early secretory endometrium during the bleeding phase. I cannot see why he postu lates a new corpus luteum, since the same finding can surely be expected with a persistent corpus luteu or with an incomplete shedding of the endometrium imperfectly stimulated to secretion by the corpus luteu of the previous cycle. In case 9, the only evidence h gives for a "very early secretory phase" is vacuolatio and basal nuclei with some dilated glands of the endo metrium. This change can be produced by a hig œstrogen blood-level in the absence of a functionin corpus luteum, and therefore ovulation.

I feel therefore that the conclusions I have quote can stand only if the words "in some cases of meno rhagia" are added at the end of each.

W. P. HIRSCH.

London, N.W.6.

Notes and News

NURSERY WORKERS IN SCOTLAND

To ensure a sufficient supply of properly trained workers n nurseries, nursery schools, and children's homes, Mr. Joseph Westwood, Secretary of State for Scotland, has decided to stitute a new course for a nursery nurses' certificate to be warded to girls in nurseries of all types who have followed course of practical and theoretical training and have passed n examination conducted by a Nursery Nurses Examination oard which has just been set up. The course, details of which ill be announced later, will cover two years, and will include ractical work and training in nurseries or nursery schools, nd vocational study and general education. The age-limits ill be 15–25 at the start of training, and candidates will *robably be required to have completed three years in a* econdary school, and to serve for a probationary period efore being accepted. The written part of the first examinaion by the board—to be taken by girls already in training—ill be held on Nov. 16, and the oral and practical part on ec. 3, 1946.

FOR CHILDREN AT TROGEN

The Swiss exhibition of planning and building now open the Royal Institute of British Architects, 66, Portland lace, London, W.1, illustrates a pleasant contribution to nternational understanding in the section of child welfare nd youth service. This is the Pestalozzi children's hamlet t Trogen, Appenzell, where houses have been built on a lovely illside to receive children of various nations. Building is ot yet completed, but in each house 16 homeless children of oth sexes, ranging in age from 3 to 15, will live with foster arents, and some 400 children will be given something like normal home life for several years. Groups of houses will e occupied by children of one nationality, speaking their wn language and keeping their national character, but each group will take part in the central organisation—an international community of children.

The hamlet is voluntarily financed, and school-children and students from Switzerland, France, Holland, and Austria have volunteered to help in building it. The Swiss had much experience during the war in dealing with tens of thousands of refugee children; the hamlet is therefore being founded under happy auspices.

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND

The membership of this union has in the past year increased by 279 to a total of 5742. The surplus on the year's working was £727, and the total surplus of assets over liabilities now amounts to £35,048. The union has still further strengthened its position notwithstanding the loss of revenue through the waiving of subscriptions from members in the Forces, who numbered 1883 at the beginning of the financial year. These figures are given in the annual report, which also contains this advice to a member threatened with a claim: (1) to report all the facts to the secretary, and send copies of all records of treatment; (2) to obtain and forward any relevant hospital, X-ray, and other reports; (3) to make no statement which might later be construed as an admission of liability; (4) to send to the secretary, without replying to them, any letters received from patients or their agents in connexion with the case; and (5) not to divulge that he or she is a member of a defence union.

University of Cambridge

Titles of degrees were conferred on the following during the months of August and September:

M.B., B.Chir.—R. S. J. Baker, H. F. Barnes, K. A. C. Bowen, J. E. G. Brieger, F. M. Fountain, J. F. Grant, M. C. Hare, M. Hobson, P. A. Howard, E. G. Howe, G. M. Hunt, H. M. J. Lawn, B. M. Leach, J. Raymond, A. M. Sibly.

University of Sheffield

Dr. R. S. Illingworth has been appointed full-time professor in charge of the new department of child health. It is expected that Dr. Illingworth, who is now assistant to the Nuffield professor of child health in the University of London, will take up his duties in the New Year.

Dr. A. R. Kelsall and Dr. J. Pemberton have been appointed full-time lecturers in medicine.

British Social Hygiene Council

Dr. Fred Grundy, medical officer of health for Luton, has been [illegible] irman of the executive committee in the p[illegible] Otto May.

Royal College of Surgeons of England

A quarterly meeting of the council was held on Oct. 10, with Sir Alfred Webb-Johnson, the president, in the chair. Mr. J. P. H. Davies, of Lewes County School, was admitted as a Macloghlin scholar. Dr. R. J. Last and Mr. H. F. Lunn were appointed anatomical curators.

The council decided to hold an additional primary fellowship examination in January, and an additional final fellowship examination in February, 1947.

Diplomas of membership were granted to P. T. Ballantyne, Hans Dasch, and D. A. Richards.

Diplomas were granted jointly with the Royal College of Physicians to the following candidates:

D.T.M. & H.—C. G. Bree, D. J. Conway, Mudjdeddine Mir-Fakhrai, S. T. Nakib, C. J. A. O'Kelly, A. W. Woodruff.

D.O.M.S.—Solomon Abel, H. Y. Bakro, P. B. Banaji, Edgar Benjacar, W. M. de C. Boxill, Mary Campbell, Prem Chandra, D. G. Cracknell, R. P. Crick, P. R. Day, D. W. Degazon, K. J. L. de Silva, E. F. J. Dunlop, J. D. J. Freeman, A. I. Friedmann, J. G. Gillan, Irene D. R. Gregory, C. D. Gun-Munro, K. J. Higham, J. J. Kennedy, Marian Lones, Edward Lyons, R. L. McKernan, J. M. Mallett, R. M. Mathers, R. C. E. Moffat, Louis Mushin, J. M. G. Nixon, G. N. Pattison, A. J. G. Pullar, K. B. Redmond, H. N. Reed, Edward Riley, C. C. Ring, J. A. Robertson, M. J. Roper-Hall, E. L. N. S. Sack, John Smallpiece, Helen S. C. Smith, A. H. Staples, R. W. Stephenson, Charles Swanston, H. J. R. Thorne, O. R. Todd, H. J. Wales, E. P. Walsh, J. J. Walsh, W. F. Walton.

D.C.H.—Daphne S. A. Anderson, D. C. Arnott, Katharine M. D. Bailey, C. L. Balf, A. C. Blandy, Andrew Bogdanovitch, P. T. Bray, Lorna M. Brierley, Marion Brown, F. R. Buckler, A. E. Buckwold, D. J. Conway, N. J. Cook, Pamela J. Coope, Janet E. W. Copland, P. J. N. Cox, W. H. Craike, Rosemary Davies, Walter Dickson, J. H. Diggle, Margaret D. D. Dudley-Brown, Vera S. Emanuel, G. A. Emmerson, Ethel R. Emslie, Linde E. U. Ewald, Ruth M. Fawcett, A. A. H. Galley, W. H. Galloway, R. E. Glennie, S. G. Hamilton, J. D. L. Hansen, E. W. Hart, Denise O. Henry, Isabella Hood, A. M. Jelliffe, Marion E. Jepson, C. C. Joannides, A. O. John, Cyril Josephs, Nest Kahan, Gwendoline M. E. Keevil, Elizabeth M. Kingsley Pillers, Kathleen M. Lane, Margaret J. Lezema, H. A. Leggett, K. R. Llewellin, Muriel J. Lowe, Patrick Macarthur, Alison D. McDonald, N. R. McEvoy, Mary S. McGladdery, Bessie R. Mackenzie, Douglas McLean, Antoinette M. H. MacMahon, W. J. Matheson, J. B. Mehta, E. W. Miles, Mary Milnthorpe, Enid E. Mitchell, Lucille M. Morgan, J. M. Mounsey, Agnes D. D. Murray, P. J. O'Reilly, B. D. Patel, S. H. Patel, Jean W. Paul, J. D. Pickup, E. M. Poulton, P. J. Preston, Ruth Prothero, L. B. Robinson, Sutcliffe Rattle, Gwladys M. Sewart, Mary D. H. Sheridan, Katherine V. Smith, Helen M. Wagstaffe, H. R. E. Wallis, L. L. R. White, T. K. Whitmore.

D. Phys. Med.—J. H. Crosland, C. R. L. Orme, J. D. Stewart.

Scottish Universities By-election

Colonel Walter Elliot, F.R.C.P., F.R.S., will stand as Unionist candidate in the forthcoming election caused by Sir John Orr's resignation. Colonel Elliot, who is a graduate of Glasgow University, has been Minister of Agriculture (1932–36), Secretary of State for Scotland (1936–38), and Minister of Health (1938–40).

Society for the Relief of Widows and Orphans of Medical Men

At a meeting of the court of directors held on Oct. 9, with Dr. R. A. Young, the president, in the chair, it was stated that in the last half year £1940 had been given to widows in relief. Membership of the society is open to any registered medical man living within twenty miles of Charing Cross. Full particulars may be had from the secretary, 11, Chandos Street, London, W.1.

Empire Rheumatism Council

Mr. Aneurin Bevan and Lord Horder will receive the guests at the reception which is to be held at the Apothecaries' Hall, Black Friars Lane, London, E.C.4, on Monday, Oct. 28, at 4 P.M., to celebrate the tenth anniversary of the foundation of the council. The guests of honour will be Mr. M. G. B. Prytz, the Swedish minister, Prof. J. A. Höjer, chief medical officer of the Royal Swedish health department, and his deputy, Dr. B. Strandell, and Dr. Loring T. Swaim, of the American Rheumatism Association.

Family Allowances

That family allowances are intended to assist in improving the standard of health of the most needy section of the community and must therefore not be reduced for any reason, was the view expressed by the council of the Socialist Medical Association at their recent meeting. At present those receiving special allowances for tuberculosis, workmen's compensation, and other contingencies are liable to have their total income cut by the amount of the family allowance, robbing the latter of all the beneficial effects it was intended to have. The association supports the strong protests being made and asks that family allowances be given as a right and without any reference to the total income.

Lieutenants.—I. A. Khan, J. N. Ghosh, S. J. Mascarenhas.

INFECTIOUS DISEASE IN ENGLAND AND WALE

WEEK ENDED OCT. 5

Notifications.—Smallpox, 0; scarlet fever, 1079; whooping-cough, 1811; diphtheria, 319; paratyphoid, 20; typhoid, 11; measles (excluding rubella), 1781; pneumonia (primary or influenzal), 411; cerebrosp fever, 32; poliomyelitis, 23; polio-encephalitis, 2; encephalitis lethargica, 2; dysentery, 63; puerpera pyrexia, 163; ophthalmia neonatorum, 80. No case o cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on Oct. 2 was 839. During the previous week the following cases were admitted: scarlet fever, 56; diphtheria, 28; measles, 17; whooping-cough, 26.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 2 (0) from enteric fevers, 2 (0) from measles, 12 (3) from whooping-cough, 5 (0) from diphtheria, 39 (3) from diarrhœa and enteritis under two years, and 7 (1) from influenza. The figures in parentheses are those for London itself.

Leeds and Oldham each reported 1 death from an enteric fever. Liverpool had 7 fatal cases of diarrhœa and enteritis.

The number of stillbirths notified during the week was 253 (corresponding to a rate of 26 per thousand total births), including 33 in London.

Births, Marriages, and Deaths

BIRTHS

BELL.—On Oct. 11, the wife of Mr. A. C. Bell, F.R.C.S., F.R.C.O.G.—a daughter.

BURKITT.—On Oct. 7, the wife of Dr. Eric Burkitt, of Wimbledon—a son.

DENT.—On Oct. 4, the wife of Dr. Charles Dent—a daughter.

HALLPIKE.—On Oct. 6, in London, the wife of Dr. C. S. Hallpike—a son.

HART.—On Oct. 3, Dr. Bridget Hart (*née* Egan), the wife of Dr J. A. G. Hart, of Londonderry—a son.

HARWARD.—On Oct. 7, at Odiham, Hants, the wife of Dr. R. L Harward—a son.

HICK.—On Oct. 8, at Chippenham, the wife of Dr. A. P. Hick—a son.

LEIGH.—On Oct. 5, at Romsey, the wife of Dr. R. E. Derek Leigh—a son.

MITCHELL.—On Sept. 25, in London, the wife of Dr. Herbert Mitchell—twin sons.

MOLESWORTH.—On Oct. 7, at St. Albans, the wife of Dr. Dav Molesworth—a son.

MORGAN.—On Oct. 6, at Southborough, the wife of Dr. C. R. Morgan—a son.

MOSELHI.—On Oct. 5, at Carlisle, the wife of Dr. A. Moselhi—a daughter.

MOYNAGH.—On Oct. 4, at Bristol, the wife of Dr. Kenneth Moynagh—a son.

NOBLE.—On Oct. 3, the wife of Dr. Andrew Noble, Stonehaven—a son.

REILLY.—On Oct. 9, in London, the wife of Dr. M. C. T. Reilly—a daughter.

SCADDING.—On Oct. 12, in London, the wife of Dr. J. G. Scadding—a daughter.

SCHOFIELD.—On Oct. 4, at Harpenden, the wife of Dr. Theodore T. Schofield—a son.

SMYTH.—On Sept. 28, at Dublin, the wife of Lieut.-Colonel S. Smyth, I.M.S.—a son.

WOOLF.—On Oct. 5, at Edinburgh, Dr. Cecil Mary Drillien, wife of Mr. Barnet Woolf—a daughter.

MARRIAGES

CALDER—HERRIOT.—On Oct. 1, at Glasgow, Francis Robert Murray Calder, M.B., to Janet Whitson Herriot, M.B., captain R.A.M.C.

KONSTAM—RITCHIE.—On Oct. 12, at Alford, Aberdeenshire, Peter G. Konstam, F.R.C.S.E., lieutenant R.A.M.C., to She T. Ritchie, M.B.

O'NEILL—PEARSON.—On Sept. 30, in London, Desmond Fran O'Neill, M.C., M.B., to Ruth Mary Pearson.

ROCHE—HARDY.—On Oct. 4, in London, James Wallace Roche, M.B., to Margaret Joan Hardy.

WALTON—TRUMP.—On Sept. 21, at Salcombe Regis, Richard Walton, surgeon lieut.-commander R.N.Z.N.V.R., to Barbara Trump.

DEATHS

BAKER.—On Oct. 10, Arthur Ernest Baker, M.R.C.S., L.D.S., of Bromley, Kent, aged 83.

BEARD.—On Oct. 12, at Epsom, Frederic Beard, M.B. Camb., aged 84.

BRIGGS.—On Oct. 7, at Wigston, Christopher Duffield Briggs, M.R.C.S.

HARDWICK SMITH.—On Oct. 6, at Wellington, New Zealand, Henry Hardwick Smith, F.R.C.S.

HARVEY.—On Oct. 7, Willoughby Henwood Harvey, M.A. Camb., M.D. Toronto, of Cambridge, aged 65.

JACKSON.—On Oct. 8, Henry Beecher Jackson, M.A. Camb., M.R.C.S., aged 67.

MYERS.—On Oct. 12, Charles Samuel Myers, O.B.E., M.D., SC.D. Camb., F.R.S., of Minehead, aged 73.

RIPPON.—On Oct. 4, in London, Thomas Stanley Rippon, O.B.E., M.R.C.S., late wing-commander R.A.F.

ROYSTON.—On Oct. 6, at Moordown, Bournemouth, Charles James Royston, M.B. Aberd., aged 46.

CORONARY DISEASE

THE HARVEIAN ORATION OF 1946 *

Sir MAURICE CASSIDY
K.C.V.O., C.B., M.D. Camb., F.R.C.P.
PHYSICIAN TO H.M. THE KING; CONSULTING PHYSICIAN TO ST. THOMAS'S HOSPITAL, LONDON

HARVEY was one of the first, and perhaps the most amous, of the experimental physiologists; certainly he s the most venerated. Even after the lapse of three undred years our admiration for his genius is mingled ith affection engendered by the many endearing facets f his character. His operative technique was of necessity omewhat crude. For instance, in the introduction to *De Motu Cordis* he refers to Galen's experiment:

> "An artery having been exposed is opened longitudinally and a reed, or other pervious tube, is inserted into the vessel through the opening, and the wound is closed."

Harvey comments:

> "I have never performed this experiment of Galen, nor do I think it could very well be performed in the living body, on account of the profuse flow of blood that would take place from the vessel which was operated on."

In the second disquisition to Riolan, however, Harvey describes the performance of this operation and notes obscure pulsation of the artery distal to the "pervious tube," and that blood escapes in spurts from this distal portion on section of it. But he goes on to lament that "the effusion of blood from the wound confuses everything, and renders the whole experiment unsatisfactory and nugatory." When watching Dr. Crafoord, of Stockholm, excise an aortic coarctation, and perform the almost incredible feat of effecting an end-to-end anastomosis of the thoracic aorta above and below the coarctation (Crafoord and Nylin 1945), I thought how delighted Harvey would have been with this triumph of modern surgery. He would also have shared with us our admiration of the skill which enables the surgeon of to-day to undertake the ligation of the patent ductus arteriosus with little more trepidation than before appendicectomy. He would have joined with us in congratulating Blalock, who successfully anastomoses the innominate or the subclavian artery with the right or left pulmonary artery (Blalock and Taussig 1945), and thus relieves some of the inconveniences of Fallot's tetralogy.

Harvey would surely have appreciated splanchnic sympathetic resection as an interesting physiological experiment, and would, like us, have been delighted to hear that the extensive lumbodorsal splanchnic resection devised by Smithwick (1944) can rob essential hypertension of much of its terror, for some years at any rate. But perhaps Harvey's admiration would be tinged with a little not unnatural envy were he to witness the work of his successors in the field of experimental animal surgery —the work, for instance, of Murray, Wilkinson, and Macgregor (1938), of Toronto, who excise a portion of the mitral valve and repair it with a strip of external jugular vein, with complete recovery of the animal. What would Harvey have thought of Cutler's cardiovalvulotome, or of cardiac endoscopy as practised by Harken and Glidden (1943)? Who can doubt that before long the surgical treatment of valvular stenosis in man will become a justifiable and successful operation?

I have to confess that I have had neither the opportunity nor the aptitude to obey Harvey's injunction "to search and study out the secrets of nature by way of experiment," except so far as every clinician experiments in a desultory sort of way in respect of treatment. But at last we physicians are beginning to recognise the value of controlled, as opposed to haphazard, experimental treatment. The brilliant results of the treatment of bacterial endocarditis with penicillin under the ægis of Prof. R. V. Christie and his committee would not have been achieved so quickly or so successfully on the old haphazard lines.

PREVALENCE OF CORONARY DISEASE

For many years I have been especially interested in cardiology, and I have been impressed, like many others, by the increasing prevalence of coronary disease. Even during so short a period as the last twenty years this increasing prevalence seems to be beyond question. In the year 1926, 64,465 persons died in this country of all forms of heart disease. Ten years later this number was almost doubled, 126,584 to be exact. The figures for coronary disease are even more startling: 1880 died in 1926; 14,095 in 1936; and 19,496 in 1939. The crude death-rate from all causes per 1000 persons living fell from 22 in the decade 1851–60 to 12 in 1930, and has subsequently remained almost stationary at about that figure. The similar crude death-rate from heart disease, and particularly from coronary disease, has risen in a spectacular fashion during this period, especially during the last twenty years. In the case of coronary disease the figures increase rapidly year by year: 48 per million living in 1926; 148 in 1930; 473 in 1939.

Part of this rapidly increasing death-rate from coronary disease is no doubt attributable to the increasing age of the population. In 1900 there were 1,750,000 persons over 65 years of age in Great Britain; in 1937 there were over 3,750,000 (Dudley Committee 1944). It is true that the standardised death-rate, corrected for ageing, for policy holders of the Metropolitan Life Insurance Company (1946), of New York, shows a 70% decline for diseases of heart, arteries, and kidneys in 1940–45 compared with 1911–15. But this astonishing decline in mortality is for ages 1–74. When the figures for the different age-groups are examined, it is clear that the improved mortality affects chiefly persons up to the age of 25, and is no doubt attributable, in part at least, to more efficient treatment of the acute infections which are largely responsible for cardiovascular and renal deaths in this lower age-group. Between the ages 35 and 64 the standardised mortality among men shows little or no decline in the past two decades, and there is in fact an increased mortality now compared with the level reached in the early nineteen-twenties.

The crude death-rates in America, without correction for increasing age of population, have increased as they have done in this country; thirty-five years ago cardiovascular diseases accounted for less than a quarter of all deaths. Now they account for nearly half.

Part of this mounting coronary mortality has been ascribed by some to increasing accuracy of certification. But I cannot believe that increasing accuracy of certification can play a very important part. The position here is very different from that in such a disease as bronchial carcinoma, for example, where accurate diagnosis largely depends on refinements of investigation, such as are afforded by bronchoscopy and radiography. Angina pectoris is one of the easiest of all diseases to recognise. Its clinical features have been well known to every doctor since Heberden recounted them before this college in 1768. In most cases of angina pectoris electrocardiographic and radiographic investigations are superfluous aids to diagnosis.

Certainly the clinical recognition of coronary thrombosis has till recently been hidden from us. Though first well described clinically by Herrick (1912), its diagnosis did not become widespread in America till about 1920. Curiously enough it was not until 1925 that McNee brought to the notice of physicians in this country the clinical picture of coronary thrombosis as first described by the American cardiologists, and the rapid increase in the certification of deaths from coronary thrombosis since that date must be partly attributable to this. Even so, I have the impression that coronary thrombosis is

---

* Delivered before the Royal College of Physicians of London on Oct. 18.

Biochemical Society

A joint discussion on Quantitative Biochemical Analysis by Microbiological Response will be held by the Biochemical Society and the Society for General Microbiology at the London School of Hygiene, Keppel Street, London, W.C.1, on Saturday, Nov. 2, at 11.15 A.M.

Course on Diseases of the Chest

A course of lectures and demonstrations will be held at the London Chest Hospital, Victoria Park, E.2, on Fridays at 5 P.M., from November till March. Those to be given this year are: Nov. 1, Dr. S. Roodhouse Gloyne, Industrial Diseases of the Lung; Nov. 8, Mr. S. C. Suggit, Carcinoma of the Larynx and Pharynx; Nov. 15, Dr. Shirley Smith, the Heart in Pulmonary Disease; Nov. 22, Mr. Holmes Sellors, Surgery of the Heart; Nov. 29, Dr. J. R. B. Hern, Asthma; Dec. 6, Dr. Browning Alexander, Consideration of Diagnosis and Treatment of Lung Abscess; Dec. 13, Dr. Franklin Wood, Recent Advances in the Radiology of Lungs.

Field Marshal Montgomery on Morale

The Lloyd Roberts lecture will be delivered at the Royal Society of Medicine on Monday, Oct. 28, at 3 P.M., by Field Marshal Viscount Montgomery. His subject is to be Morale, with Particular Reference to the British Soldier.

At a scientific reunion of the Société Internationale de Chirurgie Orthopédique et de Traumatologie in Brussels on Oct. 3 and 4, Prof. Louis Ombrédanne was re-elected president, and Dr. Jean Delchef secretary-general; Prof. Harry Platt and Dr. San Ricart were elected vice-presidents; and Dr. Henry Meyerding, of the Mayo Clinic, was elected president of the next congress, which will be held in Amsterdam in September, 1948.

Medical Diary

OCT. 20 TO 26

Monday, 21st

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.2
5 P.M. Prof. Harry Platt: Localised Cystic Disease of Bone.

Tuesday, 22nd

ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P.M. Mr. Geoffrey Keynes: Surgery of the Anterior Mediastinum.
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
5 P.M. *Medicine.* Dr. Maurice Davidson: Judgment in Medicine. (Presidential address.)
LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.2
5 P.M. Dr. W. J. O'Donovan: Psychosomatic Dermatoses.

Wednesday, 23rd

ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P.M. Mr. A. C. Palmer: Ætiology, Symptoms, and Treatment of Procidentia.
ROYAL SOCIETY OF MEDICINE
5.30 P.M. *Endocrinology.* Mr. L. R. Broster, Dr. E. F. Scowen, Dr. F. L. Warren: Over-activity of the Adrenal Cortex.
RESEARCH DEFENCE SOCIETY
3.15 P.M. (26, Portland Place, W.1.) Prof. N. Hamilton Fairley, F.R.S.: War-time Research in Malaria and other Tropical Diseases of Military Significance. (Stephen Paget lecture.)

Thursday, 24th

ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P.M. Mr. W. B. Gabriel: Causation and Treatment of Anal Incontinence.
ROYAL SOCIETY OF MEDICINE
8 P.M. *Urology.* Mr. R. H. O. B. Robinson: Problems of Renal Lithiasis. (Presidential address.)
LONDON SCHOOL OF DERMATOLOGY
5 P.M. Dr. G. Duckworth: Virus Diseases of the Skin.
MEDICO-LEGAL SOCIETY
8.15 P.M. (26, Portland Place, W.1.) Mr. L. Le Marchant Minty, PH.D.: Legal Aid to Assisted Persons.

Friday, 25th

ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P.M. Mr. R. C. Brock: Surgery of Lung Abscess.
ROYAL SOCIETY OF MEDICINE
2.30 P.M. *Epidemiology and State Medicine.* Brigadier Tom Kennedy, Colonel Horsburgh, Colonel H. A. Raeburn: Health Problems in Germany.
5 P.M. *Pædiatrics.* Professor Debono: Kala-azar in Infancy.
ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh
8 P.M. Major-General P. H. Mitchiner: Aftermath of War in Medicine.

Saturday, 26th

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.1
2.30 P.M. Dr. F. R. Curtis: Venereal Disease in Occupied Germany.

Appointments

GOVAN, A. D. T., M.B. Glasg., PH.D. Birm., F.R.F.P.S.: director of research, Glasgow Royal Maternity and Women's Hospital.
GRIERSON, A. M. M., M.B. Edin., D.P.H.: deputy medical officer of health, City of Manchester.
HARTLEY, J. B., M.D. Durh., F.F.R., D.M.R.E.: radiologist (diagnostic department), Christie Hospital and Holt Radi Institute, Manchester.
LINDAHL, J. W. S. H., M.CHIR. Camb., F.R.C.S.: second laryngologist, King Edward Memorial Hospital, Ealing.
MAIN, T. F., M.D. Durh., D.P.M.: medical director, Cassel Hospital for Functional Nervous Disorders, Stoke-on-Trent.
PERCIVAL, R. C., F.R.C.S., M.R.C.O.G.: gynæcological surgeon, King George Hospital, Ilford.
WARIN, J. F., M.D. Leeds, D.P.H.: deputy medical officer of health, City of Leeds.

Guy's Hospital, London:
BAKER, C. G., O.B.E., M.D. Lond., M.R.C.P.: assistant physician.
BLACKBURN, GUY, M.B.E., M.CHIR. Camb., F.R.C.S.: assistant surgeon.
CRISP, E. J., M.B. Camb.: physician in charge of physiotherapy department.
DREW, A. J., F.R.C.S.: surgical registrar.
EVANS, P. R. C., M.D., M.SC. Lond., F.R.C.P.: director of the department of child health and physician to children's department.
HILLS, T. H., M.B. Lond., D.M.R.E.: director of department of diagnostic radiology.
HORTON, R. E., M.B. Lond.: surgical registrar.
KENSHOLE, H. H., D.S.O., T.D., M.R.C.S., L.D.S.: assistant dental surgeon.
KESSON, C. W., M.R.C.P.: children's registrar.
LILWALL, B. G. A., F.R.C.S.: surgical registrar.
NICHOLAS, C. P., F.R.C.S.: surgical registrar.
PRINGLE, K. E., L.D.S. R.C.S.: assistant dental surgeon in children's department.
RIPMAN, H. A., M.B. Lond., D.R.C.O.G.: obstetric registrar.

Royal Waterloo Hospital for Children and Women:
ANSON, B., M.R.C.S., D.A.: anæsthetist.
ARMSTRONG, J. R., F.R.C.S.: orthopædic surgeon.
BAYNES, T. L. S., M.D. Lond., F.R.C.S.: gynæcological registrar.
BLACKBURN, F. H., M.B. Durh., M.R.C.S., D.A.: anæsthetist.
BLOOM, ROSS, F.R.C.S.: surgical registrar.
BRADDON, I. G., M.R.C.S., D.A.: anæsthetist.
EXNER, G., L.D.S. R.C.S.: dental surgeon.
LANCKENAU, N. I., M.D. Lond.: physician in charge of physical medicine.
MYERS, G., F.R.C.S.: surgical registrar.
SPIERS, B. G., F.R.C.S., M.R.C.O.G.: gynæcological registrar.
WIGODER, L., M.B. Dubl., M.D.S.: dental surgeon.

Royal Sussex County Hospital:
ALLEN, T. S., F.R.C.S.E.: ear, nose, and throat surgeon.
BINNING, REX, M.R.C.S.: anæsthetist.
BOURNE, W. A., M.D. Camb., M.R.C.P.: physician.
CRAWFORD, J. H., M.R.C.S.: anæsthetist.
DOWNER, H. G., M.B. Melb., D.L.O.: ear, nose, and throat surgeon.
FORRESTER-WOOD, W. R., F.R.C.S.: surgeon.
FRASER, G. A., M.B. Edin., D.L.O.: assistant ear, nose, and throat surgeon.
JONES, E. C., M.B. Lond., M.R.C.S.: assistant dermatologist.
MCCURRICH, H. J., M.S. Lond., F.R.C.S., M.R.C.O.G.: surgeon.
MCGREGOR, H. G., M.D. Lond., M.R.C.P.: physician.
MILLINGTON, E., M.R.C.S., D.M.R.: radiotherapist.
PRICE, R. K., M.D. Lond., M.R.C.P.: physician.
WATT, A. W., M.B. Glasg., D.P.M.: psychiatrist.
WAUCHOPE, GLADYS M., M.D. Lond., F.R.C.P.: consulting physician.
WILLIAMSON, J. C. F. L., F.R.C.S., M.D. Camb.: assistant surgeon.

Warwickshire Hospitals Council:
BERRILL, T. H., M.B. Brist., F.R.C.S.: visiting general surgeon.
WATSON, A. J., M.B. Lond., F.R.C.S.: director of accident and fracture services.

Oldham Royal Infirmary:
DAVIES, J. H. T., M.B. Camb.: visiting dermatologist.
HESLOP, J. F., M.B. Manc., F.R.C.S.: visiting genito-urinary surgeon.
JELLY, G. O., B.M. Oxfd, M.R.C.P., F.R.C.S.: visiting surgeon.
KENYON, A. L., B.SC., M.B. Manc., F.R.C.S.: visiting surgeon.
MURRAY, A. R., M.B. Edin., F.R.C.S.: first assistant to orthopædic and accident service.
NICHOLSON, W. F., M.A., M.D., M.CHIR. Camb., F.R.C.S.: visiting thoracic surgeon.
NISH, J. N., M.B. Melb., F.R.C.S.: orthopædic surgeon.
RACKER, D. C., M.B. Manc., M.R.C.O.G., F.R.C.S.E.: visiting gynæcologist.
RICHARDSON, A. H., O.B.E., M.R.C.S., D.M.R.: visiting radiologist.
SMITH, V. T., M.D. Manc., F.R.F.P.S.: visiting ear, nose, and throat surgeon.
SYKES, R., B.SC., M.D. Lond., M.R.C.P.: visiting physician.
TAYLOR, W. V., M.B. Lond., D.M.R.: assistant radiologist.

Swansea General and Eye Hospital:
BOWEN, J. G., M.B. Lond., F.R.C.S.: assistant surgeon.
BOYLE, H. H., H.D.D. & L.D.S. Glasg., H.D.D. Edin.: surgeon dentist.
CELLAN-JONES, C. J., M.D. Durh., F.R.C.S.E.: surgeon.
DAVIES, V. J., M.D. Lond., F.R.C.S.E., D.R.C.O.G.: gynæcologist.
EVANS, I. Q., F.R.C.S.E.: assistant surgeon.
HOWELL, H. W., M.D. Lond., M.R.C.P.: assistant physician.
JONES, D. S., L.M.S.S.A., D.A.: anæsthetist.
JONES, G. W., M.R.C.S.: assistant radiologist.
JONES, W. H., M.B. Wales: anæsthetist.
MACLEAN, W., M.D. Manitoba, F.R.C.S.E.: surgeon.
MORGAN, J. O., L.D.S. R.C.S.: surgeon dentist.
TANNER, C. H., M.B. Lond., F.R.C.S.: assistant surgeon.
THOMAS, I. J., B.S. Lond., F.R.C.S., F.R.C.S.E.: assistant gynæcologist.

today no-one would contend that men work four times as hard as women; in fact some might argue that the reverse is true. I have not been able to satisfy myself that the incidence of angina on women has increased of recent years compared with that on males. If smoking plays an important part in the causation of coronary disease, which I doubt, we should certainly expect a more equal sex-incidence during the next ten years or so.

Nor is there any satisfactory explanation of the unquestionably heavier incidence of coronary disease on the non-hospital as opposed to the hospital population.

Age-incidence.—My figures are much the same as those of the Mayo Clinic:

Age	Under 30	30–40	40–50	50–60	60–70	70–80	80
Females ..	0	1·3%	11·7%	29%	39%	15%	4%
Males ..	0·2%	3·2%	14·0%	33·9%	36%	11·1%	1%

About 70% of all patients were aged between 50 and 70 at the onset; 58% of women and 48% of men were over 60 at onset, which confirms the general impression that coronary disease tends to become manifest at a later age in women than in men. In 26 males the age at onset was under 40, in 2 under 30, the youngest being 26. There were only 3 women under 40 and none under 30.

It has become evident that coronary disease in young subjects is not so rare as used to be thought. French and Dock (1944) have reported 80 cases of coronary disease in American soldiers aged 20–36 during the recent war, and Newman (1946), in this country, 50 cases of coronary occlusion in Service men and women, aged 25 or less. Of Newman's patients 22 were under 30, the youngest aged 20. At autopsy atheromatous changes were found, in several instances accompanied by extensive calcification.

Stolkind (1928) reported 4 personal cases of angina in children and collected a further 25 cases from the literature. Many of these cases were in rheumatic children, and in some the evidence of angina was not very convincing.

Family history plays a notorious part in the ætiology of cardiovascular disease, and it did so in almost exactly half my cases. But this leaves another 50% of patients whose coronary disease cannot be attributed to inheritance.

Stress.—Mental or physical stress is often thought to be responsible for early cardiovascular death, and coronary disease has been brought into the ever-increasing ambit of psychosomatic disease (Halliday 1945). But does the population really work harder or live more strenuous lives than their grandfathers did? I sometimes doubt it. Certainly we eat and drink much less than they did. I have looked carefully through the histories of my patients, and in only 20% of them do I find evidence of subjection to outstanding stresses. Many of them in fact seem to have lived remarkably placid and sheltered lives. Dr. Paul White, of Boston, on a recent visit to this country told us that in the first edition of his book *Heart Disease* a sentence emphasising the relationship between angina and stress was in italics, in the second edition in ordinary print, and in the third deleted.

Nor am I familiar with the "coronary-disease personality," as described at some length by Arlow (1945):

> "A stubborn self-willed child who early entered into competitive relationship with a much feared and envied parent; the conflict is repressed and identification made with the parent. . . . He attempts to equal his superiors, to surpass and dominate others. A masochistic trend may be noted in the manner in which these patients neglect themselves and make themselves martyrs to their own ideals. . . . The compulsive striving for achievement and mastery never seems to end. Success brings no gratification nor release from tension."

Tobacco has long been thought to be a factor in the causation of arterial spasm, and there seems to be convincing experimental evidence of this. Numerous workers—e.g., Stewart et al. (1945), Evans and Stewart (1943), and Roth et al. (1944)—have demonstrated that the smoking of two cigarettes usually lowers the peripheral skin temperature, diminishes the peripheral blood-flow, and raises the systolic, and still more the diastolic, blood-pressure. It is said that these changes may be evident not only during the smoking of the cigarettes but also sometimes for as long as 30 minutes subsequently. This is depressing information to the smoker, but he will be encouraged to hear from Goetz (1942) that very similar results are obtained if the subject is alarmed, or asked to do a difficult sum, or even to take a series of deep breaths. Goetz concludes that the driving of a car in traffic would produce more adverse circulatory effects than the smoking of several cigarettes in an armchair at the club.

I always advise sufferers from intermittent claudication to stop smoking, and usually this brings no amelioration of their symptoms. But very occasionally the results are dramatic, and I have seen a relapse if smoking is resumed. So far as so-called "tobacco angina" is concerned, I have never encountered such a condition, and certainly I have never seen angina cured by stopping smoking. Statistically 17·6% of my coronary patients were non-smokers, 42·6% smoked moderately—i.e., not more than twenty cigarettes a day—and 39·8% were heavy smokers. As a control I investigated the smoking habits of a small series of non-cardiac cases, and found much the same figures.

PROGNOSIS

Coronary disease persisted more than twenty years in 11 of my patients, more than thirty years in 2 of them. The record duration was fifty-two years, in a lady who had her first attack of angina at the age of 30; she was leading a busy life at the age of 80, though still liable to angina whenever she walked. She died suddenly at the age of 82.

It has long been known that quite extensive coronary disease is compatible with an active life and need not necessarily be associated with angina. In fact this used to be put forward as an argument against the view that angina is due to coronary ischæmia. Coronary occlusion often antedates angina. It did so in 225 (22·5%) of my cases. Yet before coronary occlusion can occur there must almost always be coronary disease. Moreover, a remarkably complete functional recovery is possible after a coronary occlusion. One of my patients played vigorous games after a coronary occlusion at the age of 39. He had a second attack at the age of 48, and, against advice, was playing tennis regularly two years later, without any angina. Now at the age of 58 he is at work, plays golf, and mows his lawn without cardiac symptoms.

It is common for coronary disease to be entirely latent till sudden death takes place. Professor Hume, of Newcastle, tells me that since 1911 he has performed or attended post-mortem examinations on 160 miners who had died suddenly and unexpectedly in the pit or in close proximity to it. The cause of death in each instance was coronary atheroma, and most of the men had been working regularly, without complaint, up to the moment of their fatal collapse. Only 40 had premonitory symptoms. In 1 case there was a clear history of an attack of coronary thrombosis two years previously, after which the man had resumed his normal work in the mine and continued it till his sudden death. In about half the 160 cases there were old fibrotic scars in the heart muscle.

The explanation of coronary disease without symptoms is presumably that a wonderfully efficient collateral circulation may be formed if arterial obstruction develops sufficiently slowly. As Lowe and Wartman (1944) point out:

> "Complete obstruction may, gradually produced, effect no disturbance whatever in the blood-supply to the tissue. On the other hand, should the parent vessel supplying the anastomotic circulation become suddenly blocked, the

far more prevalent than it was. Looking through my notes of patients seen twenty or thirty years ago, I come across occasional cases where I failed to recognise the coronary thrombosis, which now, on paper, is the obvious diagnosis. But such cases are surprisingly few. It is interesting to read now James Mackenzie's notes of case 112, one of the 160 case-records in his book on *Angina Pectoris* (1923). He describes this as " one of the most puzzling cases I have met." It is now evident to us that this patient had at least two attacks of coronary infarction, the second associated with pericardial friction, and that six months later the consequent myocardial degeneration brought on three attacks of acute pulmonary œdema, the last fatal.

It is odd, too, that coronary thrombosis figures so seldom in the post-mortem reports of thirty years ago, despite the fact that the very astute morbid anatomists of those days were fully alive to the existence of this condition.

Consider, too, the clinical experience of great physicians of the past. Mackenzie (1923) states that " 380 patients consulted me for angina pectoris." Osler (1910) says:

> " It is a disease for seniors to discuss, since juniors see it but rarely; indeed I had reached the Fellowship before I saw a case in hospital or in private practice. During ten years I did not see a case at the Montreal General Hospital, and only one case at the University Hospital, Philadelphia. . . . A consultant in active practice may see 10, 15, or more cases in the course of a year, and this is about the figure reached in this country by a consultant with recognised cardiovascular leanings."

He goes on to say that he has now seen 268 cases, which included 42 " of the mild neurotic or pseudo form." Contrast these figures with those of the modern cardiologist, who counts his coronary patients by thousands rather than by hundreds, and remember that *there was but one James Mackenzie, and one William* Osler, whereas the modern cardiologist's name is legion! During the ten years 1898–1908 Sir Richard Douglas Powell (1909) saw 96 cases of angina, 26 of which he classified as vasomotor angina. Surely Osler, Mackenzie, and Douglas Powell were at least as competent to diagnose angina pectoris as are physicians of this generation.

DIAGNOSIS

What is the explanation of the increasing prevalence of coronary disease? In an attempt, and I confess at once a vain one, to find some answer to this question I have analysed the notes of 1000 cases of coronary disease, including both coronary occlusion and angina pectoris, seen in consulting practice. I have notes of approximately another 1000 cases which I have not analysed. I was careful to include only those cases where I was reasonably certain that coronary disease was present. And here may I put in a plea for the abandonment of such terms as angina minor, angina innocens, and (worst of all) pseudo-angina? Either the patient has angina—or he has not. If he has, we believe that some portion of his myocardium is ischæmic, usually as a result of coronary atherosclerosis, with or without a coronary thrombosis or a subintimal hæmatoma. Syphilis is a rare cause of true anginal pain, and embolism a rarer cause still. A severe anæmia may play a part, probably in association with some degree of coronary atherosclerosis, for I have never seen a severe anæmia cause angina in a young subject, though this happens commonly in the more elderly. Alastair Hunter (1946), however, has described 12 cases of anæmic angina, of which 10 were in women, and 5 in persons aged 40 or less, the youngest being 31, which certainly suggests that anæmia alone may cause anginal pain.

Anginal pain is sometimes a symptom of rheumatic heart disease, but I have not included such cases in my series, because in my experience they do not conform to the clinical picture of the atherosclerotic type, though we know that rheumatic infection may produce somewhat similar coronary changes (Karsner and Bayless 1934). I have never seen a coronary occlusion complicating rheumatic heart disease, nor do I feel that anginal pain in a young rheumatic subject has the same serious significance as in the atherosclerotic patient.

We can conceive of the possibility of spasm of a healthy coronary artery producing a localised myocardial ischæmia with consequent coronary pain; but we have no proof that this does in fact ever happen, though we may suspect that an unstable vasomotor control may play a part in the clinical picture of the patient, familiar to us all, who suffers, perhaps for years, from anginal paroxysms of great severity, provoked by trivial physical effort, and especially by emotion. Findings on physical examination may be surprisingly negative; and consequently these patients are often regarded as cardiac neuropaths till at last the diagnosis of organic coronary disease becomes only too clear, perhaps as a result of the sudden and unexpected death of the patient.

Some years ago I used to diagnose " vasomotor angina " not infrequently in patients who complained of pain of typical distribution, this pain being provoked y effort, but especially by emotion, without physical of organic cardiovascular disease and with a normal electrocardiogram. Sometimes there was evidence of vasomotor instability, such as easy flushing, or Raynaud-like phenomena, or a history of migraine. But increasing experience has convinced me that sooner or later these patients present undoubted evidence of organic coronary disease. If the same amount of effort constantly provokes substernal pain or even discomfort, however slight, and if this discomfort disappears promptly with rest, I think we may assume with confidence some degree of coronary obstruction, however negative the findings may be.

As for that large heterogeneous group of so-called false angina, we can only speculate as to the explanation of their pain, feeling assured that it is not of coronary origin. Many of them are suffering from a cardiac anxiety state. There is an interesting, and sometimes a diagnostically difficult, group of patients, usually women, who have severe paroxysms of precordial, usually not sternal, pain, which may radiate into the arms, back, or jaws. These paroxysms may be provoked by emotion, or there may be no obvious exciting cause. They come after, rather than during, effort, and they are usually widely spaced, with periods of robust health, without limitation of physical effort, between them. The subjects of these attacks, though sometimes temperamental, are often quite stable psychologically. Their symptoms are very real and severe, and may indeed be alarming. Possibly these paroxysms may be due to spasm of the œsophagus or of the cardiac sphincter. Radiological confirmation of this is obviously difficult to obtain, though I understand that William Evans has made some interesting kymographic observations in this class of case. Diagnosis is made more difficult here by the fact that nitroglycerin gives relief; but perhaps it does so by relaxing gastric or œsophageal and not coronary spasm.

I submit that in the differential diagnosis betwe true angina and these non-coronary pains, careful history-taking is even more important than physical, including instrumental, examination, and that the *characteristic and constant* relationship between anginal pain and effort is fundamental.

ÆTIOLOGY

Sex-incidence.—Turning now to my own statistic out of 1000 patients, 779 were males, 221 females, givi a female-to-male ratio of 1 to 3·5, which seems to be abo the usual ratio found in the literature, though in recent report from the Mayo Clinic on 3440 angin patients the female-to-male ratio was 1 to 4·3 (Parker al. 1940). This far heavier incidence of angina on mal rather than on females has never, so far as I know received a satisfactory explanation. In the past n doubt women led a more sheltered life. But certainl

ABLE I—FREQUENCY DISTRIBUTION OF ELEVATION OF SERUM-PROTEIN LEVEL BY 15 MIN. WALKING, CALCULATED FROM SERUM SP. GR. AT 0 AND 60 MIN. AFTER EXERCISE

Serum-protein (g./100 ml.)	Below	Above resting level								Total cases	Elevation	
	0·18	0	0·18	0·36	0·54	0·72	0·90	1·08	1·26		Mean	S.D.
Recruits	6	12	29	31	23	6	4	—	1	112	0·33	0·2623
Trained soldiers ..	2	3	17	11	4	4	1	—	—	42	0·30	0·2375

The subjects belonged to a Madrasi Pioneer Battalion and were either recruits with less than a month's service or trained soldiers (mostly junior N.C.O.s) with over a year's service. The recruits' mean height was 63 in., S.D. 1·92 in., and mean weight 102 lb., S.D. 8·51 lb. The mean gain in weight of a recruit during six months' training is about 10 lb. All the men were aged 18–30, and most of them about 20.

METHOD OF INVESTIGATION

The men rose at dawn, 7 A.M., had a light breakfast of tea and chapattis (unleavened bread) at 7.30 A.M., walked to the laboratory, and rested until 8.30 A.M., when the experiment began.

Exercise consisted of either marching or pack test. For marching the men wore shirts, shorts, and chaplis (sandals). They marched on flat ground at the normal army pace for 15 min. For the pack test they wore shirts, shorts, and Army boots, and carried a third of their own weight in a pack. They mounted a 15-in. step (both feet up) thirty times a minute for 5 min., or for a shorter time until they were completely exhausted. They then sat down for $4^1/_2$ min. while the pulse-rate was counted. Few men took the full thirty steps a minute, but even so this was a most severe test. As each man completed his prescribed exercise he walked a few yards into the laboratory and squatted on the floor (sepoys are not comfortable on chairs). He remained in the same place until the observations were completed.

Venepuncture.—Blood was taken from an arm vein with a syringe sterilised with hot liquid paraffin. No tourniquet was used, but if necessary the veins were made prominent by the pressure of a hand not exceeding 10 sec. Blood for serum (3 ml.) was allowed to clot in a sloped position; the serum was withdrawn and its sp. gr. determined after 4–6 hours. Blood for hæmoglobin and hæmatocrit determinations (2·5 ml.) was mixed with Wintrobe's dry anticoagulant (Whitby and Britton 1942), and the hæmoglobin pipette and hæmatocrit were immediately filled before sedimentation began.

Specific Gravity of Serum.—This was determined by Van Slyke's copper-sulphate method (Phillips et al. 1945). The stock solution was made by dissolving 170 g. of $CuSO_4.5H_2O$ in 1002·4 g. of water, and the standard solutions were made by dilution of this stock. The sp. gr. of the stock solution and of a standard solution (usually 1028) were checked by weighing.

For the sake of clarity in our calculations and tables we use the notation 1000 (not 1·0) for the sp. gr. of water. Our standard solutions were 1 unit apart in this notation—i.e., 1020, 1021, &c.—and we estimated the sp. gr. of the serum to the nearest 0·5.

We renewed a standard solution when about a fiftieth of its volume of serum had been added. According to Phillips et al. (1945) the sp. gr. of the solution at this time would be decreased by about 0·4; hence the mean sp. gr. of our solutions during their life was about 0·2 below their initial value. We have made no allowance for this rather variable error in the sp. gr. figures given in this paper.

In calculating mean serum-protein levels we have tried to allow for the degradation of our solutions by using a modification of van Slyke's formula:

$$\text{Serum-protein} = (\text{serum sp. gr.} - 1007{\cdot}2) \times 0{\cdot}36.$$

Hæmoglobinometry.—Blood 0·02 ml. was mixed in N/10 HCl 0·4 ml., allowed to stand for 80 min., diluted to 1·59 ml. with distilled water, and matched against the glass wedge of the Zeiss hæmometer. The standardisation of this instrument has been described elsewhere (Hynes et al. 1945, 1946). The standard error of a single reading is ±0·16 g. of hæmoglobin. When two hæmoglobin determinations were made on the same person, the same pipette and dilution tube were used on each occasion, and the same worker matched the colour without reference to the previous reading.

Packed Cell Volume.—The blood was spun for 45 min. at 3000 rev./min. in Wintrobe hæmatocrits. The same tube was used for both determinations on each person.

RESULTS OF EXERCISE

Marching.—Both in recruits and in trained soldiers, marching for 15 min. raised the mean serum-protein level (calculated from the serum sp. gr.) about 0·3 g. above the resting level. The course of the return to normal is shown in fig. 1. The recovery was 75% complete after 15 min. rest and complete after 30 min.

The statistical significance of these findings was tested by analysis of the variance of the serum sp. gr. figures between times and between persons (Fisher 1942, 1944). From the residual mean square we calculated the standard error of the difference between means and then tested the significance of these differences by the t test. Both in recruits and in trained soldiers the mean serum sp. gr. after 0, 15, and 30 min. rest differed very significantly from one another (P less than 0·001), but there was no significant change after 30 min.

There was a wide variation between individuals in the degree of elevation of the serum-protein level after marching (table I). The mean elevation in recruits was not significantly higher than in trained soldiers (t : 0·636, P : 0·5).

Pack Test.—We first determined the serum sp. gr. when the men had sat down for 30 min. before the test, and then after the test at intervals from 5 to 95 min. This violent exertion caused an elevation of the serum-protein level twice as great as did gentle exercise (marching), and the return to normal took twice as long (fig. 1). The recovery curve followed the same pattern both in recruits and in trained soldiers—after 20 min. rest the serum-protein level had fallen half-way towards its resting level; after 35 min. recovery was 85% complete; and the resting level was reached in an hour.

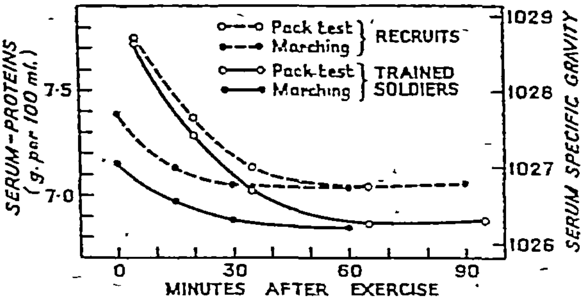

Fig. 1—Return of serum-protein level to normal on rest after exercise.

Statistical analysis showed that the mean serum sp. gr. 5, 20, 35, and 65 min. after the exercise differed very significantly, but there was no significant difference between the means after 65 and 95 min. rest, nor did these differ significantly from the mean resting sp. gr. before the exercise.

There was wide variation between individuals in the degree of elevation of the serum-protein level by the pack test (table II). The mean elevation was 20% greater in trained soldiers than in recruits, and the difference was definitely significant (t : 2·777, P : 0·01, area deprived of blood supply will be much greater than that following blockage of a similar vessel in a normal circulation."

Hence, presumably, the sudden fatal attacks in Hume's coalminers with previously symptomless fibrotic hearts. In this way too we find an explanation for the fact that, on the whole, angina in those aged over 70 runs a more benign course than it does in those aged under 50.

RELATION TO HYPERTENSION

Investigating the relationship between hypertension and coronary disease, I classified my cases as having a normal blood-pressure where the readings were below 160/100, moderate hypertension above these figures but below 200/120, and gross hypertension above 200/120. Throughout the entire series, in 44·6% the pressure was normal, in 33·7% moderately, and in 21·7% grossly increased. Excluding those cases in which an existing or recent coronary occlusion was thought to be responsible for a low blood-pressure, the figures were normal tension 30·6%, moderate hypertension 42·3%, gross hypertension 27·1%. So nearly 70% of my anginal patients without coincident or recent coronary occlusion were hypertensives. These findings surprised me, for I had not realised that the proportion of hypertensives was so high.

Fisher and Zukerman (1946) say that, in the literature, hypertension antedating coronary occlusion has varied between 33% and 73%. Of their own 108 cases of coronary occlusion, hypertension antedated the occlusion in 65% of the women and 39% of the men. They point out that negroes, though more liable than whites to hypertension, show a significantly lower incidence of coronary disease. Nevertheless, one cannot help suspecting that there may be some ætiological factor in common between hypertension and coronary disease. But unhappily, in spite of all the intensive investigation of hypertension during the last decade, fruitful though it has been, we are still abysmally ignorant of its ætiology —in the words of Harvey, "all we know is infinitely less than all that still remains unknown." Is it possible that in the remarkable sex-incidence of coronary disease we may find some clue to ætiology? Can it be that masculinity predisposes one to coronary disease, and that femininity safeguards from it—that perhaps cholesterol metabolism is vitiated by maleness? In this connexion it is interesting to note that some maintain that it is the more masculine type of woman who is prone to develop coronary disease—though I confess that this has not been my experience.

ENVOI

During the past few months I have often asked myself how Harvey would have approached the problem which I have here so lamentably failed to solve. Certainly not by speculations, nor by clinical impressions; and I very much doubt whether the statistical approach would have made much appeal to him. He would have agreed with Fernel that "We cannot be said to know a thing of which we do not know the cause" (Sherrington 1946). When asked *why* the blood circulated, he replied that he could not say. Harvey was interested only in proving by experiment that it did circulate: "it is shown by the application of a ligature that the passage of the blood is from the arteries into the veins" (Harvey 1616). I hope that today he would have accepted coronary arterial disease as the cause of angina, and I believe that he would be one of the many workers who are endeavouring "to search and study out the secrets" of hypertension and of arterial disease by experiment, whether in the laboratory or at the bedside.

In conclusion I recall the indenture of Harvey, dated June 26, 1656, in which he conveyed to the college the gift of his patrimonial estate of Burmarsh, in Kent. He exhorted the fellows and members to search and study out the secrets of nature by way of experiment; and also for the honour of the profession, "to continue mutual love and affection amongst themselves, witho which neither the dignity of the college can be preserv nor yet particular men receive that benefit by th admission into the college which else they might expe ever remembering that *Concordia res parvæ crescu discordia magnæ dilabuntur.*"

Never before was it more vital to the college, to th profession, and to the State, that these exhortations Harvey should be faithfully obeyed.

SERUM-PROTEIN LEVEL OF INDIAN SOLDIERS

MARTIN HYNES
M.D. Camb., M.R.C.P.
MAJOR R.A.M.C.

MOHAMMED ISHAQ
L.S.M.F.
CAPTAIN I.A.M.C.

T. L. MORRIS
SERGEANT R.A.M.C.

From the Anæmia Investigation Team, General Headquarters, India

It is now generally accepted that the specific gravity of the serum, estimated by Van Slyke's copper-sulphate method, is a reasonably accurate measure of the serum-protein level. We used the method as part of a nutritional and hæmatological survey of Indian Army recruits (Hynes et al. 1946), but our results were so at variance with expectation that we could not be satisfied of their validity without a more detailed investigation, which is reported here. The work was done deep in the jungle with very limited laboratory facilities, and it is a fair criticism that it raises more problems than it solves.

If it is accepted that the sp. gr. of the serum of our subjects bears the usual relation to the serum-protein level, then we have shown that the recruit, fresh from a life of extreme poverty on a grossly protein-deficient diet, has a serum-protein level higher than that of the trained soldier. We found also that the effect of exercise on the sp. gr. of the serum was considerably greater than we had anticipated from the literature, but we present data to show that this effect can be avoided by simple precautions.

This work was done in Harihar, Mysore State, 1700 ft. above sea-level, during August, September, and October, 1945. The weather was cool but rather humid, with early-morning temperatures of about 75° F, and a maximum not exceeding 90° F.

a substantial volume of red cells were abstracted from the circulation during the hour after the pack test.

THE RESTING SERUM SPECIFIC GRAVITY

Table VI shows the frequency distribution of the resting serum sp. gr. in recruits, trained soldiers, and a few young European men who had been in the station for at least three months. Fig. 2 shows the Indians' distribution in terms of serum-protein. There was no significant difference between the mean serum sp. gr. of the Europeans and the trained Indian soldiers (t : 0·460, P : 0·65), but the recruits' mean was very significantly above that of trained soldiers (t : 3·994) and significantly above that of Europeans (t : 2·348, P : 0·02).

TABLE VI—FREQUENCY DISTRIBUTION OF RESTING SERUM SP. GR. IN INDIAN RECRUITS AND TRAINED SOLDIERS AND IN EUROPEANS

Serum sp. gr.	1023	1023·5	1024	1024·5	1025	1025·5	1026	1026·5	1027	1027·5	1028	1028·5	1029	1029·5	No. of cases	Mean	S.D.
Recruits ..	2	—	1	3	7	14	29	31	29	21	11	9	9	5	171	1026·81	1·2213
Trained soldiers	—	—	—	1	8	10	27	23	14	6	—	1	—	—	90	1026·25	0·7238
Europeans ..	—	—	—	1	1	5	5	4	3	1	1	—	—	—	21	1026·17	0·8416

The mean hæmoglobin in the 171 recruits was 14·67 g., S.D. 1·424, range 9–17 g.; in 90 trained soldiers 16·31 g., S.D. 0·9073, range 13–19 g.; and in 21 Europeans 15·85 g., S.D. 0·7048, range 14–17 g. In none of these groups was there any suggestion of a correlation between the hæmoglobin level and serum sp. gr. If blood is taken from incompletely rested subjects, a spurious correlation between the hæmoglobin and serum-protein levels must be created. Each hæmoglobin group will contain a proportion of men who on further rest would fall back into lower hæmoglobin and serum-protein groups. The highest hæmoglobin group is always numerically the smallest; hence it will contain a high proportion of subjects who, if their hæmoglobin and serum-proteins had reached the resting levels, would be in the larger penultimate hæmoglobin group. The highest hæmoglobin group as observed will therefore have an artificially high serum-protein level. It is easy to see that this will apply to all classes on the descending part of the hæmoglobin frequency distribution curve; and by the reverse process groups on the ascending part of the curve will be given an artificially low serum-protein level.

We have shown elsewhere (Hynes et al. 1946) that in these recruits there was a clear correlation between malnutrition, as assessed clinically, and the hæmoglobin level, but we found no similar correlation between nutrition and serum sp. gr.

DISCUSSION

The Medical Research Council (1945) has emphasised the importance of taking blood for serum-protein estimations after a strictly standardised period of rest. Our figures re-emphasise the necessity of this precaution not only for serum-protein estimations but also for other blood investigations. The very moderate exertion of walking a mile raises the average serum-protein level 0·3 g. per 100 ml., and the increase is often three times as great. When the subject sits down, the protein level falls within 30 min. to a stable resting level; three-quarters of this fall takes place in the first 15 min.

Very violent exertion for 5 min. raises the average serum-protein level 0·75 g., and an increase twice as great is not uncommon. After 20 min. rest the serum-protein level has fallen only half-way towards its resting level, and after 35 min. only 85%. The resting level is reached in an hour.

Vaughan (1945) has suggested that these variations are greater in untrained persons. We found no difference between recruits and trained soldiers in the elevation of the serum-protein level after gentle exercise, and after violent exertion the trained men showed the greater change. They had, however, worked harder.

The raised serum-protein level is largely due to a diminution in the plasma volume on exertion, and the other blood constituents naturally reflect this change. The average hæmoglobin level after walking a mile is 0·4 g. per 100 ml. (3% Haldane) above the resting level, and differences exceeding 1 g. (7% Haldane) are often seen. The average P.C.V. is 1% higher, and in individual cases often 2% higher. After violent exertion the mean increase in the hæmoglobin level is 0·9 g. (6% Haldane), and the increase may exceed 1·5 g. (10% Haldane). The mean rise in the P.C.V. is 4%, and an increase of 6% is not uncommon.

It is recognised (Medical Research Council 1945) that there is an appreciable increase in the volume of the red cell as the blood passes from the arterial to the venous state. Our data show that a person's activity affects the size of his venous red cells, presumably in an analogous fashion. We calculated that the red cell was very slightly smaller after walking a mile than after sitting down for 90 min.—presumably in walking an increased venous return without an appreciable increase in oxygen consumption increases the oxygenation of venous blood. On the other hand, the cells of men still in oxygen debt from violent exertion were some 2·5% larger than in the resting state.

We have shown that our data are compatible with the hypothesis that the increase in plasma volume on rest after gentle exercise is due simply to the addition of protein-free fluid to the circulating blood. After violent exertion, however, a more complex change must take place; besides an increase in plasma volume and a contraction of the red cells, either protein must pass into the circulation or red cells must be abstracted from it.

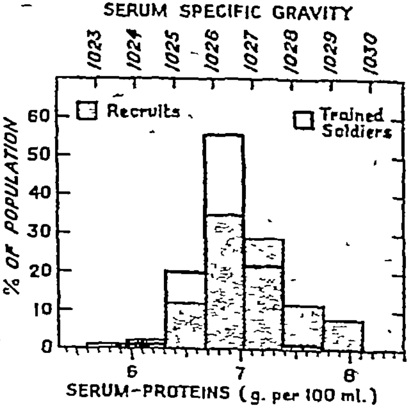

Fig. 2—Frequency distribution of serum-protein level in Indian recruits and trained soldiers.

Since hypoproteinæmia is a feature of famine starvation, it has been supposed that less absolute degrees of dietary protein deficiency will be reflected in the serum-protein level. Verma (1946) has shown that the civilian diet of our recruits was grossly deficient in animal protein and low in vegetable protein, yet we found that their serum sp. gr., and presumably serum-protein level, was definitely higher than that of trained soldiers of the same race. We could correlate anæmia, but not the serum sp. gr., with the degree of malnutrition. It does not necessarily follow that this was true before the recruits left their villages. When we examined them, they had enjoyed the Army ration (animal protein 20 g., vegetable protein 100 g. daily) for 1–4 weeks, and it is possible that this unaccustomed protein richness had raised their serum-protein from an abnormally low to an abnormally high level. Alternatively a change

TABLE II—FREQUENCY DISTRIBUTION OF ELEVATION OF SERUM-PROTEIN LEVEL BY VIOLENT EXERTION, CALCULATED FROM SERUM SP. GR. AT 5 AND 65 MIN. AFTER PACK TEST

Serum-protein (g./100 ml.)	Above resting level										No. of cases	Elevation	
	0·18	0·36	0·54	0·72	0·90	1·08	1·26	1·44	1·62	1·80		Mean	S.D.
Recruits	2	6	12	19	11	2	1	—	—	1	54	0·70	0·2678
Trained soldiers ..	1	2	7	10	14	10	2	2	—	—	48	0·85	0·2640

(In tables I and II, 1 sp. gr. unit is taken as equivalent to 0·36 g. of serum-protein per 100 ml.)

from the serum sp. gr. figures). It is impossible to assess the meaning of this difference, for the trained soldiers were better disciplined than the recruits and undoubtedly worked harder at the pack test.

The change in serum sp. gr. bore no relation to the pack-test score, which is supposed to measure physical efficiency, but our subjects coöperated in the test so badly that we place little reliance on the scores.

Concomitant Measurements.—We measured the serum sp. gr., hæmoglobin, and packed cell volume (P.C.V.) immediately after exercise and 90 min. later after rest in 67 recruits after marching and in 30 trained soldiers after the pack test. The results are shown in table III.

TABLE III—EFFECT OF EXERCISE ON MEAN SERUM SP. GR., SERUM-PROTEIN LEVEL (G./100 ML.), PACKED CELL VOLUME (P.C.V.), HÆMOGLOBIN (G./100 ML.), AND MEAN CORPUSCULAR HÆMOGLOBIN CONCENTRATION (M.C.H.C.)

—		Serum sp. gr.	Serum-protein	P.C.V.	Hæmoglobin	M.C.H.C.
67 recruits	Marching	1027·91	7·46	43·55	14·75	33·98
	At rest ..	1027·12	7·17	42·74	14·39	33·78
30 trained soldiers	Pack test	1028·87	7·80	52·52	17·47	33·28
	At rest ..	1026·57	6·97	48·55	16·58	34·15

Values obtained at 0 and 90 min. after marching and 5 and 95 min. after pack test.

After marching, the hæmoglobin and P.C.V. increases were of the same degree as the elevation of the serum-protein level; *the range of the changes is shown in* tables IV and V. The resting mean corpuscular hæmoglobin concentration (M.C.H.C.) was slightly lower than the working value, and the mean difference, 0·197%, S.D. 0·6764, was significantly different from zero (t : 2·384, P : 0·02). The suggestion is that the red cell is a little larger at rest than during gentle exercise, but so slight a change might well be extraneous rather than physiological.

After violent exercise the changes in hæmoglobin and P.C.V. were much greater (tables II, IV, V). The average increase in hæmoglobin was 0·9 g. (range 0–1·6 g.), and the average P.C.V. increase was 4% (range 2–6%). The working M.C.H.C. was considerably below the resting value, and the mean difference, 0·873%, S.D. 0·7182, differed very significantly from zero. The working mean corpuscular volume must therefore have been about 2·5% above the resting volume.

If we assume that the return of the serum-protein level to the resting level after exercise is effected solely by the addition of protein-free fluid to the circulating plasma, then the resting plasma volume must be:

$$\frac{P}{P'}\ B(100-H) \quad \cdots \quad \cdots \quad \cdots \quad \cdots \quad (1)$$

where B, H, and P are the working blood-volume, P.C.V., and serum-protein level respectively, and P′ is the resting serum-protein level. If we neglect the slight expansion of the red cells after gentle exercise demonstrated above and assume the circulating red-cell volume to remain unchanged at B.H, then the new P.C.V., H′, should be given by the equation:

$$H' = \frac{100.\ B.H}{B.H+P(100-H).B/P'} = \frac{100.\ H.P'}{100P-H(P-P')} \quad \cdots (2)$$

Such an equation, containing three estimations subject to experimental error, must be very inaccurate; but, if our hypothesis is true, it should give an equal number *of positive and negative errors.* We calculated the equation for our 67 results after marching and found that the mean difference (observed−calculated value) was +0·124, which was less than its standard error of ±0·1259. Our results are therefore consistent with the hypothesis that the return of the serum-protein level after gentle exercise to the resting level is due simply to the addition of protein-free fluid to the circulating plasma. (It should be noted that we have not proved this hypothesis, we have merely failed to disprove it.)

The pronounced change in mean corpuscular volume after the pack test necessitates a more complicated calculation. If we assume that after the pack test no *red cells went out of circulation, then the resting* blood-volume would be given by $B\ \frac{Hb}{Hb'}$, where B is the working blood-volume, and Hb, Hb′ are the working and resting hæmoglobin levels respectively. The equation (1) derived above for the plasma volume may therefore be equated to:

$$\frac{P}{P'}\ B(100-H) = \frac{Hb}{Hb'}\ B(100-H')$$

or

$$Hb' = \frac{100-H'}{100-H} \cdot \frac{P'}{P}\ Hb \quad \cdots \quad \cdots \quad \cdots \quad (3)$$

This equation contains five estimations subject t experimental error; but again, if our hypothesis i *true, it should give an equal number of* positive an negative errors. We calculated the equation for the 3 results after the pack test and found the mean differenc (calculated−observed value) to be +0·393, S.D. 0·5741 So great a difference from zero would not occur on time in a thousand by chance (t : 3·783), so we mus conclude that our hypothesis is wrong. The discrepanc would be explained either if the new fluid added to th circulating plasma had a small protein content, or i

TABLE IV—FREQUENCY OF DISTRIBUTION OF ELEVATION O HÆMOGLOBIN LEVEL BY EXERCISE

Hæmoglobin (g./100 ml.)	Below	Above resting level				No. of cases	Elevation

Pack test ..	—	4	14	8	4	30	0·89	0·4185

Calculated from the figures immediately and 90 min. after exercis

TABLE V—FREQUENCY OF DISTRIBUTION OF ELEVATION O PACKED CELL VOLUME BY EXERCISE

P.C.V. (%)	Below	Above resting level							No. of cases	Elevation	
	1–	0–	1–	2–	3–	4–	5–	6–		Mean	S.D.
Marching ..	13	26	19	9	—	—	—	—	67	0·81	0·9573
Pack test ..	—	—	—	7	9	6	6	2	30	3·97	1·2313

Calculated from the figures immediately and 90 min. after exercise f micturition, and thought his urine had been slightly red or two or three days. He noticed puffiness of the eyelids three days before admission.

His past history had been uneventful, except for a slight sore throat after bathing in the Thames twenty-one days before. This cleared up in a few days, and he had again bathed in the Thames twelve days before entering hospital. No-one else in the family had been ill recently.

He was a well-developed intelligent boy, looking acutely but not seriously ill. Temperature 102° F, pulse-rate 108, respirations 22 per min. There was slight but definite puffiness of the eyelids, chiefly of the upper lids, but no peripheral œdema. Skin hot and dry, breath fœtid, tongue furred, and mild marginal gingivitis. Throat slightly injected. No abnormal physical signs in heart and lungs. Liver, spleen, and kidneys not palpable. Except for a suggestion of neck-rigidity, examination of the central nervous system revealed nothing unusual. Urine contained visible blood and much albumin, with numerous cellular and granular casts but no organisms. Blood-urea 37 mg. per 100 c.cm. Blood-pressure 120/60 mm. Hg. A tentative diagnosis of acute glomerulonephritis was made.

Next morning the boy seemed better, and his temperature had fallen to 100° F, but it rose during the night to 104° F and then fell to normal. Throat-swab culture was negative for hæmolytic streptococci, but a white-cell count showed 8900 cells per c.mm. with polymorphs 73%, lymphocytes 20%, and monocytes 7%.

On the 14th his temperature again rose to 101·8° F and he still complained of headache. Photophobia was well marked, but there was no conjunctivitis. Neck-stiffness was more evident, and slight blurring of the optic disk was seen on examination of the fundi. A lumbar puncture was performed, and turbid C.S.F. under raised pressure was obtained; this contained 690 cells per c.mm. (lymphocytes 70%, polymorphs 30%) but was sterile on culture; chlorides were 690 mg. per 100 c.cm., and an excess of globulin was present.

Leptospirosis was suspected by this time, so penicillin therapy was begun the same day, 10,000 units being given intrathecally, followed by the same dose intramuscularly, the latter being repeated every three hours. In twelve hours the boy seemed perfectly well, his temperature was normal, urinary abnormalities had disappeared, and he made a dramatically swift recovery. Penicillin treatment was discontinued on the 17th, after 22 doses (220,000 units) had been given. On that day, however, the C.S.F. was still turbid and contained 300 white cells per c.mm., with lymphocytes predominating but no excess of globulin. Chlorides were 740 mg. per 100 c.cm. Culture was again sterile. Confirmation had been received from the hospital laboratory of the presence of antibodies to *L. icterohæmorrhagiæ* in a specimen of blood taken on Sept. 18, but the peculiar features of the case suggested the desirability of a more extensive investigation than was possible locally. This later investigation is described below.

TABLE I—DIRECT RESULTS OF SEROLOGICAL TESTS

Strain	Type	Titre of serum obtained on		
		Sept. 22	Oct. 15	Nov. 24
Wijnberg ..	*L. ictero-hæmorrhagiæ* AB	300	100	100
McIntyre ..	*L. ictero-hæmorrhagiæ* B	1000	300	300
Utrecht IV	*L. canicola*	10,000	10,000	3000
Berlin 4129	*L. canicola*	10,000	30,000	10,000
L.5260 ..	..	30	30	..
Moscow V. ..	*L. grippo-typhosa*	0	..	..
..	*L. pomona* ..	0	..	..
..	*L. sejroe* ..	100	100	30
..	*L. autumnalis A*	0	..	..
..	*L. autumnalis B*	0	..	..
..	*L. bataviæ* ..	0	..	..

The patient was discharged from hospital on Oct. 1 quite well and remained free from symptoms till Nov. 15, when he was readmitted with a history of slight hæmaturia. His main complaint was headache, but his C.S.F. showed no increase in cells or protein; his urine, however, contained numerous red blood cells. In hospital he had no symptoms, and in two days his urine was normal, his blood-urea 41 mg. per 100 c.cm., and a urea-concentration test gave normal results. Blood-pressure was not raised. Before his discharge on Dec. 1 a further sample of blood was obtained for serological tests.

Serological Investigation.—Serological tests were carried out according to Schüffner's method as described by Davidson et al. (1934). Both living and formolised culture antigens were used in parallel tests, but the results were practically identical. The strains of leptospira used were "Wijnberg," a typical "complete" strain of *L. icterohæmorrhagiæ* (Gispen and Schüffner 1939); "McIntyre," an incomplete strain (proved by reciprocal agglutination to be identical with strains "Hickey" and "Wien I"); "Utrecht IV," a typical strain of *L. canicola* used by Prof. W. Schüffner; and "Berlin 4129," another strain of *L. canicola*, obtained from Professor Schlossberger. "L.5260" was provided by Prof. A. D. Gardner, and most of the other strains by Dr. Lépine, of the Pasteur Institute. Absorption tests were carried out according to the technique followed by Buckland and Stuart (1945). Table I shows the results of the direct tests on the patient's sera, and table II the necessary absorption tests. Titres are given as the reciprocal of the dilutions in each case.

TABLE II—ABSORPTION TESTS ON SERUM TAKEN SEPT. 22

Titre with	Unabsorbed	Absorbed with	
		L. ictero-hæmorrhagiæ B	*L. canicola*
L. ictero. AB ..	300	0	0
L. ictero. B ..	1000	30	30
L. canicola ..	10,000	3000	0
L. sejroe ..	100	..	0

The titres with both strains of *L. canicola* were higher than the corresponding titres with strains of *L. icterohæmorrhagiæ*, and the former tended to rise and the latter to fall as the disease progressed. The *L. canicola* antibodies are shown to be specific by the absorption test, where *L. canicola* removes both homologous and heterologous antibodies from the serum, whereas a *L. icterohæmorrhagiæ* strain leaves the *L. canicola* antibodies practically intact.

DISCUSSION

Since this is claimed to be the first case of *L. canicola* infection discovered in Britain, it is unfortunate that an opportunity did not arise to isolate the organism from the patient, but on serological grounds the evidence is quite definite. Para-specific serum titres to *L. canicola*, sometimes greater than to *L. icterohæmorrhagiæ*, have been encountered occasionally by one of us (R. D. S.) in the early stages of Weil's disease and have been recorded by Gispen and Schüffner (1939). Such reactions are reputedly associated mainly with infections caused by the "incomplete" B type of *L. icterohæmorrhagiæ*, though there is no evidence that this type has any greater antigenic similarity to *L. canicola* than the usual AB type. Petersen (1938) made the observation that within the classical type of *L. icterohæmorrhagiæ* was a subtype which lacked an antigenic factor present in the others. Subsequently this "incomplete" subtype was represented by the letter B, while the "complete" strains were indicated by the letters AB. There is apparently no clinical difference in the diseases caused by these respective strains, but the serological investigation of cases is often helped considerably by an appreciation of these antigenic variations. In Weil's disease the para-specific serum reactions to *L. canicola* invariably decline as the disease progresses, and the specific antibody response becomes dominant; they are also readily removed by absorption with a *L. canicola* culture, which has little or no effect on the specific antibody. Absorption of such a serum, however, with a *L. icterohæmorrhagiæ* culture removes both specific and para-specific antibodies. In the present case the dominance of *L. canicola* antibodies throughout the illness, their resistance to absorption with *L. icterohæmorrhagiæ*, and the almost complete absorption of both *L. icterohæmorrhagiæ* and *L. canicola* antibodies with *L. canicola*, leave no doubt that in this instance *L. canicola* was the infecting strain.

The manner of infection can only be surmised. The boy did not possess a dog, nor did he play with dogs.

in the level of some other blood constituent—e.g., cholesterol—may have been responsible for the increased serum sp. gr. On either hypothesis, with custom would come tolerance to protein and a fall of the serum sp. gr. to normal.

We may conclude by re-emphasising the importance of strictly standardised conditions in any hæmatological survey. The change in the plasma volume after exercise not only depends on the amount of exercise, but also there are wide individual variations in the response to a given amount of exercise. A stable value is only reached after $^{1}/_{2}$–1 hour's rest, and it is essential that the subject should rest for this period before he is bled, and be bled where he has rested. The variations seen after a less complete period of rest may be unimportant in the individual case, but they are large enough to introduce serious errors into the statistical analysis of even moderately large series.

It remains an open question whether the serum-protein level may be taken as an index of the protein adequacy of the diet. Certainly we have shown that the serum sp. gr. is above rather than below the normal level in men who after a lifetime of protein semi-starvation have eaten a good diet for two or three weeks. It is to be hoped that this problem will be further investigated with the aid of the biochemical methods which were not at our disposal in the jungle during this investigation.

SUMMARY

We estimated the serum-protein level of Indian recruits and trained soldiers by the copper-sulphate serum sp. gr. method.

Gentle exercise caused average increases of 0·3 g. per 100 ml. in the serum-protein level, 0·4 g. per 100 ml. in the hæmoglobin level, and 1% in the packed cell volume (P.C.V.). The increases were sometimes three times as great as this.

These blood values returned to their resting level after 30 min. rest. This change may have been due simply to the addition of protein-free fluid to the circulating blood.

Violent exertion caused average increases of 0·75 g. per 100 ml. in the serum-protein level, 0·9 g. per 100 ml. in the hæmoglobin level, and 4% in the P.C.V. The increases were sometimes twice as great as this.

The resting levels were again reached after an hour's rest. This change was largely due to an increase in the plasma volume, but also the red cells contracted, and either protein passed into the circulation or red cells were abstracted from it.

Our findings re-emphasise the importance, in any large-scale hæmatological survey, of taking blood after an adequate and strictly standardised period of rest.

There was no difference between the resting serum sp. gr. of trained Indian soldiers and Europeans, but the resting serum sp. gr. of newly joined Indian recruits was significantly higher than that of either. Possible explanations are briefly discussed.

Our thanks are due to the D.M.S. in India for permission to publish this paper; Prof. E. J. King for his very helpful advice and criticism; Mr. C. K. Dilwali, statistical officer (research), General Headquarters, India, for advice on statistical methods; and Lieut.-Colonel G. M. Holland, commanding no. 3 Training Battalion, I.P.C., and his officers for their help and coöperation.

LEPTOSPIROSIS CANICOLA

A CASE TREATED WITH PENICILLIN

M. D. BABER
M.D. Lond., M.R.C.P.
PHYSICIAN, ST. HELIER HOSPITAL, CARSHALTON, SURREY

R. D. STUART
M.D., D.Sc. Aberd., D.P
CITY BACTERIOLOGIST
GLASGOW

Leptospira canicola is morphologically and cultura similar to *Leptospira icterohæmorrhagiæ*, from which i can be distinguished by serological tests and by t fact that it is carried and transmitted solely by do (Walch-Sorgdrager and Schüffner 1938). In the do *L. canicola* produces a variety of symptoms, from trivial to severe, but generally referable more to kidney damage than to liver involvement (Dhont et al. 1934). The various forms of nephritis, particularly that variety recognised clinically as Stuttgart disease, are common, and jaundice is rare. After recovery the animal is liable to become a carrier, though usually for a few months only (Klarenbeek and Voet 1933). Leptospiræ are then found lying in masses within the lumina of the kidney tubules, in exactly the same situation as *L. icterohæmorrhagiæ* are found in the rat, and are excreted similarly in the urine. *L. canicola* is highly infectious to dogs, but its pathogenicity is much less than that of *L. icterohæmorrhagiæ*, and its invasive power in other animals, such as guineapigs, is very much less. This may explain why the number of human infections recorded has been so small.

The first instance of human disease was identified in Holland by Dhont et al. (1934), and by 1941 Raven noted that 22 such infections had been discovered: 12 in Holland, 1 in Austria, 7 in Denmark, and 2 in California Since that time 2 cases have been claimed by Bruno et al. (1943), and another by Tievsky and Schaefer (1944), all in the U.S.A. The first case in Norway has lately been recorded by Aalvik (1946). Other cases may have been reported in journals inaccessible during the war, but the incidence is unlikely to be high. Tiffany and Martorana (1942) investigated sera from 1351 persons in New York City without finding any positive to *L. canicola*.

In Britain no disease directly ascribable to *L. canicola* has so far been recorded. Stuart (1938) found low-titre agglutinins to this organism (proved to be specific by absorption tests) in the serum of a woman tripe-scraper, aged 43, who gave no history of illness. The dog-transmitted leptospiral disease recorded by Gardner (1943) was ascribed by him to a serologically distinct organism, *L. icterohæmorrhagiæ* 5260.

SYMPTOMS OF LEPTOSPIROSIS CANICOLA IN MAN

Walch-Sorgdrager (1939) discussed the largest series of human cases so far recorded. She pointed out that clinically the disease was very variable in signs and symptoms; jaundice, however, was rare, and mortality nil. The typical syndrome produced by *L. canicola* in the dog—the serious kidney disorder leading to uræmia—was not found in man, though albuminuria, with leucocytes, red blood cells, and casts in the urine, was often present for a few days. On the other hand, the frequency of meningitis or meningismus was notable ("in 4 out of 12 patients"). The cerebrospinal fluid (C.S.F.) was hazy or frankly purulent, usually with polymorphs predominant. In general, patients exhibited symptoms like those of influenza with an acute onset, fever, headache, shivering, and muscular pains. Convalescence was often protracted but occasionally dramatically brief. Our patient showed many of these features.

CASE-RECORD

A boy, aged 11 years, previously healthy, was admitted t hospital on Sept. 10, 1945, with hæmaturia, malaise, headache, and pains in the calves for two days. He felt nauseate but had not vomited. He admitted to moderate frequency

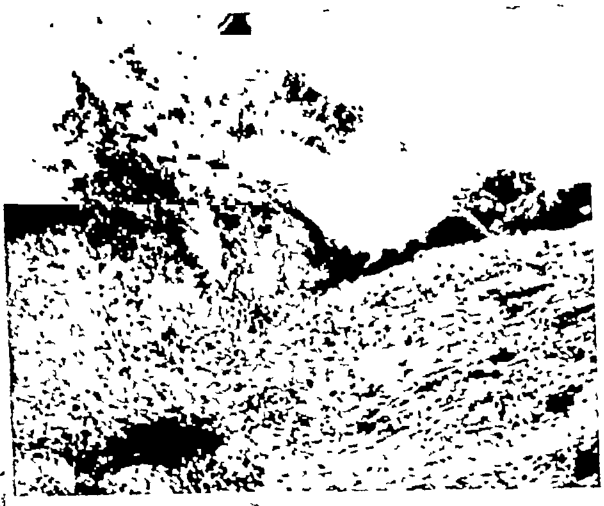

Fig. 2—Photomicrograph of section of ulcerated inferior turbinate bone. Note demarcation between necrosis and slough on the left and myxomatous connective tissue, with its colonies of fibroblasts and capillaries on the right. (×90.)

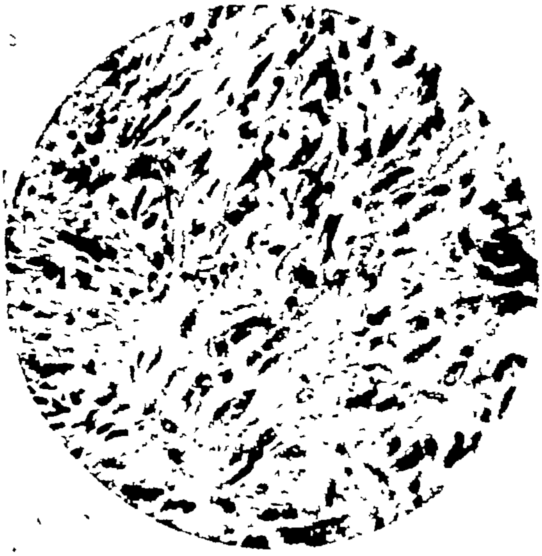

Fig. 4—Photomicrograph of cellular granulation tissue. (×320.)

Opinion seems to be more or less equally divided between describing the condition as an infective granuloma of uncertain ætiology and attributing the changes to a tumour growth.

All forms of treatment have been tried, from chemical cautery and surgical excision to radium implantation and X rays. Woods's (1921) second case was healed by radium needles placed in dental wax upon the ulcer-perforation. McArthur's (1925) case derived no benefit from radium, but showed satisfactory healing after three full doses of X-ray therapy. All other reported cases have been resistant to any form of treatment, and death has usually resulted from a vague cachexia or toxæmia coupled with repeated blood-loss from the lesion.

CASE-RECORD

A farmer, aged 58, was first seen by his doctor in May, 1945, with a history of a neuralgic pain involving the distribution of the second division of the 5th nerve. The teeth were carious, and it was thought that the neuralgia was due to sepsis in the upper jaw. He did not take his doctor's advice to have dental treatment. The first upper right premolar, canine, and lateral incisor teeth fell out during the next four weeks, followed by ulceration and necrosis of the adjacent alveolar margin. The ulceration spread along the premaxillary region of the hard palate, destroying the mucosa. This was followed by a sloughing and necrosis of the bone, with formation of a fœtid sinus opening into the floor of the nose.

On August 29, 1945, the patient was seen at the Royal Salop Infirmary, when a hole 1 in. in diameter was found in the premaxillary region of the palate and the alveolar margin. There was also a tender red swelling over the anterior wall of the maxilla. A tentative diagnosis of syphilis was made, but the Wassermann reaction was negative. The patient was told to report in a week but did not, and was sent for on Sept. 17.

On the 19th the patient was seen again as an outpatient. He was cachectic from toxic absorption, with a very pale face, and had a temperature of 100° F. He talked with a nasal voice. The anterior end of the inferior turbinate was covered with a dirty greyish slough blocking the right nasal passage. The lateral wall of the nose beneath the inferior turbinate was eroded, and the whole of the anterior half of the floor of the nose was absent. Necrosis also involved the floor of the antrum. The septum was intact, and the disease was limited to the right nasal cavity. The middle turbinate was not involved.

After the sloughs had been removed from the nose the posterior third of the inferior turbinate was seen to be intact. This was seen with a nasopharyngoscope, it being impossible

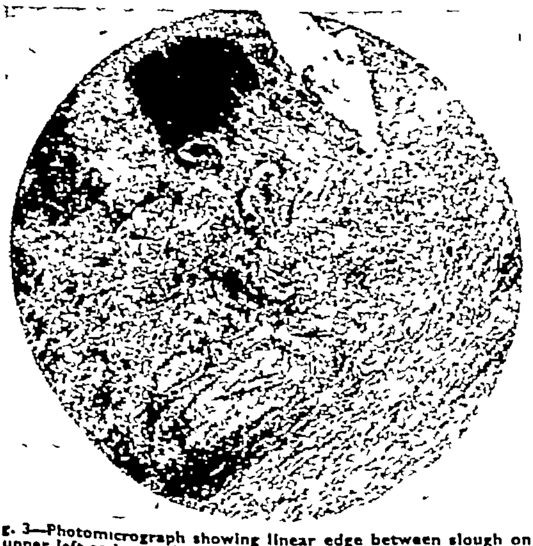

Fig. 3—Photomicrograph showing linear edge between slough on the upper left and granulation tissue. Note obliterating endarteritis. (×60.)

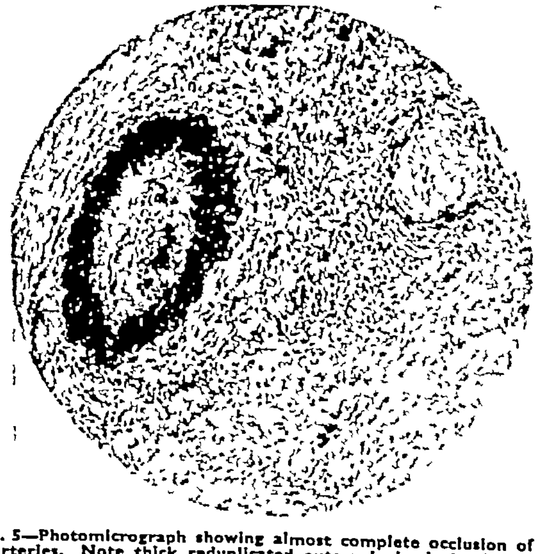

Fig. 5—Photomicrograph showing almost complete occlusion of two arteries. Note thick reduplicated external elastic lamina of the larger artery (orcein stain). (×115.)

Most probably the infection was acquired while bathing; and, though this is unusual, there are fully authenticated instances of leptospirosis canicola acquired in this way (Walch-Sorgdrager 1939, p. 336). There is no reason against the occurrence of bathing infections with *L. canicola*; dogs can contaminate water just as effectively as rats, though one must admit that there are fewer dogs and a smaller relative percentage of leptospiral carriers. The last figure is quite unknown. The incidence of canine infection, however, has been determined, chiefly by serological methods, in many parts of the world and is known to be high. In Amsterdam it seems to be greater than 30% (Walch-Sorgdrager 1939), in Philadelphia it is about 25% (Raven 1941), and in Glasgow Stuart (1946) has found antibodies to *L. canicola* in over 40% of street dogs. Klarenbeek (1938) states that more than 50% of dogs excrete leptospira for a variable period following infection; but since this period is often short, the percentage of dog "carriers" at any one time is probably small.

The clinical features of the present case generally accord with previous descriptions of leptospirosis canicola. The prominence of the renal symptoms, however, is noteworthy owing to the similarity of the disease as it occurs in dogs, but in the human case there is no evidence of a developing chronic nephritis. One cannot tell if the brief recurrence of nephritic symptoms is ascribable to the previous leptospiral disease. The dramatic change in the clinical condition following penicillin treatment is interesting and is in accordance with the experimental work of Larson and Griffitts (1945). On the other hand, a similar clinical course has been observed in patients where no specific therapy has been used. The disease is naturally self-limiting, and therefore no claim can be made for a specific therapeutic effect of penicillin.

SUMMARY

A case of leptospirosis canicola in a boy is ascribed to bathing in the Thames.

The diagnosis was established by the demonstration of a rising serum antibody titre to *L. canicola* during the course of the illness and by absorption tests with homologous and heterologous strains of leptospira.

The patient was treated with 220,000 units of penicillin, and dramatic clinical improvement followed.

PROGRESSIVE ulceration of the nose, palate, and wal of the antrum, known to ear, nose, and throat surgeon as malignant granuloma of the nose (Woods 1921), wa probably first described by McBride in 1896 (see McBride 1926), and about a dozen cases have since been published (Woods 1921, McKenzie 1922, McArthur 1925, Chatellier 1929, Kraus 1929, Goodyear 1930, Stewart 1933, Hall 1933, Dempsey 1933).

The lesion begins on the inferior concha or nasal septum and proceeds to sloughing of the concha and perforation of the septum and hard palate, the ulcerated areas having clearly defined margins. An abscess may form in the soft tissues of the cheek, with perforation of the anterior wall of the antrum. There is usually no regional lymphadenopathy. The lesions are not painful. There is a peculiar odoriferous bloodstained discharge from the affected nostril. The disease is usually rapidly fatal, though the precise cause of death is often obscure.

Bacteriological investigations have not incriminated any pathogenic bacteria, fungi, or protozoa, and Stewart (1933) reported negative results on animal inoculation. The Wassermann and Kahn tests have always proved negative, and there has been a complete lack of response to arsenicals (McArthur 1925). Apart from the local lesions in the nose, mouth, and antrum, necropsies have not revealed any specific changes, though in one of Hall's (1933) cases small nodules of reticulum-like cells were found in the lung and cortex of the kidney.

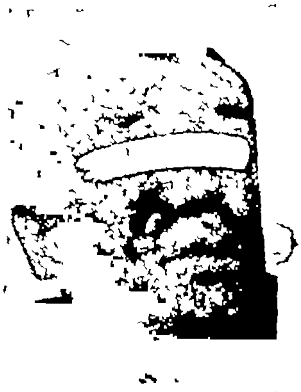

Fig. 1—Perforation of cheek and anterior wall of antrum exposing lateral wall of nose with necrotic anterior end of inferior turbinate bone.

The histology of the local lesion presents the general features of invasion by a cellular granulation tissue, with necrosis of bone and cartilage.

Muir examined McBride's (1926) case and stated that the condition did *not correspond to any* known type of ulceration, and in particular syphilis, yaws, and tuberculosis could be excluded.

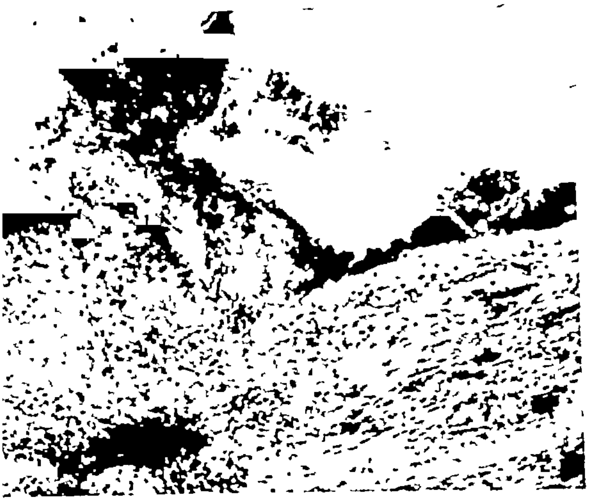
O'Sullivan, examining Woods's (1921) case, reported a zone of granulation tissue extending *into the healthy* tissue and breaking down behind.

In McArthur's (1925) case, Dew stated that the lesion did not conform to any known type of malignancy though bearing some resemblance to an atypical spheroidal-celled carcinoma.

Kraus (1929) described infiltration of bone and cartilage by a cellular granulation tissue and thought that sarcomatous change had supervened on an infective granuloma.

With regard to the granulation tissue, Chatellier (1929) thought there were resemblances to lupus pernio, and Ewing, examining Wood's (1931) case, thought that the changes resembled syphilis though they were not typical. Case, examining the same material, diagnosed tumour, and Weidman classified the condition as a granuloma.

Stewart (1933) described a round-celled infiltration of granulation tissue, engorged vessels, and scattered hæmorrhages, proliferating blood-vessels showed thickened walls and endarteritis with hyaline changes. Bone was actively destroyed. In one *case the appearances* suggested a fibroma.



ig. 2—Photomicrograph of section of ulcerated inferior turbinate bone. Note demarcation between necrosis and slough on the left and myxomatous connective tissue, with its colonies of fibroblasts and capillaries on the right. (×90.)

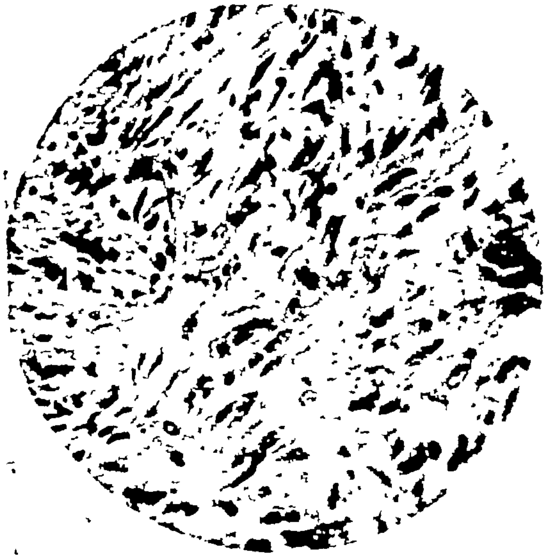


Fig. 4—Photomicrograph of cellular granulation tissue. (×320.)

Opinion seems to be more or less equally divided between describing the condition as an infective granuloma of uncertain ætiology and attributing the changes to a tumour growth.

All forms of treatment have been tried, from chemical cautery and surgical excision to radium implantation and X rays. Woods's (1921) second case was healed by radium needles placed in dental wax upon the ulcer-perforation. McArthur's (1925) case derived no benefit from radium, but showed satisfactory healing after three full doses of X-ray therapy. All other reported cases have been resistant to any form of treatment, and death has usually resulted from a vague cachexia or toxæmia coupled with repeated blood-loss from the lesion.

CASE-RECORD

A farmer, aged 58, was first seen by his doctor in May, 1945, with a history of a neuralgic pain involving the distribution of the second division of the 5th nerve. The teeth were carious, and it was thought that the neuralgia was due to sepsis in the upper jaw. *He did not take his doctor's advice to have dental treatment.* The first upper right premolar, canine, and lateral incisor teeth fell out during the next four weeks, followed by ulceration and necrosis of the adjacent alveolar margin.

The ulceration spread along the premaxillary region of the hard palate, destroying the mucosa. This was followed by a sloughing and necrosis of the bone, with formation of a fœtid sinus opening into the floor of the nose.

On August 29, 1945, the patient was seen at the Royal Salop Infirmary, when a hole 1 in. in diameter was found in the premaxillary region of the palate and the alveolar margin. There was also a tender red swelling over the anterior wall of the maxilla. A tentative diagnosis of syphilis was made, but the Wassermann reaction was negative. The patient was told to report in a week but did not, and was sent for on Sept. 17.

On the 19th the patient was seen again as an outpatient. He was cachectic from toxic absorption, with a very pale face, and had a temperature of 100° F. He talked with a nasal voice. The anterior end of the inferior turbinate was covered with a dirty greyish slough blocking the right nasal passage. The lateral wall of the nose beneath the inferior turbinate was eroded, and the whole of the anterior half of the floor of the nose was absent. Necrosis also involved the floor of the antrum. The septum was intact, and the disease was limited to the right nasal cavity. The middle turbinate was not involved.

After the sloughs had been removed from the nose the posterior third of the inferior turbinate was seen to be intact. This was seen with a nasopharyngoscope, it being impossible

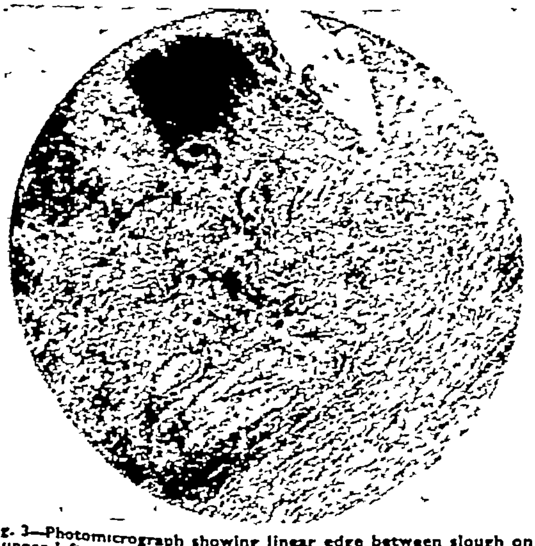

Fig. 3—Photomicrograph showing linear edge between slough on the upper left and granulation tissue. Note obliterating endarteritis. (×60.)

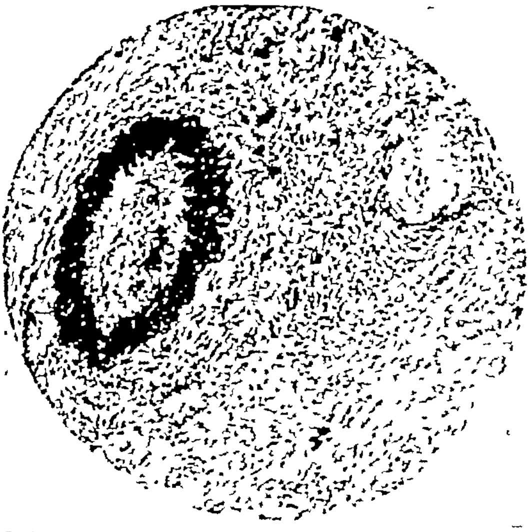

Fig. 5—Photomicrograph showing almost complete occlusion of two arteries. Note thick reduplicated external elastic lamina of the larger artery (orcein stain). (×115.)

Most probably the infection was acquired while bathing; and, though this is unusual, there are fully authenticated instances of leptospirosis canicola acquired in this way (Walch-Sorgdrager 1939, p. 336). There is no reason against the occurrence of bathing infections with *L. canicola*; dogs can contaminate water just as effectively as rats, though one must admit that there are fewer dogs and a smaller relative percentage of leptospiral carriers. The last figure is quite unknown. The incidence of canine infection, however, has been determined, chiefly by serological methods, in many parts of the world and is known to be high. In Amsterdam it seems to be greater than 30% (Walch-Sorgdrager 1939), in Philadelphia it is about 25% (Raven 1941), and in Glasgow Stuart (1946) has found antibodies to *L. canicola* in over 40% of street dogs. Klarenbeek (1938) states that more than 50% of dogs excrete leptospira for a variable period following infection; but since this period is often short, the percentage of dog "carriers" at any one time is probably small.

The clinical features of the present case generally accord with previous descriptions of leptospirosis canicola. The prominence of the renal symptoms, however, is noteworthy owing to the similarity of the disease as it occurs in dogs, but in the human case there is no evidence of a developing chronic nephritis. One cannot tell if the brief recurrence of nephritic symptoms is ascribable to the previous leptospiral disease. The dramatic change in the clinical condition following penicillin treatment is interesting and is in accordance with the experimental work of Larson and Griffitts (1945). On the other hand, a similar clinical course has been observed in patients where no specific therapy has been used. The disease is naturally self-limiting, and therefore no claim can be made for a specific therapeutic effect of penicillin.

SUMMARY

A case of leptospirosis canicola in a boy is ascribed to bathing in the Thames.

The diagnosis was established by the demonstration of a rising serum antibody titre to *L. canicola* during the course of the illness and by absorption tests with homologous and heterologous strains of leptospira.

The patient was treated with 220,000 units of penicillin, and dramatic clinical improvement followed.

CASE-RECORD

A farmer, aged 58, was first seen by his doctor in May, 1945, with a history of a neuralgic pain involving the distribution of the second division of the 5th nerve. The teeth were carious, and it was thought that the neuralgia was due to sepsis in the upper jaw. He did not take his doctor's advice to have dental treatment. The first upper right premolar, canine, and lateral incisor teeth fell out during the next four weeks, followed by ulceration and necrosis of the adjacent alveolar margin.

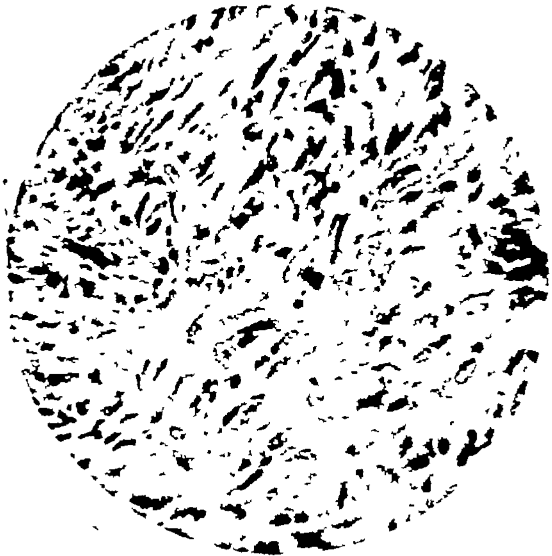

Fig. 4—Photomicrograph of cellular granulation tissue. (×320.)

The ulceration spread along the premaxillary region of the hard palate, destroying the mucosa. This was followed by a sloughing and necrosis of the bone, with formation of a fœtid sinus opening into the floor of the nose.

On August 29, 1945, the patient was seen at the Royal Salop Infirmary, when a hole 1 in. in diameter was found in the premaxillary region of the palate and the alveolar margin. There was also a tender red swelling over the anterior wall of the maxilla. A tentative diagnosis of syphilis was made, but the Wassermann reaction was negative. The patient was told to report in a week but did not, and was sent for on Sept. 17.

On the 19th the patient was seen again as an outpatient. He was cachectic from toxic absorption, with a very pale face, and had a temperature of 100° F. He talked with a nasal voice. The anterior end of the inferior turbinate was covered with a dirty greyish slough blocking the right nasal passage. The lateral wall of the nose beneath the inferior turbinate was eroded, and the whole of the anterior half of the floor of the nose was absent. Necrosis also involved the floor of the antrum. The septum was intact, and the disease was limited to the right nasal cavity. The middle turbinate was not involved.

After the sloughs had been removed from the nose the posterior third of the inferior turbinate was seen to be intact. This was seen with a nasopharyngoscope, it being impossible

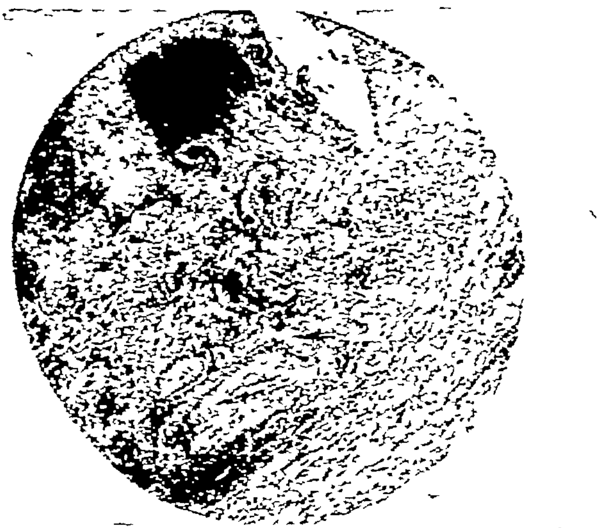

Fig. 3—Photomicrograph showing linear edge between slough on the upper left and granulation tissue. Note obliterating endarteritis. (×60.)

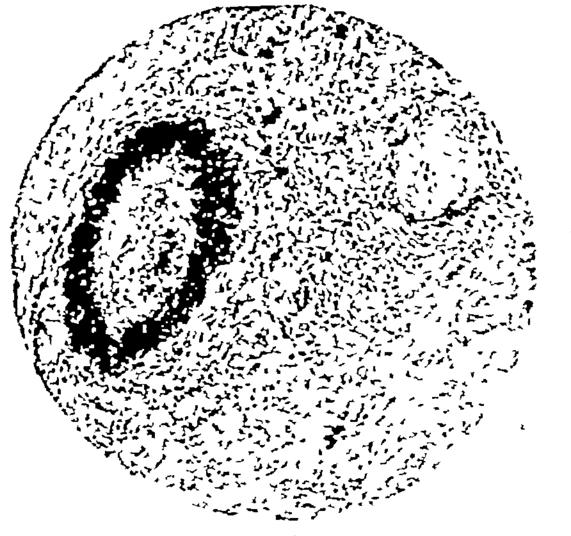

Fig. 5—Photomicrograph showing almost complete occlusion of two arteries. Note thick reduplicated external elastic lamina of the larger artery (orcein stain). (×115.)

to use a postnasal mirror owing to pharyngitis due to pus passing downwards. The bone forming the alveolar margin in relation to the right incisors, canine, and first premolar teeth, the anterior portion of the floor of the antrum, the right anterior half of the hard palate, and the medial half of the anterior wall of the antrum extending into the bony margin of the right nares and upwards towards the ascending process of the maxilla were absent. The floor and anteromedial margin of the orbit were intact.

The antrum contained a blackish-grey slough, which was removed with hydrogen-peroxide swabs. Beneath the slough there was a granulating surface with punctate hæmorrhages. The hole in the face (fig. 1) had a punched-out appearance, and its edges were smooth. The invading edge in the skin was spreading towards the vestibule of the nose medially, the spreading edge being hyperæmic, with a slough on its surface.

The ears and larynx were normal, and there were no glands in the anterior and posterior triangles of the neck.

He was admitted as an inpatient on Sept. 19.

Radiography showed the medial wall of the right antrum bulging into the right nasal fossa. Illumination of this antrum by X rays was normal. The remaining sinuses appeared normal. Radiography of the chest showed kyphoscoliosis (due to infection in childhood).

Treatment.—The cavity was swabbed three times a day with hydrogen peroxide to remove the sloughs, and insufflated with penicillin and sulphanilamide powder.

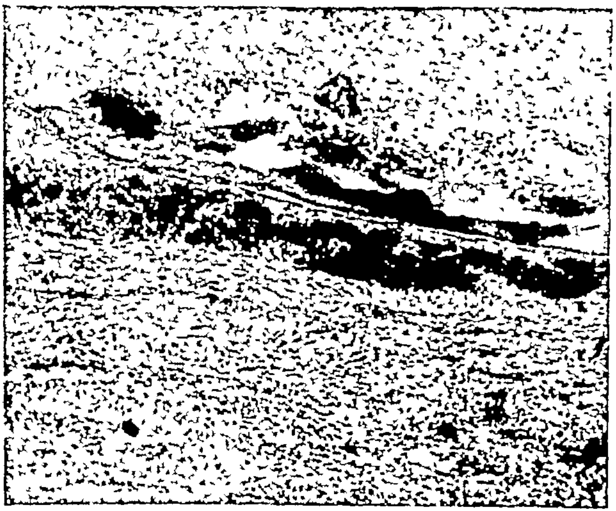

Fig. 6—Photomicrograph showing hæmorrhage and necrosis surrounding spicule of bone. (×90.)

Intramuscular penicillin 25,000 units was given three-hourly for three days. On this treatment the spread of the lesion was arrested, and the patient's condition appeared to be improving slightly; but he caught a "cold" and developed pneumonia, dying on Sept. 25.

Laboratory Findings.—The Wassermann and Kahn reactions were negative on two separate occasions, and the Sachs-Georgi test negative on one occasion.

Six swabs were taken on the 25th from different parts of the affected antrum, with identical results. Films showed numerous gram-positive cocci and diphtheroid bacilli only. Cultures gave growths of hæmolytic streptococci, a non-pathogenic *Staph. albus* (coagulase test negative), and diphtheroid bacilli of the xerosis type. No evidence of tuberculosis, actinomycosis, or mycosis. No growth of anaerobic bacteria.

Necropsy (Sept. 25).—Spine: kyphosis and lordosis presumably due to old-standing tuberculosis, with no evidence of present activity. Brain, skull, and middle ears normal. Right lung congested; some serofibrinous fluid in left pleural cavity secondary to lobar pneumonic consolidation of both upper and lower lobes. Kidneys small and shrunken; capsules stripped with difficulty, the microscopical appearances being those of atherosclerosis. Liver showed cloudy swelling. Remaining organs appeared to be normal. The appearances of the maxilla and face have already been described.

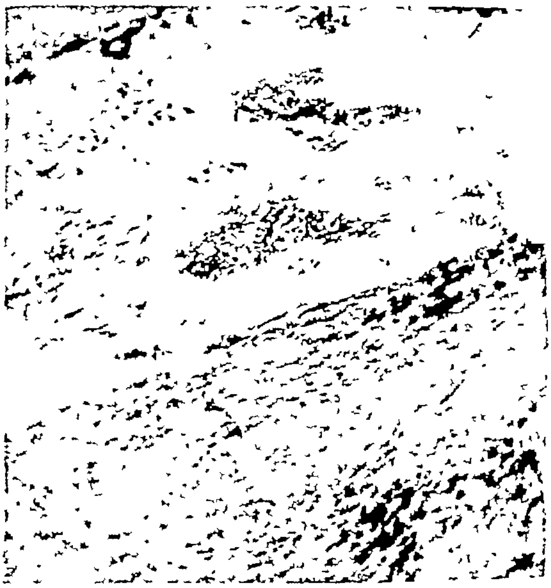

Fig. 7—Photomicrograph of part of same section as in fig. 6, showing fibrinoid type of degeneration which was an early lesion found closely applied to bone (Mallory's fibrin stain). (×160.)

Death was certified as due to lobar pneumonia and toxæmia from necrosis of right maxilla.

Histology.—Several pieces of tissue from the inferior turbinate bone (fig. 2), the hard palate, and the edge of the ulcerated area of the antrum were examined. The appearances throughout were similar, but were most pronounced in the edge of the perforation in the wall of the antrum. The mucosa was ulcerated away, and the surface was formed by a slough, consisting of masses of red cells, polymorphs, eosinophils, and plasma cells. Immediately under this superficial area was a wide zone of necrosis, where the outline of blood-vessels and connective tissue was just recognisable. There were no inflammatory cells in this area.

There was a sharp line of demarcation (fig. 3) between this zone and the next, which showed very cellular tissue (fig. 4) composed of closely packed interlacing fibroblasts and a few capillaries. Deeper still, the fibroblasts were arranged in long parallel lines and there was a moderate amount of collagen. Here also there were tortuous small arteries showing gross pathological changes. The adventitia was not clearly demarcated from the surrounding cellular tissue and showed infiltration with lymphocytes. The media was thickened, and

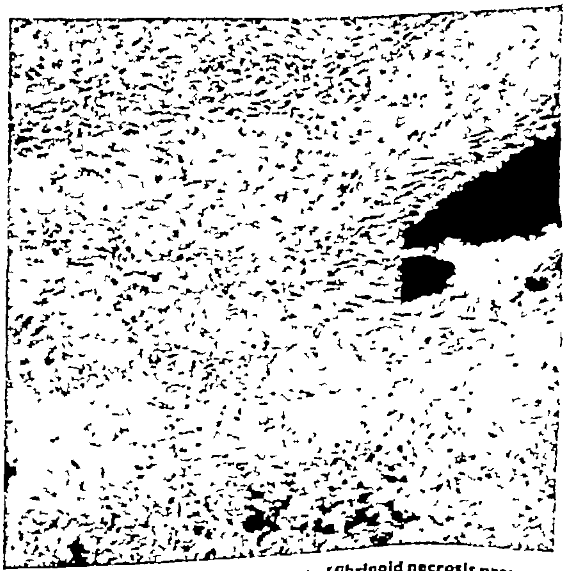

Fig. 8—Photomicrograph showing start of fibrinoid necrosis preparatory to sloughing. A spicule of bone is being isolated (Van Gieson). (×160.)

intima showed irregular proliferation; so the lumen was ost completely obstructed (fig. 5). In some of the arteries external elastic lamina showed much reduplication l a peculiar fragmentation. Outside the vessel wall were lections of red cells within a web of necrotic connective sue. Isolated spicules of bone were not invaded by the roblasts but were surrounded by œdematous fibrous tissue dergoing necrosis (figs. 6–8). There was no evidence of yloidosis.

In sections taken from other areas the necrosis was more early seen to involve bone and periosteum. It extended bands which surrounded the periosteum of isolated spicules d was associated with much hæmorrhage. Here the strucre of the granulation tissue was much less defined, and ere were isolated colonies of fibroblasts separated by yxomatous fibrous tissue, in which were several irregular pillaries. There was no evidence of tuberculosis, syphilis, carcinoma, and no protozoal or fungal elements were seen. Specially stained sections showed the only bacteria to be am-positive cocci and scanty gram positive bacilli in the ater margin of the zone of sloughing. By similar means the resence of more pathogenic bacteria, such as *B. lepræ*, *. mallei*, and spirochætes, either in this zone or deeper ones, as confidently excluded.

DISCUSSION

There seems to be little doubt that the present case as one of malignant granuloma of the nose; the clinical eatures correspond closely to those of previously pubished cases. In our case the lesion began near the ase of the carious teeth. The sloughing of the premaxilla, ith perforation of the hard palate, preceded a spread f the disease to the anterior wall of the antrum and o the inferior turbinate bone. The absence of bleeding rom the lesions was noteworthy. A slight point of ifference in our case from those previously reported as the absence of any gross hæmorrhages, even when arge adherent sloughs were removed.

The most interesting feature of this condition is its etiology. As regards the theory that the condition is nfective, no specific organism, protozoon, or fungus has ever been incriminated. In our case a hæmolytic streptococcus was isolated, but it is not suggested that its rôle was more than that of a secondary invader. In our case, as in the previous ones, the serological tests for syphilis were negative, and the appearances of the diseased cartilage and bone did not suggest any known infection. If the cause is an organism, perhaps a hitherto unidentified one, as suggested by Dempsey (1933), the reaction of the tissue is *unique* among infections, for there is virtually no evidence of the customary cellular defence mechanisms. Thus the necrotic area is sharply defined from the subjacent granulation tissue, but there is a complete absence of inflammatory cells at the interface of these zones. The absence of cellular defence has been emphasised by Stewart (1933) and well exemplified in a case described by Hall (1933).

As regards the theory that the condition is a true tumour, it may be conceded that there are certain arguments to support this view. In some published descriptions specific reference has been made to the similarity of the tissue to that found in fibromata and sarcomata. The failure of the usual treatment of a granulomatous lesion, and the reports of beneficial effects following the exhibition of X rays or radium, may be cited as evidence in favour.

In our case the noteworthy histological features were the presence of necrosis and degeneration, the cellular granulation tissue composed of young fibroblasts, and a process of obliterating arteritis within and behind this cellular zone. Though the histological changes appeared to suggest a new growth, no such tissue was found; the whole process seemed to be an erosion of existing normal tissue. We believe that this can be explained by the coexistence of two pathological changes keeping pace with one another: (1) a locally spreading lesion, the cellularity of which indicated the property of new tissue formation, whether this abnormal tissue be granulomatous or neoplastic; and (2) the obliterating arteritis, to which can be attributed the "fibrinoid" degeneration of the connective tissue with its accompanying small hæmorrhages, and the complete necrosis of more distant tissue. The resultant state was one of infarction; and both normal and abnormal tissues, if the latter were being produced, were afterwards lost in the sloughing of the infarcted area.

SUMMARY

A case of malignant granuloma of the nose in a man aged 58 is described.

The main feature was a rapidly spreading ulcerative condition involving the antrum, nose, and palate.

No specific organism appeared to be responsible, and serological tests for syphilis were negative.

Necropsy disclosed no specific changes apart from the local lesion.

The histological picture was that of an acute granuloma with necrosis.

It is impossible to decide whether the condition was due to an unidentified infection or to an unusual type of sarcomatous change.

PSYCHIATRY AT THE CORPS EXHAUSTION CENTRE

TECHNIQUE OF RAPID PSYCHIATRIC ASSESSMENT

F. P. HALDANE
M.B. Glasg., D.P.M.
MAJOR R.A.M.C.

J. L. ROWLEY
M.B. Belf.
CAPTAIN R.A.M.C.

THE corps exhaustion centre was established to prevent psychiatric casualties from impeding the evacuation and treatment of the wounded and sick when fighting was severe; to check secondary deterioration; and to select and deal with the relatively few men who would be fit for early effective return to fighting duties.

The exhaustion centre is a small medical unit staffed by a specialist psychiatrist, a psychiatrically experienced medical officer, and specially trained nursing orderlies. It is attached to another medical unit and so sited that patients can reach it within a few hours of being evacuated from their units.

In dealing with these patients the principal feature is the initial psychiatric interview, which usually has to be restricted to about 15 minutes. Its outcome determines whether the man has a reasonable prospect of effective return to action after not more than four or five days' retention at the centre. If there is no such prospect, he must be evacuated farther.

No elaborate treatment is provided. Arrangements are made to exclude or mitigate various likely sources of deterioration, suitable conditions for recuperation are provided as far as possible, and various adjuvant systems of medication may be prescribed; but recovery is largely spontaneous.

PSYCHOPATHOLOGY

Cases admitted to the corps exhaustion centre can be divided into three main groups, although they are seldom of unmixed type.

(1) *Normally Constituted Men who have Broken Down under Unusually Severe Stress.*—Situations sometimes arise in battle that render psychologically incapacitated for the time being any man involved, no matter how "tough" he may be. We have known all the unwounded survivors of some such incident arrive at the centre. Less intense psychic traumata will break down temporarily a normal man whose resistance is reduced by physical exhaustion or other minor illness. Repeated traumata tend to be cumulative. Other factors may

coöperate. Many of these men respond well to a few days' care at the centre. They constitute a minority of our admissions and are most numerous during heavy major actions.

(2) *Neurotically Disposed Men who have Developed Neurotic Symptoms under Stress.*—Most of these have to be evacuated. We will not discuss the psychopathology of these two groups; it has been discussed fully and often enough elsewhere.

(3) There remains a third group, which has been somewhat neglected. It is larger than the other two and often constitutes the majority of our cases at this level. The men in this group are not ill with a neurosis. They may even show little or no overt anxiety by the time they reach the centre. They may be said to have had their anxiety threshold lowered—a recurrence of the anxiety reaction facilitated. They may be men whose initial "anxiety threshold" was not high, or whose "anxiety tolerance" is low. But "low anxiety threshold" and "low anxiety tolerance" are not neuroses. Probably some of these men would develop neurotic symptoms if forced to continue in fighting duties, but they are not yet neurotic. They are simply men who have been badly frightened and are habitually too incapacitated by fear to be capable of effective action under fire. But their fear is appropriate to the conditions in which it arises; it is not pathological.

Some stigmatise these men as simply lacking in "guts." While deploring the emotional and subjective attitude implied in the use of the term "gutlessness," we have to admit that the reality concealed behind this appellation is the central factor in this type of psychiatric casualty and has to be estimated at the psychiatric interview.

These men may be evacuated from the line as casualties because, during a period of special stress, they have broken down, weeping and trembling and obviously unable to control themselves; they may be sent for psychiatric examination because their officers have found them to be useless and even burdensome "passengers"; or they may be sent for a psychiatric report because they are facing trial by court martial for desertion in face of the enemy. In its crudest form their disability manifests itself in the following features, which appear with the presence or threat of severe danger: inability to advance, inability to refrain from flight, inability to take appropriate action, inability to refrain from taking inappropriate action—they may leap from their trenches and rush about wildly while mortar bombs are bursting around, sometimes even rushing towards instead of away from the enemy's guns—or inability to appreciate clearly what is going on round them. These features may appear singly or combined. One or more may predominate in a given man. They have an impaired capacity, on the one hand, to maintain contact with reality and, on the other hand, to control their impulses in accordance with reality requirements. In other words, their basic ego-functions are involved. These men suffer from inadequate development of the ego. That is their essential disability. Accordingly, the main task of the psychiatric interview at the centre is to estimate the strength of the patient's ego.

TECHNIQUE OF RAPID PSYCHIATRIC ASSESSMENT

We have to provide for men who have no neurotic illness a 15-minute psychiatric interview which will reveal any subclinical neurotic trends and enable us to estimate the strength of the patient's ego. The taking of a standard psychiatric case-history is of very limited value and takes far too much time.

The ego is developed in childhood, especially in early childhood. It depends on the strength and constitution of the instincts, the anxieties and tensions connected with them, and the mechanisms used to master them, and is influenced by external conditions, especially the family pattern, the emotional attitudes and behaviour of the parents and others, and the social tensions within the home. But simple information about these external conditions tells us very little about the ego's development or of the strengths and weaknesses of the total personality. These external influences do not act in a direct mechanical way on the growing child. What is important is to know not that the father was harsh but exactly how the child interpreted this harshness; what phan-tasies he based on it; with what attitudes of submissi or revenge he reacted; what forms of identifications, introjections, and projections it stimulated; wha particular anxieties were aroused, and how they were dealt with; how all these and other processes influenced one another; how they influenced the general econom situation; and, in particular, how they advanced o retarded the adaptation of the ego to reality. The processes are detailed and complicated. They lie obscurely buried, largely in non-verbalised forms, in the depths of the patient's unconscious. They are protected by an elastic defence in depth of many and varied resistances, each of which would require painstaking, time-consuming, and patient efforts to breach. In short, their thorough assessment would require a prolonged and skilled analysis, which is obviously out of the question at a corps exhaustion centre.

We therefore had to devise a method compatible with a single interview lasting 10–15 minutes. The method we have adopted developed from our recognition that, after working laboriously through our routine examinations, we were really influenced very little by the facts we elicited from the patient. What really decided our disposal of him was our intuitive judgment of his personality, based on his appearance, manner, and behaviour throughout the interview.

Psychiatric intuition, to be reliable, requires the maximum of behavioural activity from the patient, so that its judgments may be adequately grounded. This in turn requires the establishment of good rapport—i.e., some degree of positive transference. The adoption of any stereotyped systematic technique, approaching in any way a questionnaire, militates against the establishment of these necessary conditions; by its rigidity and its impersonality it reduces transference, and by increasing the activity of the psychiatrist it reduces that of the patient.

On the other hand, the value of intuition has serious limitations. It will vary from one psychiatrist to another and even from day to day in the same psychiatrist. The interview must be so conducted that the patient will provide the richest display of behaviour suitable fo the stimulation of psychiatric intuition, along with th maximal content suitable for rational evaluation i terms of ego strength.

The function of the ego is the integration of emotiona attitudes and behaviour so as to ensure the greatest advan-tages in relation to environment and to avoid painful intra-psychic tension. Successful function of the ego therefor depends on extensive and accurate testing of reality and o competent control of conscious and unconscious psychic force . The weak ego manifests its weakness in its relative failu in these various directions. Contact with reality is too limite insufficiently firm, and incoherent; the individual's behaviou is poorly integrated and too strongly swayed by unconsciou motives and instinctual demands. The positive finding would include, for example, restriction of range of interests deficiency of externally directed activity, either habitual o in the face of real difficulties; more or less complete loss o contact with reality under special stress, followed by undu delay in full resumption of reality testing; diffusion of effor through inconstancy or incompatibility of aims; decrease ability to postpone satisfaction of desires or to tolerate thei frustration; and a general lack of good sense in the conduc of affairs. Such findings justifiably support the decision th a patient's ego is excessively weak.

The interview is simply a short conversation with th patient, in which we ensure that he does very muc the greater part of the talking. We open it with som commonplace greeting and let it take its course, guidin it as unobtrusively as possible to the subjects we thin will be most helpful. So long as the topic is effective i stimulating affective and other responses from th patient, we allow or urge him to continue. So soon a we feel we have exhausted the fruitfulness of any topic we intervene, as easily and as naturally as possible, t change the direction of the deliberately one-sided con-versation. Any topic may be found suitable. We may induce him to discuss his sources of pleasure and enjoy-ment or his difficulties in civil or in Army life, his inter-ests, his family relationships, other domestic matters, &c. We do not set ourselves to cover any particular ground;

and in general it is very much better to get a vivid and detailed account of some limited aspects of his experience than to spread the inquiry more broadly and so get more superficial responses.

In our experience one topic has usually occupied the foreground of our interviews, and it is one that, along with family matters, is most liable to be spontaneously introduced by the soldier. It is also especially relevant to our more specific aims. This is an account of his latest battle experience. We try to get it as full and as detailed as possible, trying in particular to gain the maximal insight into his affective responses to battle, his particular fears and his defences, and the quality of his behaviour on the battlefield. Because of the freshness of our cases, the affective responses are often more accessible to study here than they would be farther back along the line of evacuation; many of our patients, when they reach the exhaustion centre, still show the tail-end of the physiological anxiety reactions that were stimulated in battle.

Such an interview gives us information on the existence and importance of "neurotic increments" which may be indicated by accounts of subclinical neurotic reactions, such as avoidance of quarrels or excitement, nervousness in company, difficulties with superiors, excessive fearfulness in the dark, &c. But, most important of all, it gives us a short sample of the patient's active living behaviour, on which we can base our intuitive assessment, the most decisive factor in deciding our disposal of the case.

CRITICISM

The technique we have described is open to a number of objections. We shall mention only three that seem important.

(1) Our intuitive judgment of the patient is not really a direct assessment of the strength of his ego. What we gain is an impression of his personality, his externally perceptible qualities. We do not know what relationship exists between ego and personality in this sense. We have taken an impression of weakness of this personality as an indication of the weakness of the ego. This is an assumption without theoretical backing.

(2) We have treated weakness of the ego as a unitary condition. It is probably not so. Weakness of one set of ego functions does not necessarily imply weakness of all the others. Thus, because a man has excessive difficulty in restraining the desire for flight, it does not follow that he is excessively prone to lose touch with reality under stress. This is obviously very relevant to the decision about his disposal.

(3) Finally, weakness of the ego is probably much more variable than, for instance, weakness of the intellect. The ego may be fortified by such factors as good unit morale and leadership. It is therefore difficult to decide what degree of apparent weakness precludes operational effectiveness.

In spite of these and other shortcomings we think that this is about the best that we are at present able to do in so short an interview. We get a rough but clearer and probably more accurate picture of the patient and a fuller insight into his military effectiveness than results from adherence to the standard routine of attempting to take a full psychiatric case-history in the time available.

We hope that the method here described may be of some use to civilian psychiatrists. With the increased demand for psychiatric services that seems likely to arise now that peace has returned, it may well be that, for some time at least, similar superficial methods may be required. Even apart from this, occasions arise when we wish to gain a quick picture of our patient at our first interview, and some appraisal of the ego strength is necessary in deciding the form of therapy and in making a prognosis.

Cases seen at the front are in an emotional state which renders the "impressionistic" technique indicated especially fruitful. This is far less so in cases seen under ordinary circumstances. However, it still seems worth while to draw attention to the ego functions, to the importance of assessing their effectiveness, and to the general lines of inquiry along which such an assessment may be conducted.

SUMMARY

The nature and functions of the forward military psychiatric unit (corps exhaustion centre) are described.

Cases seen comprise (1) normal men who have broken down under excessive stress, (2) neurotically predisposed men who have developed neurotic symptoms under stress, (3) men who merely do not function effectively as soldiers under stress.

The psychopathology of the third group is discussed. Weakness of the ego is considered to be the essential defect.

The most suitable technique for a psychiatric interview aimed at assessing ego strength and restricted to 10–15 minutes is discussed. Reliance on psychiatric clinical intuition as the main decisive factor is recommended.

Our thanks are due to Brigadier J. H. Bayley, D.D.M.S. 5 Corps, for permission to publish this paper.

MALTED FOODS FOR BABIES

TRIALS WITH YOUNG RATS

HARRIETTE CHICK E. B. SLACK
C.B.E., D.Sc. Lond. and Manc. B.A. Camb.
From the Lister Institute of Preventive Medicine, London

A MALTED food for infants to provide a supplement or substitute for milk, when this is very scarce, was by Dr. G. Caprino in the laboratories of Peroni's brewery in Rome and was called by him 'Maltavena.' His formula was brought to the notice of the health division of the European Regional Office of UNRRA, at whose request we have tested on young growing rats the value of such mixtures as sources of proteins and B vitamins.

The maltavena preparations supplied to us were of two types: one containing, on a solids basis, extract of malted barley about 80%, wheat flour (80% extraction of the grain) about 10%, and skimmed-milk powder about 10%; the other containing 10% soya flour in place of the milk powder. Both the wheat flour and soya flour had also been subjected to digestion with the enzymes of malt extract for a short time. Of the materials tested in the following experiments, two, A and C, were of the first type, and three, B, D, E, contained soya flour; their percentage composition was approximately as follows:

Maltavena preparation	*Malt extract*	*Wheat flour*	*Soya flour*	*Skimmed-milk powder*
A	80	10	—	10
B	80	10	10	—
C	80	10	—	10
D	80	10	10	—
E	70	10	10	10

All were supplied in the dry form and were ground to a fine powder before being fed to the rats.

EXPERIMENTAL

The criterion adopted was the capacity to support growth in newly weaned rats. For this purpose, diets were constructed which consisted mainly of the malted food to be tested and their value was estimated in comparison with that of diets containing a similar percentage of protein derived from milk powder. The proportion of protein, carbohydrate, and fat was similar in all the diets on which growth was compared.

The following procedure was adopted in all the experiments quoted unless otherwise stated. The young rats (Lister pied strain) received the experimental diets a few days after weaning, when their body-weight was about 40–50 g. Litter mates were divided into groups of equal average body-weight, with equal distribution of males and females, and to these groups were allotted the different diets to be tested. To provide a standard for comparison, each experiment included a control group maintained on a diet containing an equal content of protein derived exclusively from skimmed-milk powder. The diets made with the malted foods contained about 90% of these materials, with 2% of a salt mixture

TABLE I—COMPOSITION OF DIETS (PARTS PER 100 g.)

Average nitrogen content (% on air-dry wt.) ..	1·70	1·77	1·79	1·74	1·77	1·67	1·65

* Milk control. † McCollum's no. 185.
‡ These amounts were given to bring the total to about 4%; the soya flour contained 22% fat.
§ Extra salt mixture added as diet 7a contained no milk powder.

(McCollum's no. 185); in some trials extra fat was added to bring the total up to about 4%. In the experimental diets the malted food provided the protein and the carbohydrate; in the milk-powder control diets sucrose was added to make a corresponding proportion of carbohydrate. The composition of some representative diets is shown in table I.

Each rat received daily 2 drops of cod-liver oil, to supply vitamins A and D, and (except in experiment IV) 1 c.cm. of a protein-free aqueous yeast extract (=0·5 g. of dry yeast), to provide B vitamins. The proportion of nitrogen, reckoned on a solids basis, was arranged to be about the same in the diets compared in any one experiment; it varied in the different trials from 1·6% to 1·8%, representing about 9·5–11·0% of "crude" protein. These amounts are suboptimal for the growth of young rats and were purposely so arranged to ensure that the protein content was the factor limiting growth. All other essential nutrients were present in adequate amounts.

Expt. I.—In this test comparison was made of the nutritive value of the protein and other nitrogenous substances present in maltavena A and B. The diets 1 and 2, incorporating products A and B respectively, as fed to the rats, contained 1·6% of nitrogen, or about 9·6% of crude protein. The control diet with skimmed-milk powder also contained 1·6% of nitrogen.

The rats on diet 2 thrived better than those on diet 1, but less well than those on the control skimmed-milk-powder diet. The rats on the control milk-powder diet developed a scaly condition of the skin on paws and tail after about seven weeks owing to the lack of unsaturated fatty acids. The condition improved with the addition of 4% of lard. Rats receiving soya flour (diet 2) had no skin affection, because the fat in the soya bean contains a high proportion of unsaturated acids (Durkee 1936).

Expt. II.—The malted products C and D tested in this experiment and in experiment III had a total nitrogen content of 1·3–1·5% on the dry weight, which is too low for a satisfactory test with young rats. Accordingly 10% of skimmed milk powder was added to each. In this way the percentage of nitrogen in diets 3 and 4, made with these two products respectively, was raised to 1·7–1·8% (the crude protein being 10–11%). The milk-powder control diet 5 was arranged to correspond (see table I).

This increase in protein content was accompanied by a better rate of weight increase than in experiment I. On diet 4, containing maltavena D with soya flour, the rats progressed almost as well as on the milk-powder control diet; the performance on diet 3 was inferior. The average weekly weight increase in 32 days on diets 3, 4, and 5 was, respectively, 10·0, 13·6, and 13·9 g. (see figure).

Expt. III.—In this test lard was added to each diet in amount to make the proportion about 3·5% in the diet (see table I). The performance of the young rats was compared on diets 6 and 7 (table I), which contained the malted products C and D respectively, after the addition of extra milk powder to each, as in experiment II. An additional diet, 7a, was tested, in which 6% of soya flour was added to maltavena D to provide an amount of nitrogen equal to that in the extra milk powder. The control diet 8, with all protein derived from the milk powder, was included in the experiment.

In all groups the rate of weight increase was satisfactory, in view of the low level of protein in the diets for these rats. With diets 7 and 7a, containing soya flour, growth was as good as with the milk-powder control diet 8, the average weekly weight increases being 15·5, 14·4, and 14·6 g. respectively. On diet 6, containing malt extract with wheat flour and skimmed milk powder, the weight increase was less (average weekly increase 12·8 g.) in spite of the fact that about half of the protein was derived from milk protein (see table II).

It may be concluded that the growth-promoting value of the mixture of proteins of malt extract, wheat, soya flour, and milk as contained in diet 7, and that of the mixture of those of malt extract, wheat flour, and soya flour as contain in diet 7a, were equal to the value of milk proteins.

TABLE III—EXPT. IV (DURATION OF TEST 49 DAYS)

Diet 9	Composition (parts per 100 g.)	—	No. of rats	Av. body-weight (g.)		Av. week increa (g.)
				Initial	Final	
Maltavena E	94	With yeast extract 1 c.cm. daily	4	44	139	13·
Salt mixture	1					
Lard ..	4	Without yeast extract	4	43	132	12·
Nitrogen content (%)	1·7					

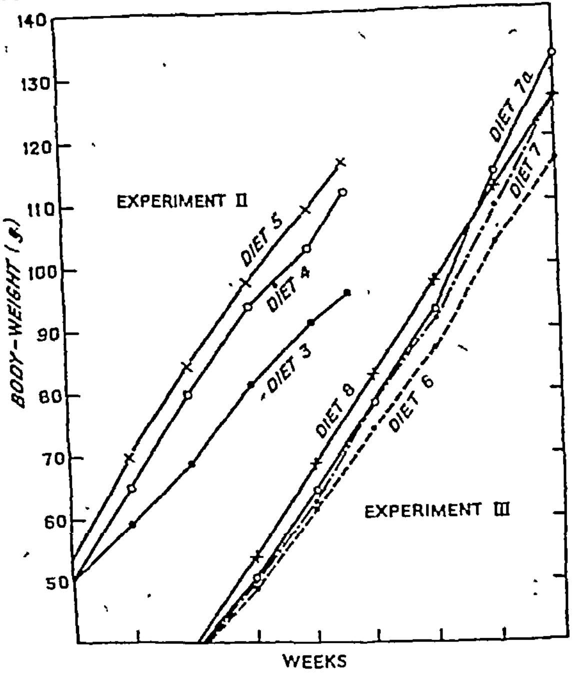
Expt. IV.—Extracts of malted barley and the soya bean a both known to be good sources of B vitamins. For this te diet 9 was composed of maltavena E with salt mixture a lard; the nitrogen content of the diet was 1·7% (see table II

A single litter of newly weaned rats was divided into tw groups of 4 rats; both groups received this diet with the usu daily dose of 2 drops of cod-liver oil. One group receiv additional B vitamins as 1 c.cm. of yeast extract daily; th other group received none. After seven weeks there was slight, but doubtfully significant, advantage in the averag body-weight of the rats on extra B vitamins, the respecti figures for the two groups being 139 and 132 g. and the averag weekly increases 13·6 and 12·7 g.

TABLE II—EXPT. III (DURATION OF TEST 6 WEEKS)

Material tested	Diet no.	Av. nitrogen content (%)	Protein (N × 6) content (%)	Percentage (approx.) of protein derived from—				No. of rats	Body-weight (av.	
				Malt extract	White flour	Soya flour	Skimmed-milk powder		Initial (g.)	Av. weekl increase per rat (g.)
Maltavena C* + extra skimmed-milk powder 10%	6	1·74	10·4	32	10	..	58	6	39·5	12·8
Maltavena D* + extra skimmed-milk powder 10%	7	1·77	10·6	34	11	30	24	5	39·0	15·5
Maltavena D* + extra soya flour 6%	7a	1·67	10·0	34	10	56	..	6	39·7	14·4
Milk-powder control diet	8	1·65	9·9	..	..	..	100	6	38·2	14·6

* See table I.



Average weight curves of 5-6 rats on diets in which nitrogen was derived from the malted preparations, compared with those of rats on control diets containing an equal proportion of nitrogen derived from milk. For particulars of diets see tables I and II. Diets 5 and 8 are milk-powder control diets.

This result indicates that maltavena containing soya flour, if used for baby food, would not need supplementation with food yeast or synthetic B vitamins.

DISCUSSION

The results of the tests indicate that a combination of malt extract about 70 parts, wheat flour about 10 parts, and soya flour about 16 parts (on a solids basis) possesses a mixture of proteins whose growth-promoting value for young rats is about equal to that of the proteins of milk. When 10 parts of skimmed-milk powder replaced about half of the soya flour, the growth was not increased to a significant extent (experiment III). It is concluded that the enhanced worth of the mixture is due to the supplementary action for one another of the proteins contained in the different ingredients. The proteins of the soya bean, in common with those of other legumes, have been shown to have a supplementary effect for those of rice or of white wheat flour (Indian Research Fund Association 1946; Jones and Divine 1944). We have confirmed this fact for white wheat flour and the sample of soya flour used in the manufacture of the foods tested in the present work (Chick and Slack 1946). It is possible that the protein in the malt further supplements those in the wheat and soya flours. Everson et al. (1944) have shown that the nutritive value of soya protein is increased by germination of the beans. We, however, did not find any enhancement of the growth-promoting value of barley after malting.

With the experimental rats in the present work, better growth and healthier animals were obtained when the diet contained about 1·8% of nitrogen or about 11% of crude protein (on a solids basis) than when the proportion was lower. The human baby, however, with its much lower growth-rate, presumably requires less protein in its diet than the rat, judging from the low proportion of protein in human milk compared with that of the rat. But since the biological value of the proteins in human milk may be greater for the human infant than that of any artificial mixture, a proportion of about 11% of protein in the diet would not seem too high.

The composition of these malted foods was originally so arranged that, when diluted for consumption, it should equal that of human milk in calorie value and in content of proteins and total minerals, and the results of our experiments indicate that the maltavena preparations containing about 16% soya flour, owing to the supplementation *of the various proteins contained* in the constituents, may meet the protein requirements of an infant and provide a sufficient supply of B vitamins.

Maltavena, however, even when compounded with soya flour in the amount included in diet 7a, is very deficient in fat (possessing about 1/6 of that in human milk) and in fat-soluble vitamins. The latter can be easily supplied by a small dose of cod-liver oil. To what extent the fat in a food for infants can be replaced by an isodynamic equivalent of carbohydrate is uncertain. Owing to milk shortage in Vienna during the war of 1914–18 attempts were made at the University Kinderklinik to feed babies on dilute skimmed cow's milk to which sugar was added to bring the calorie value up to that of human milk. These results were unsatisfactory, but the importance of fat-soluble vitamins was not appreciated at that time. As a routine measure the director, Prof. C. von Pirquet, reduced the fat in the diet of the babies in the clinic to half and substituted an amount of cane-sugar of equal energy value. The infants thrived during the summer on this diet, but developed rickets in the winter; the addition of cod-liver oil prevented the rickets (Chick et al. 1923).

Only clinical trials can decide whether the human infant will thrive on a diet which, though containing enough good protein, suitable carbohydrate, and the necessary minerals and vitamins, has a fat content which is only a small fraction of that in its natural food.

CONCLUSIONS

The nutritive value of the proteins contained in the different samples of maltavena received, and in modifications of these, was measured by their power to support the growth of young newly weaned rats, in comparison with that of milk proteins.

Of the mixtures tested, the one *containing malt extract* 70%, wheat flour 10%, soya flour* 10%, and powdered skimmed milk 10%, with total nitrogen about 1·8%, proved the most advantageous. The combined supplementary action of the different proteins it contained rendered the mixture equal in growth-promoting value to the mixture of proteins in milk, when fed in a diet of equal nitrogen content.

Though the mixture of malt extract with wheat flour 10% and soya flour 16% was as efficient as that in which skimmed-milk powder 10% was substituted for about half the soya flour (experiment III), it would seem safer, on general grounds, to include a small proportion of milk powder in any infant food.

We wish to thank Glaxo Laboratories Ltd. and Ovaltine Research Laboratories (A. Wander Ltd.) for the supply, on behalf of UNRRA, of the maltavena preparations; Mr. G. W. Flynn for his technical assistance; and Sir Charles Martin for his hospitality at Roebuck House, Cambridge, where the work was carried out, and for his constant support and helpful criticism.

* Soya flour is well provided with calcium and phosphorus, containing about two-thirds of the amount present in dried cow's milk, but there is less calcium than phosphorus, whereas in milk the reverse is true. Many workers using soya flour for infant feeding have therefore added a small amount of a calcium salt (see Mackay 1940).

Reviews of Books

Child and Adolescent Life in Health and Disease

W. S. CRAIG, B.SC. Glasg., M.D. Edin., F.R.C.P.E., formerly first assistant in the department of child life and health, the University of Edinburgh; with a foreword by Prof. Charles McNeil, F.R.C.P. Edinburgh: E. & S. Livingstone. Pp. 667. 25*s.*

THIS book appears appropriately at a time when the child-health services are under review, and when pædiatrics is taking an increasingly important place in the training of both medical students and postgraduates. Professor Craig has divided his comprehensive work into four main sections and a number of appendices. The first part, which is historical, deals with the early development of systematised care for children from the haphazard and often chaotic results of private philanthropy and poor-law administration. The second, and major, part deals with care of child life at the present time. This section includes particulars of organisations dealing with homeless children, provisions for juvenile delinquents and for handicapped children, the maintenance of health, treatment of the sick, and care of children under conditions of total war. The third section, on "the spirit of future endeavour," is surprisingly slight considering the importance of the subject, and barely touches many of the problems suggested by the subtitles. Finally there is a first-class summary of the more important legislation dealing with child health and care. Where there is so much to praise, it is perhaps mere carping to suggest that there are rather too many pleasing studies of child life among the illustrations. Regarded as a social study, the book is unique at present and contains a great deal of information not readily accessible elsewhere. It should be useful both to the public-health worker and the clinician concerned with child health.

The Osseous System

VINCENT ARCHER, M.D., professor of roentgenology, University of Virginia. Chicago: Year Book Publishers. London: H. K. Lewis. Pp. 320. 33*s.*

THIS is the fourth of a series of six handbooks on radiological diagnosis. It is well produced with many good illustrations of the common bone diseases and abnormalities. The text is brief and to the point and references between text and illustrations are very easy to follow. These handbooks are a cross between an atlas and a textbook—a difficult species to breed with success. This one is a success because rarities are omitted and emphasis is placed on common mistakes observed over a period of twenty years in a teaching hospital. The best section is on bone abnormalities in childhood, and the book can be heartily recommended to students studying for a radiological qualification.

Tropical Nutrition and Dietetics

(2nd ed.) LUCIUS NICHOLLS, M.D. Camb. London: Baillière. Pp. 370. 27*s.* 6*d.*

NUTRITION in the tropics differs but little from nutrition in temperate regions as regards the quantity and the quality of the food which is essential to preserve health; the differences lie chiefly in the fact that the inhabitants of the tropics eat foods which differ in their composition from those eaten in temperate regions. There have been very few investigations in the tropics concerning whether more or less of any dietary constituent is required to maintain the body in a state of good nutrition, but a book of this kind should review them. The increased requirement of sodium chloride in the warmer parts of the tropics is lightly passed over, however, and the severe deficiency arising in heat exhaustion is not mentioned. In all who live in the tropics the basal metabolic rate is believed to be reduced by some 10%; but none of the published observations on this important point are specifically mentioned.

The author shares the belief of some other doctors in the tropics that the indigenous people need less food, though no colour bar has been detected in the field of human nutrition. Thus he affirms that an adult male labourer in the tropics, in view of the fact that he weighs only 52 kg. (almost certainly because he is poorly nourished), needs only 1500 calories for basal metabolism, 600 calories for minor activities outside his working hours, and 400–500 calories for his work. His protein requirements, however, are set at 65 grammes and his fat requirements at 50 g.—both liberal estimates. Other requirements are assessed at calcium 0·5 g., iron 8 mg., vitamin A 1800 units, nicotinic acid 20 mg., ascorbic acid 40 mg., and thiamine 0·4 µg. for each non-fat calorie. Some of these figures are distinctly low when compared with those which are generally accepted in other parts of the world. The discussion on the vitamins and minerals is otherwise detailed and accurate; the section on thiamine and beriberi is exceptionally good, largely because in this field workers in the tropics have made a unique contribution to knowledge. Such effects of protein deficiency as nutritional œdema, however, are too briefly discussed, and there is almost no mention of necrosis of the liver or of cirrhosis. Casein hydrolysates and the administration of plasma are not mentioned; kwashiorkor is dismissed as of no account; and nutritional iron-deficiency anæmia is considered to be almost an impossibility in the male.

The tables on the analyses of tropical foodstuffs are useful and accurate, but the approximate wastage in preparation might have been indicated. The discussions on the different tropical foodstuffs and public-health aspects of nutrition are some of the best in the book. On the whole Dr. Nicholls fairly presents what is known in the field of tropical nutrition, but sometimes fails to discriminate between the established facts—all too few—and the speculations—all too many.

Evolution of Plastic Surgery

MAXWELL MALTZ, M.D., SC.D. New York: Froben Press. Pp. 368. $5.

IT was a happy inspiration of Dr. Maltz to give us an outline of the history of plastic surgery from primitive times to the present day. Reparative surgery began in the hard school of war, and today ample scope has been given for the skill of modern surgeons, especially in facial plastic surgery—though some of the new modern methods are but refinements and improvements of the old. The Greeks and Arabs made little contribution to the evolution of plastic surgery. In the 10th century the Jews gained fame as physicians and surgeons but in 1267 the Council of Venice prohibited Jews from practising on the body of any Catholic believer, and the study of anatomy was likewise forbidden. During the Middle Ages plastic surgery languished, for the Fathers of the Church regarded anything pleasing to the eye as a temptation of the devil. It was only after the foundation of Salerno University that the Italian physicians revived surgical art in modern Europe. The University of Bologna followed, where in the 16th century the great Tagliacozzi—sometimes called the father of plastic surgery—arose and gave his name to an operation for rhinoplasty. General and local anæsthesia have favoured the evolution of modern surgery. Gillies's use of the direct-flap method is fully described, and the author pays tribute to his brilliant pioneer work and that of Vilray Blair of the United States.

Pneumoperitoneum Treatment

A. L. BANYAI, M.D., F.A.C.P., associate clinical professor of medicine, Marquette University, Milwaukee. London: H. Kimpton. Pp. 376. 33*s.*

OUTSIDE the world of pulmonary tuberculosis pneumoperitoneum is generally known as an occasional diagnostic and therapeutic measure. The use of intraperitoneal oxygen or air in the treatment of tuberculous peritonitis dates back 50 years, but it is only in the past few years that the indirect effects of pneumoperitoneum on the lungs have been used at all extensively. The air in the abdomen pushes the diaphragm up into the chest, and thus affects the capacity of the thorax. When used in conjunction with paralysis of the phrenic nerve the elevation of the diaphragm can be considerable and is a valuable addition to collapse therapy. It is usual to use pneumoperitoneum in conjunction with phrenic-nerve interruption or artificial pneumothorax, since its effects alone are not extensive enough to be of great value. In a comprehensive and detailed study, Professor Banyai deals with all aspects of the procedure. Generally speaking complications are rare, though peritoneal effusion is sometimes encountered; the risk of damage to bowel is not likely to be overlooked by

LIKE EXPELLING WATER FROM A SPONGE

ŒDEMA due to cardiac failure

Control of œdema lightens the work of the failing heart. Digitalis and other cardiac tonics can again show beneficial action.

Using 'Salyrgan,' dropsical accumulations are rapidly drained from the tissues and œdema is kept at a minimum. The preparation may be administered either in ampoule or in pellet form.

'Salyrgan' is supplied in amps of 1 c.c. and 2 c.c. in boxes of 5, 25; and in pellets of 0.08g. in tubes of 20, bottles of 250.

'SALYRGAN'

TRADE MARK BRAND OF MERSALYL

SURFACE ANÆSTHESIA WITH 'DECICAIN'

'Decicain' penetrates the mucous membrane deeply and produces rapid and prolonged surface anæsthesia. It is non-irritant, is stable in solution and can be sterilized by boiling.

'Decicain' is ten times more powerful than cocain, and is used in correspondingly weaker dilutions. It is not subject to the Dangerous Drugs Act.

'Decicain is supplied as follows :—

Substance in bottles of 1 g. & 5 g.	*Tablets in tubes of 10 x gr. 1½ (0.1 g.)*
Solution 2% in bottles of 1 oz.	*Ointment 1% in jars of 1 oz.*

Lozenges gr. 1 in bottles of 12.

B.D.H. ŒSTROGENS

In the treatment of the Menopausal Syndrome

The use of œstrogens for the control of menopausal symptoms is an established practice. The following B.D.H. œstrogens are available :—

OESTROFORM

Oestroform is the most generally satisfactory preparation for menopausal patients. Treatment is by means of injection; therefore it is completely under the control of the physician.

STILBŒSTROL B.D.H.

Stilbœstrol is still regarded as the most effective of the synthetic œstrogens; it is administered orally and produces nausea only in relatively few patients.

DIENŒSTROL B.D.H.

Dienœstrol is therapeutically similar to stilbœstrol with the advantage that it does not cause any nausea even in susceptible patients.

Stilbœstrol-D.P. (Stilbœstrol Dipropionate B.D.H.) and Hexœstrol B.D.H. also are available.

Details of dosage and other relevant information on request

A non-greasy ANALGESIC OINTMENT

PRODUCT OF THE GLAXO LABORATORIES

Relief of pain and discomfort within a few minutes and lasting two hours or more is obtained after the simple, direct application of 'Anethaine' Ointment to the skin or mucous membrane.

'Anethaine' Ointment is non-greasy and is readily removed with water from the skin or clothing. It contains 1.0 per cent. of the fat-soluble base of amethocaine hydrochloride.

For the relief of pain in haemorrhoids and skin diseases generally. Many other uses will suggest themselves to doctors.

ANETHAINE

Ointment

Available in ½ oz. TUBES

A Joint Enterprise

MEDICINE and nursing are one art, its aim the care of the patient. If medicine goes on growing, as it must, while nursing is suffering a decline, the achievements of one will be offset by the failures of the other. However sure the diagnosis, neat the operation, or apt the drug the patient dies or suffers if he is badly nursed. Doctors have thus towards the nursing profession a duty of which nowadays they seem hardly aware. In the early days of modern nursing the nurse looked to the doctor for advice and help in developing her specialty, and the results of that collaboration have been an example to the world. Indeed, many of the principles laid down in that atmosphere of confidence and endeavour have stood the test of a century of nursing practice. The founding of the State examination, which placed nursing finally on the footing of a profession, should have strengthened the partnership, doctors and nurses working together as colleagues. In practice there has been something of a break, for which both professions must accept blame. The doctors, probably from inertia, have lost interest in the training of the nurse, and the nurses, from a natural wish to cultivate their own garden, have drawn away from the doctors. It will not do: any disunity—anything short of complete and sympathetic collaboration—means too much risk to the patient.

The neglect of nurses by the doctors has helped to bring nursing into disrepute with possible candidates Miss **MURIEL EDWARDS**, of the Nursing Recruitment Centre, tells us that when she talks in a girls' school on nursing as a profession she often has a long queue of eager questioners to answer at the end; but girl after girl says, "I want to do something in a hospital—not nursing, of course." Asked what, then, she would like to do, the girl says she would like to "do therapy." She does not know what kind of therapist she wants to be: she hardly understands the meaning of the word. All she knows is that a "massage" student is on a very different footing—not only with the doctors but with the general public—from a nurse. To her, nurses are hack workers of whom little scientific ability but much domestic work is expected; and unfortunately the lack of domestic help in hospitals has lately given fresh colour to this old prejudice. Theory in the present nursing curriculum, illogically based on the course of the medical student, is wide in scope and shallow in content, bewildering for the simple girl, yet leaving the girl with brains unsatisfied. Nursing should mean an intimate personal study of the patient; yet bedside nursing, the core of the whole art, is taught in hasty snatches by a sister who is fully occupied in other ways, and by a sister-tutor who is confined to the classroom, and must somehow invest an unresponsive dummy with the appeal of a living patient. Research in nursing is unknown under that name; for though many an ingenious sister contributes impromptu devices to nursing, there is no recognised way of spreading new methods from one hospital to another, and techniques which might have a universal value are stillborn, or live only as long as the local need persists. Again, nurses have no proper control over the equipment they use; these women, who should be as good with their hands and as thrifty with their strength as an old sailor, put up with much pointless exertion because a nurse is not expected to knock in nails, rig pulleys, or put screws in the ceiling when these would make things easier for the patient or for herself. The very aspect of nursing that should appeal most, alike to the intelligent and to the handy girl, has been allowed to sink into a hurried routine in which bedmaking and bedpans, the clock and the sister, have become dreary phantoms, crowding and diminishing the patient.

We believe that the medical profession must take a full and responsible share in restoring nursing to the position in which **FLORENCE NIGHTINGALE** placed it: as an absorbing and stretching career for women *with brains, as well as a satisfying occupation* for women who, though not academic, are physically and emotionally apt for the care of the sick. And we think that an important step in this reablement might be achieved by the founding of an experimental school of nursing in which new departures in the curriculum, as well as in the conditions of the nurse's life, might be given a fair trial. A large training hospital might offer the best opportunities for this venture, and it is possible that funds might be forthcoming from various sources to meet the expenses: certainly the Royal College of Nursing was in communication with the Rockefeller Foundation, before the war, about the establishment of a demonstration school of nursing, though this was probably dedicated to another type of experiment

In this school, we suggest, a medical dean of nursing should be appointed, to work with the matron, the sister-tutor, and the ward sisters in devising a theoretical curriculum oriented to the nurse's needs—for example, with less emphasis on anatomy and physiology and far more on bacteriology and spread of infection. The school might explore the possibilities of a two-year basic training for all entrants—in which bedside nursing was given the honourable place it deserves—and of a senior course, making good use of the mental capacities of the girl who wishes to become a sister. The medical dean of nursing should, in our view, feel himself or herself to be as much responsible for the proper training of the nurses as the dean of the medical school is for his students, and should bring his or her medical colleagues to share more fully in the education of student nurses, especially by taking ward rounds. An example of this kind could not fail to benefit the standing of nursing, besides renewing its standards.

The Bleeding Peptic Ulcer

THE treatment of gastroduodenal bleeding, in common with other hæmorrhagic conditions, has benefited from the war experience of blood-transfusion. This has brought home to the surgeon what large amounts of blood can and often should be given —one of **LOUTIT**'s[1] patients, for instance, received the equivalent of 17 litres in fifteen days. Moreover, administration has become technically easy and, with reasonable care, hæmatologically safe. The number of recognised agglutinins, it is true, is increasing, but their recognition has made it simpler to avoid the dangers of sensitisation. The amount of blood to be transfused must be based on the amount lost, but investigations on blood-volume in shock and hæmorrhage, initiated for gastroduodenal bleeding by Bennett and his collaborators [2] [3] before the late war, revealed the fallacies of clinical estimations of blood-loss. It is now clear that after hæmorrhage the fluid and corpuscular elements of the blood are restored to a certain extent independently of each other, and at completely different rates. The hæmoglobin level is therefore not in itself a reliable guide to the blood-loss; moreover, it is usually impossible to make any allowance for previous anæmia. The level is not immediately altered by a brisk and heavy bleeding, when corpuscles and plasma are lost in the same proportions; it is only later, when the plasma has been replaced and the patient's condition therefore improved, that the hæmoglobin, now lowered, gives some measure of the seriousness of the hæmorrhage. It is true that hæmodilution usually takes place within a very few hours, but it may take up to 24 hours,[2] and the picture is further complicated if the bleeding continues or recurs. The patient's general condition is of course important in estimating severity, and measurement of a large hæmatemesis or melæna will give a rough minimum estimate of the blood lost; the blood-pressure is also a valuable clue, particularly if the normal level is known, and a low pulse-pressure may help in the recognition of the collapsed hypertensive. Nevertheless, accurate criteria of severity are still lacking, and without them it is difficult to confirm and evaluate reports of treatment. What is most needed is an easy and reliable method of determining the blood-volume.

---

[1] Pappworth, M. H., Loutit, J. F. *Lancet*, 1943, ii, 469.

The controversy round treatment usually turns on whether the bleeding from chronic ulceration should be treated surgically or medically, and, if surgically, at what stage. Results are best where coöperation between physician and surgeon is closest.[4] Chronic ulceration accounts for 80% of cases of gastroduodenal hæmorrhage,[5] but where hæmatemesis or melæna is the first manifestation the differential diagnosis must be considered. The patient bleeding from an acute erosion or through cirrhotic congestion or a hæmorrhagic disease, such as purpura, is not a suitable subject for gastric exploration, though Finsterer [6] believes that when doubt exists the risk in operating is outweighed by the danger of leaving a chronic ulcer bleeding. He even advocates gastrectomy for the gastrostaxis of multiple erosions, though this is an extreme view and his quoted fatalities, whether operated on or not, by modern standards received woefully inadequate transfusions. On the other hand, his plea for operation on the known bleeding ulcer within the first 48 hours is well founded. Protracted hæmorrhage is to be anticipated from an ulcer with a big vessel open in its base; and though, if it is not too severe, the blood-loss can continually be made good, the patient's final condition, with very little of his own blood left, is not so satisfactory for operation as at the beginning. The bleeding often stops, thus dispelling the need to operate during the period of hæmorrhage; but sometimes it continues, and by procrastination the surgeon is finally offered a debilitated poor risk. The problem is to decide in which case the bleeding will stop. With a known or strongly suspected ulcer, if the bleeding is not appreciably lessening after 24 hours of adequate treatment it is wise to step up the transfusion until the hæmoglobin is at least 60%, and then take the patient to the theatre with the drip running. Where the diagnosis is in doubt, the best course is probably to replace blood for blood and to make every effort consistent with safety to establish a diagnosis. Some still say that transfusion, by raising the blood-pressure, will start hæmorrhage afresh. This is not supported by experience with drip methods, and indeed the bleeding sometimes stops as soon as the first pint has been absorbed. In any case it may be essential to raise the blood-pressure if life is to be saved.

Diet is important, whether the patient is being treated medically or surgically. A bland semi-solid diet, as recommended by Witts,[7] is perhaps the most generally useful. There is need to go slow with feeding for the first 24 hours; for the patients often feel sick, and vomiting is liable to start the bleeding again. Opinion is not yet settled as to the advisability of emptying the stomach of its blood contents with a tube; the smooth clot covered with mucus makes for nausea and interferes with the sealing of the bleeding vessel. After 72 hours, well-cooked cereals, custards, junket, soft-boiled egg, and puddings may be given in greater quantities. Vitamin C, up to 500 mg a day, should be given. Absolute bed rest may be supplemented by morphine, which should be given in moderate doses since these patients are prone to serious lung complications. Morphine should be replaced by barbiturates after 24 hours. In the convalescing patient the hæmoglobin and blood-pressure should be frequently estimated; the hæmoglobin should not be allowed to remain low, for a further hæmorrhage would then be disastrous. Packed corpuscles are at this stage superior to whole blood, and should be given in repeated small infusions.

When operation is decided on, its nature will obviously vary with the patient and the surgeon. To open the stomach (or duodenum) and insert mattress sutures over the ulcer is the simplest, and, with bad risks the best, procedure; and it may be necessary to combine this with ligature of the bleeding vessel. With the induration and distortion that is often present it may not be easy to establish which vessel needs tying or to expose it. Here detailed knowledge of anatomy is essential, and it should include an understanding of the anomalies of vessels at the pyloric end of the stomach which Gordon-Taylor [8] describes. He emphasises that operating for ulcer hæmorrhage is not synonymous with gastrectomy. The object is to stop the bleeding and prevent its recurrence; this may in fact be sometimes most readily attained by gastrectomy, and it is reasonable to consider this surgical cure if it does not add excessively to the risk. Some of the figures for gastrectomy show how remarkably results have improved with adequate transfusion—but it must not be forgotten that the results of medical treatment have also improved.

If the physician is to do his best for the patient he must learn to differentiate early between the case in which there is but a slow intermittent ooze and the serious hæmorrhage from the open large vessel, unlikely to yield to simple medical measures. The patients who die are usually those over the middle forties. This is not because of any associated arteriosclerotic brittleness of the vessels, but because these patients have almost certainly had ulcers of long standing; the bleeding vessel is encased in a fibrotic mass and is unable to retract and contract. Thrombosis in the vessel is the only hope of stemming the leak. The case with a long history, and particularly with previous bleeding, is the one where the need for surgery requires strongest consideration. Before the late war it was generally held that to operate after 48 hours' bleeding was nearly always disastrous, especially as the bowel suture lines seemed to make no attempt at adequate healing. With the adoption of massive rapid transfusions this is no longer true, and results in this country show that such "late" surgery is now being successfully undertaken. Nevertheless, cases requiring surgical intervention are relatively few, and medical management must still form the first line of treatment.

Infected Food

THE increasing incidence of food-poisoning since the start of the late war may be due, in part, to the growing number of residential institutions and communal feeding centres. Unfortunately, investigation of the toxic form is hampered by the lack of a susceptible animal. Moreover, no outbreak can be fully investigated unless it is notified at its very beginning; this rarely happens, and anyone working on the subject is familiar with the disappointment of arriving to find that all the suspected food has been thrown away or that only some empty tins remain, stinking and fly-blown after days in a dustbin. It is from the comparatively few outbreaks which have been fully investigated that our understanding of the condition is derived.

Ducks' eggs have been repeatedly incriminated as a source of salmonella infection. Lately *Salmonella typhimurium* (*aertrycke*) of identical phage type was isolated from a patient who had eaten an egg and from the duck itself[1]; and the Ministry of Health's war report[2] records altogether nine outbreaks from this source. MALLAM and ALHADEFF,[3] in recording another case, urged that ducks' eggs for eating should come from healthy birds, be gathered daily, and be laid in dry and uncontaminated surroundings. The hen's egg, in the "shell-egg" form, appears to be a rare source of infection; the first and only certain example was reported last year by WATT,[4] who isolated *S. montevideo* from eggs of the batch used for the mayonnaise from which an outbreak originated. However, *S. pullorum*, the cause of bacillary white diarrhœa, remains the most important source of fatal septicæmia in young poultry, and other salmonella organisms pathogenic to man are now causing serious epidemics in poultry. It was therefore natural that dried eggs, which began to arrive here in 1941 and were first distributed on a large scale in 1942, should be investigated for this group of organisms. Since 1942 there have, in fact, been outbreaks with many new types: to *S. typhimurium*, *enteritidis*, *thompson*, and *newport* have been added *S. oranienburg*, *montevideo*, *sundsvall*, *meleagridis*, and others hitherto unknown in this country. During 1942 vast numbers of American troops were arriving here; but, though they mixed with the civilian population, they took no part in the preparation of its food, and are thus unlikely to have had any notable effect. Investigation, in fact, confirmed that dried eggs were the source, for in them the new types, including *S. oranienburg* and *S. montevideo*, were identified. During the war altogether ten outbreaks of salmonella infection in man were attributed to this source,[5] although the instructions for reconstitution had been amended to direct that the fluid mixture should be used immediately, so as to minimise the time during which the organisms could multiply.

Cooked-meat products have always been regarded as an important cause of food-poisoning, especially because the salmonella group is pathogenic to both bovines and pigs; *S. dublin* and *S. enteritidis*, for example, are a cause of diarrhœa in cows and may give rise to symptoms in humans who drink infected milk. But cooked meat, particularly in brawn and meat pies, is probably most commonly infected from extraneous sources, such as food-handlers, rodents, or flies. The food is commonly harmless when eaten soon after being prepared, but, by the multiplication of bacteria in such an admirable medium, may cause serious illness when consumed a few hours later. Last year an extensive and explosive outbreak in three eastern States of the U.S.A. was traced[6] to cheese, which was found to contain *S. typhimurium* although it had been stored at 43°–48° F for 302 days after manufacture. Occasionally, outbreaks of food-poisoning have been attributed to members of the dysentery group; one such outbreak, probably due to infected ice-cream, occurred at Aberystwyth four years ago.[5] Whatever the causative organism, the clinical syndrome is usually much the same, with headache, upper abdominal cramps, nausea, diarrhœa, and sometimes vomiting and fever; recovery is complete within a week. With severe infection, particularly in the young and old, the symptoms are more varied, and meningitis, septicæmia, or an acute abdominal condition may be simulated.

The toxic form of food-poisoning is now well known in Britain. Of 296 outbreaks, the toxic products of bacterial growth were blamed in 115, injurious chemicals in 6, and salmonella organisms in 38. The clinical picture can hardly be mistaken: after a short incubation period, usually of about 4 hours, there is an acute onset, with vomiting, abdominal pain, and usually diarrhœa and prostration, which are followed

by rapid recovery. The commonest organism is the coagulase-positive *Staphylococcus aureus*, whose toxin is relatively heat-stable and may resist cooking; it may find its way into the food from handlers with minor septic hand infections or with heavy nasal infection. Outbreaks have been traced to other organisms, including non-hæmolytic streptococci, the proteus group, and various anaerobic bacilli, but no cases of *Clostridium botulinum* infection have been recorded in this country since 1936.

The existence of human carriers of the food-poisoning organisms has often been denied; but BURT[7] has described a patient who carried *S. typhimurium* for 4 years; and TOMLINSON and LINSELL[8] found that convalescents carried *S. thompson* for up to 6 weeks. Such people would be dangerous to others if they were in charge of food-preparation. Much can be done to prevent the disease by the education of kitchen staffs in personal hygiene and by suitable arrangements for the washing of hands and utensils. During the war cook-house personnel of the Army and R.A.F. were investigated for organisms of the salmonella group. If this simple investigation were extended to food-handlers in all the larger feeding centres, carriers could be identified and diverted to some less dangerous occupation.

Annotations

CRISIS AND CONSEQUENCES

THE crisis over the capitation fee, which endangered the chance of good relations between insurance practitioners and the Ministry of Health, has now been resolved. Up and down the country a great many doctors stood ready to resign from the National Health Insurance service at the call of the Insurance Acts Committee. The new approach came a fortnight ago from the Minister, who recognised no doubt how wide was the feeling of injustice created by his refusal of separate discussions on the application of the Spens report to the current capitation fee. As a result a formula has been reached which the I.A.C. is recommending the Panel Conference to accept. "The Minister," we are now told, "is willing fully to apply the Spens report to the current capitation fee with effect from Jan. 1, 1946, the increase of 2s. being regarded as a payment on account. To this end, he invites the I.A.C. to enter into discussions on the report forthwith, with special reference to the current capitation fee. The discussions will be conducted expeditiously."

No doubt the Panel Conference (which meets as we go to press) will find this proposal acceptable. It could hardly do otherwise, for the Minister has accepted without qualification the very demand made to him by the I.A.C.—failing acceptance of which, resignations were to be invited. That an agreement is within sight is good, and better still is the promise that discussions will be started at once and conducted expeditiously. It is to be hoped that an early and generous settlement can now be negotiated, that the long frustration which has marred relations with the Ministry will be removed, and that the way will thus be cleared for dispassionate consideration of the problems which will crowd upon us with the enactment of the National Health Service Bill.

Nevertheless the controversy now ending is bound to have repercussions when the time comes for asking members of the profession individually whether they favour discussion on the regulations to be made under the Act. Lest too easy conclusions should then be drawn, it would be well to record now, and to remember later, that the doctors have gained their point this time chiefly because they had a case, a good case, and one on which they felt genuinely united. It may be, too, that the Minister has been accommodating because the very reasonableness of the practitioners' case, and of its presentation by the I.A.C., placed him in a vulnerable position. In the larger issues shortly to be met the circumstances will be different. Lord Listowel, speaking for the Government in the House of Lords, expressly said: "We all desire the coöperation of the medical profession in working out the machinery for the new health service." Mr. Bevan, at the annual dinner of the British Orthopædic Association, reported on another page, remarked that his relations with the British Medical Association grow more friendly week by week, and that before very long, he is sure, they will reach a cordial understanding and obtain coöperation in carrying out the great work of the health service. We hope he is not being over-optimistic; and we believe the profession will accept his sincere desire to have full coöperation from its representatives in drafting the regulations which will shape the new service. It would be a mistake, however, to suppose that, with his health policy newly endorsed by both Houses of Parliament, he will be either willing or able to buy such cooperation by any deviation from the policy now expressed in the Bill. The profession will have much to gain by negotiating liberalising regulations under the Act when time and opportunity offer; but it will achieve nothing positive if its contribution takes the form of general condemnation and boycott of the new Act.

TRAINING IN CHILD WELFARE

THE education of girls has been modelled so closely on the education of boys that most girls leaving school at 16 or 18 have little experience of cooking, domestic management, or the care of children, and moreover have acquired an impression that time spent on such things is wasted. (Those who leave school at 14 may have a better chance of learning these basic arts, for they often come of larger and poorer families where it is natural for everyone to lend a hand.) Yet the care of children in the home, as we had occasion to say not long ago,[1] is at least as important as the care of the machine in a factory; and the output of the home takes precedence of the output of industry.

A group committee of the National Council for Maternity and Child Welfare have published a report[2] on courses of training in the care of healthy children of all ages, not only for students taking higher posts in children's homes and nurseries but also for teachers in the subject. They contemplate the development of a new profession of child welfare, having equal status with nursing and teaching. At present the only recognised training specifically for child care is the elementary course for the National Nursery Certificate, planned for girls between 14 and 16, and only dealing with children of nursery age. Those who wish to take responsible posts in nurseries or nursery schools must train, after the age of 18, as hospital nurses or nursery-school teachers; but a nurse's training, with its bias towards the care of sickness, is not the ideal background for holders of these posts, while nursery-school teachers concentrate mainly on children between the ages of 2 and 5 and learn nothing of the care of children under 2. The Curtis Committee on the care of children recently suggested[3] that there should be training for the house mothers and house fathers who take charge of residential foster homes, but this has yet to be started. In Scotland a new course for nursery workers is about to be instituted.[4]

Child welfare must be taught by good teachers; and these, the committee suggest, should be trained in child-welfare colleges—or departments of existing colleges—associated with a university, and especially with university departments of child health and education. They would also be associated with centres offering allied courses, such as teachers' and domestic-science colleges. Those intending to become teachers would take the full course, lasting three years, and those wishing to take posts in nurseries or children's homes would take a two years' course. They would study the child and his needs in relation to the family, including his physical, mental, and emotional development from infancy to adolescence. The course would cover nutrition, from breast-feeding to a full mixed diet, and clothing, from the layette to the dress of well-grown young people; there would be training in home management, lectures on existing social services in this country and others, practical work in nurseries, play centres, youth organisations, and residential homes, and instruction in he teaching of child welfare. A six months' course would also be provided for those who, having qualified n an allied profession—as teachers, nurses, or health visitors—wished to become child-welfare workers or teachers. The outlines of the syllabus are sketched in an appendix.

The second part of the report sets out plans for better instruction in child care in secondary schools and county colleges. A study of 77 infant deaths at Barnsley[5] shows that among 31 deaths classed as preventable, 19 were attributed to such interrelated factors as poor social and economic conditions, poor mothercraft, poor coöperation by the mother, and poor team-work by the hospitals or public-health staff. The committee believe that a gain in children's health, and ultimately that of the whole community, would be achieved if girls were given more instruction in child care—a view which we warmly share.

RHEUMATISM RESEARCH CENTRES

In 1945 the Ministry of Health's medical advisory committee recommended that a number of diagnostic and research centres should be established for the study of chronic rheumatism and for the improvement of diagnosis and treatment. The special centres, it was felt, should be located in university medical schools and teaching hospitals, and the Nuffield Foundation has now made a grant of £100,000, spread over ten years, towards the establishment of such a centre at the University of Manchester. There is to be, first, a diagnostic and research centre at the teaching hospital, the Manchester Royal Infirmary, to deal with short-stay inpatients and outpatients who will be referred from peripheral clinics in the region. For long-stay inpatients there will also be a clinic at a nearby base hospital, provided by the Manchester public-health committee, and a second base hospital in the country, the Devonshire Royal Hospital at Buxton. At these base hospitals lengthy investigations will be carried out and problems of reablement and resettlement will be studied. This scheme will ensure ready access to a very large number of cases, especially those in an early stage. At the centre the work will cover two main fields—the clinical, sociological, and industrial aspects of the disease, and the fundamental study of the rheumatic process. The clinical work will be directed by a physician, who will have the help of the departments of orthopædics and physiotherapy of the Manchester Royal Infirmary as well as of the university dental school. The social aspects of rheumatism, and its industrial implications, will be studied in coöperation with the university department of industrial health. Bone and joint pathology will be investigated under the direction of a pathologist expert in the subject. It is hoped that the scheme will lead to diffusion of the knowledge gained at the university centre.

Readers will recall that the British Legion recently set up a 50-bed rheumatism research and treatment centre at Fairfield Hospital, near Letchworth.[1] This is closely linked with the parent hospital in London, the Royal Free.

SULPHONAMIDE GRANULOPENIA IN CHILDREN

The effects of sulphonamide drugs on the blood-forming tissues are now well known—hæmolytic anæmias, agranulocytosis, and sometimes aplastic anæmia. The manifestations may be of an allergic type, appearing suddenly during a first or subsequent course of treatment; or they may be toxic in character, appearing gradually during the treatment. Menten and her associates[1] have been watching the effects in children and have noted that there have been far more cases of aplastic anæmia and neutropenia—short of agranulocytosis—in a children's hospital since sulphonamides became commonly used, particularly for infections of the upper respiratory tract and other infections, such as cellulitis. Aplastic anæmia is uncommon in childhood; only 1 case was seen in this hospital between 1928 and 1942 but there were 6 between 1942 and July, 1945. Of these 6 cases, 5 had received sulphonamide drugs shortly before the diagnosis was made, and the dose was often on the large side—over 30 g. in children of 6–13 years. All were fatal. Granulopenia shows a similar increase,[2] from 2·9% of admissions to the hospital in 1939 to 12% in 1944, the peak year; the 12% all had at some time less than 3000 granulocytes per c.mm., and about half of them had less than 2000 per c.mm. In 1945, when penicillin was beginning to replace sulphonamides, the incidence fell to 7·6%, but analysis of the cases showed that in 1944 and 1945 about 20% of all children receiving sulphonamides developed a definite granulopenia at some stage.

In animals with experimental granulopenia induced by sulphonamides it had been noted that folic acid would bring about, or at least accelerate, recovery of the blood-forming tissues. Menten and Graff[3] therefore treated some of their granulopenic children with folic acid. At first results were negative; because of favourable published reports pyridoxine was then added, 150 mg. being given by mouth daily. The effects were, on the whole, encouraging; 13 out of 22 children treated showed a rise of granulocytes towards normal levels; the rise was not rapid, most patients requiring treatment for a week to a fortnight. In some the blood-count relapsed when the treatment was stopped, and in some a further dose of sulphonamide produced a relapse. The 9 patients who did not respond—or only responded poorly—were all in hospital for upper respiratory infections; 3 had had treatment with folic acid alone for two or three days only (too short a period), 2 were taken home just when observations might have proved useful, and 4 showed no definite effect. To give folic acid and pyridoxine separately is expensive, and an attempt was made to get results by adding yeast to the diet; in practice the attempt failed because the yeast, either live or in powder, produced too much intestinal gas and abdominal distension.

Unfortunately no figures are available to show the speed of recovery of children whose sulphonamide drug was stopped—as it was in all cases—and who were given no other treatment; experience in adults suggests by rapid recovery. The commonest organism is the coagulase-positive *Staphylococcus aureus*, whose toxin is relatively heat-stable and may resist cooking; it may find its way into the food from handlers with minor septic hand infections or with heavy nasal infection. Outbreaks have been traced to other organisms, including non-hæmolytic streptococci, the proteus group, and various anaerobic bacilli, but no cases of *Clostridium botulinum* infection have been recorded in this country since 1936.

The existence of human carriers of the food-poisoning organisms has often been denied; but Burt[7] has described a patient who carried *S. typhimurium* for 4 years; and Tomlinson and Linsell[8] found that convalescents carried *S. thompson* for up to 6 weeks. Such people would be dangerous to others if they were in charge of food-preparation. Much can be done to prevent the disease by the education of kitchen staffs in personal hygiene and by suitable arrangements for the washing of hands and utensils. During the war cook-house personnel of the Army and R.A.F. were investigated for organisms of the salmonella group. If this simple investigation were extended to food-handlers in all the larger feeding centres, carriers could be identified and diverted to some less dangerous occupation.

Annotations

CRISIS AND CONSEQUENCES

The crisis over the capitation fee, which endangered the chance of good relations between insurance practitioners and the Ministry of Health, has now been resolved. Up and down the country a great many doctors stood ready to resign from the National Health Insurance service at the call of the Insurance Acts Committee. The new approach came a fortnight ago from the Minister, who recognised no doubt how wide was the feeling of injustice created by his refusal of separate discussions on the application of the Spens report to the current capitation fee. As a result a formula has been reached which the I.A.C. is recommending the Panel Conference to accept. "The Minister," we are now told, "is willing fully to apply the Spens report to the current capitation fee with effect from Jan. 1, 1946, the increase of 2s. being regarded as a payment on account. To this end, he invites the I.A.C. to enter into discussions on the report forthwith, with special reference to the current capitation fee. The discussions will be conducted expeditiously."

No doubt the Panel Conference (which meets as we go to press) will find this proposal acceptable. It could hardly do otherwise, for the Minister has accepted without qualification the very demand made to him by the I.A.C.—failing acceptance of which, resignations were to be invited. That an agreement is within sight is good, and better still is the promise that discussions will be started at once and conducted expeditiously. It is to be hoped that an early and generous settlement can now be negotiated, that the long frustration which has marred relations with the Ministry will be removed, and that the way will thus be cleared for dispassionate consideration of the problems which will crowd upon us with the enactment of the National Health Service Bill.

Nevertheless the controversy now ending is bound to have repercussions when the time comes for asking members of the profession individually whether they favour discussion on the regulations to be made under the Act. Lest too easy conclusions should then be drawn, it would be well to record now, and to remember later, that the doctors have gained their point this time chiefly because they had a case, a good case, and one on which they felt genuinely united. It may be, too, that the Minister has been accommodating because the very reasonableness of the practitioners' case, and of its presentation by the I.A.C., placed him in a vulnerable position. In the larger issues shortly to be met the circumstances will be different. Lord Listowel, speaking for the Government in the House of Lords, expressly said: "We all desire the coöperation of the medical profession in working out the machinery for the new health service." Mr. Bevan, at the annual dinner of the British Orthopædic Association, reported on another page, remarked that his relations with the British Medical Association grow more friendly week by week, and that before very long, he is sure, they will reach a cordial understanding and obtain coöperation in carrying out the great work of the health service. We hope he is not being over-optimistic; and we believe the profession will accept his sincere desire to have full coöperation from its representatives in drafting the regulations which will shape the new service. It would be a mistake, however, to suppose that, with his health policy newly endorsed by both Houses of Parliament, he will be either willing or able to buy such coöperation by any deviation from the policy now expressed in the Bill. The profession will have much to gain by negotiating liberalising regulations under the Act when time and opportunity offer; but it will achieve nothing positive if its contribution takes the form of general condemnation and boycott of the new Act.

TRAINING IN CHILD WELFARE

The education of girls has been modelled so closely on the education of boys that most girls leaving school at 16 or 18 have little experience of cooking, domestic management, or the care of children, and moreover have acquired an impression that time spent on such things is wasted. (Those who leave school at 14 may have a better chance of learning these basic arts, for they often come of larger and poorer families where it is natural for everyone to lend a hand.) Yet the care of children in the home, as we had occasion to say not long ago,[1] is at least as important as the care of the machine in a factory; and the output of the home takes precedence of the output of industry.

A group committee of the National Council for Maternity and Child Welfare have published a report[2] on courses of training in the care of healthy children of all ages, not only for students taking higher posts in children's homes and nurseries but also for teachers in the subject. They contemplate the development of a new profession of child welfare, having equal status with nursing and teaching. At present the only recognised training specifically for child care is the elementary course for the National Nursery Certificate, planned for girls between 14 and 16, and only dealing with children of nursery age. Those who wish to take responsible posts in nurseries or nursery schools must train, after the age of 18, as hospital nurses or nursery-school teachers; but a nurse's training, with its bias towards the care of sickness, is not the ideal background for holders of these posts, while nursery-school teachers concentrate mainly on children between the ages of 2 and 5 and learn nothing of the care of children under 2. The Curtis Committee on the care of children recently suggested[3] that there should be training for the house mothers and house fathers who take charge of residential at St. Joseph's Hospital, Winnipeg. The course, lasting a year, includes 3 months of classroom work and 9 months' experience in hospital, of which 1½ months must be spent in a tuberculosis sanatorium.

A course in Ontario, lasting 9 months, is divided into three equal parts, devoted to the classroom work, supervised practice in the hospital and community, and practical work in hospital on a small salary.

The *Canadian Hospital* for September, after surveying what has been done, raises a number of questions about possible developments. As regards legislation it is thought better to have one controlling Act dealing with all the nursing services than to follow the example of Manitoba. The risk of competition with registered nurses is not considered serious; even if there were a depression, there would be new openings for registered nurses. A suitable name has been much discussed, and "practical nurse" is definitely first favourite. The journal holds that this new grade is likely to be permanent.

BETWEEN TWO CENTURIES

THE first medical officer of health, Dr. W. H. Duncan, Liverpool, was appointed on Jan. 1, 1847; and is approaching centenary was the theme of Sir llen Daley's presidential address to the Society of ledical Officers of Health on Oct. 17.[1] He found uch to be thankful for. Contrasting the national tatistics of 1847 and 1945, he showed that, while the irth-rate declined from 31·5 per 1000 to 16·1, the death-ate fell from 24·7 to 11·4, infant mortality from 164 er 1000 live births to 47, and maternal mortality from ·52 to 1·84. Against the acute infectious diseases, to hich the public-health service has paid special attention, onsiderable success has been attained; but this does ot apply to all of them, and the increase of the tuberulosis death-rate early in the war showed the precariousess of our attack. Nor does Sir Allen think that the ncreases in the deaths from respiratory and circulatory iseases and from cancer can be lightly dismissed on the round that we must all die of something:

> "Many of these deaths are preventable in that they are curable if treated early. Very many, particularly the respiratory disorders, occur in young children. Coronary thrombosis carries off many of our most able citizens in middle age. Death from rheumatic carditis can be largely reduced, if not prevented. Cancer is a serious cause of death well before the age of 65. It is gratifying that increasing attention is now being given to gerontology, or the study of old age, and its causes, but we must recall Professor Crew's words: the real problem is not 'how to give years to life but life to years.'"

Unfortunately, continued the president, the M.O.H. still does not possess the tools needed for his job: he ought to have complete morbidity figures for his own area, and, if it is large, for the various sections of it. In the future every doctor must be imbued with the principles of preventive medicine, asking himself, for each patient, "Why is he ill? Could this illness have been prevented? If so, how?" Before very long there will no longer be the two camps of curative and preventive medicine, for all who look after patients will combine curative and preventive work. Nevertheless there will always be room for the specialist in preventive medicine, and his rôle will be increasingly important, covering communal hygiene, industrial hygiene, epidemiology, the care of the convalescent and the disabled, the teaching of health, and administration. At the health centre "we will have administrative duties in which we are all well trained. The duty of an administrator is to ensure that the proper tools, auxiliary staff, and accommodation are provided for the executives to do the job." Freedom from the pressing cares of managing a hospital service will give the M.O.H. more time to develop his functions as a specialist in preventive medicine.

At the beginning of their second century, Sir Allen Daley called on his hearers to carry on the torch of preventive medicine, which should illuminate with increasing strength the whole medical field.

ANÆSTHESIA IN RETROSPECT

THOUGH a hundred years have passed since Robert Liston operated under ether, we should not, in celebrating this memorable centenary, ignore many earlier successes. Prof. Charles Singer, who took the chair at the Royal Society of Medicine's meeting on Oct. 16, had the agreeable task, fulfilled with elegance, of reminding those present of Adam, of the anæsthetic sponge, of mandragora, henbane, and prickly lettuce, of mesmerism, of Boccaccio's *Decameron* (suitably expurgated), and of the poet Southey's view that the atmosphere of the very highest heaven is composed of laughing gas. Dr. Barbara Duncum, who had the more mundane duty of outlining the development of inhalation anæsthesia in the second half of the nineteenth century, contributed solid facts to an informative afternoon. The modern development of anæsthesia was confided to Dr. Joseph Blomfield, who told of the year 1900 when we had chloroform, ether, and nitrous oxide and nothing else; of ethyl chloride, useful for short operations on children; of open ether ("some of you may even have given it"); of spinal anæsthesia; of Knapp's venous congestion, rectal ether, oral chloroform given with paraffin and followed by half a glass of port; of premedication, endotracheal ether, intravenous anæsthetics, and many another technical advance or experiment.

At the end of the meeting Dr. E. Ashworth Underwood startled the company with an original piece of research, bringing strong evidence to show that Liston's famous amputation was not the first operation in Europe to be done on a patient under general anæsthesia, but that two surgeons in his native town of Dumfries, at the instigation of a fellow Scot, Dr. James Fraser, had quietly performed an amputation on an etherised patient about a month or six weeks before Liston got round to his. Fraser knew Morton in America, and when he came home on a visit he seems to have persuaded Dr. McLaughlin and Dr. Scott, at the Dumfries Infirmary, to try sulphuric ether on a patient with a fractured limb—probably some time in November, 1846. Liston, of course, did his operation on Dec. 21, 1846.

This painstaking piece of historical research, which seems likely to carry the priority honours from England to Scotland, was unfortunately delivered at the end of the session to a closely packed hall whose atmosphere was itself somewhat anæsthetic. More justice was done to it, however, at the Wellcome Historical Medical Museum, where an exhibition on the history of anæsthesia was opened by Lord Moran later in the afternoon. Here some of the relevant documents were well displayed, together with early works on analgesics, and many types of inhaler used in early experiments. The case for the patient, too, has been generously included in the form of a song, to be sung to an air from "The Beggar's Opera," which appeared in the *Illustrated London News* of Jan. 30, 1847:

How happy could I be with Æther
  Were mesmeric charmers away,
But while they perplex me together
  The Devil a word can I say.
Sing Robinson, Thomson, and Cooper,
  Fol Lol de Rol, Lol de Rol, Lay
There's nothing like Æther and Stupor
  For making a hospital gay.

WE have to record that Dr. T. WARDROP GRIFFITH, emeritus professor of medicine in the University of Leeds, died on Oct. 21. He was in his 86th year.

---

[1] To appear in full in the November issue of *Public Health*.

that the recovery would not be much less rapid than in the patients treated with folic acid and pyridoxine. Neither of these substances is easy to obtain in this country, but the combination is clearly worth a trial in persistent cases of granulopenia. Menten's observations remind us that toxic depression of hæmopoiesis is a factor to be reckoned with when using sulphonamides in children's diseases.

THE DEMOBILISED SPECIALIST

THE last few months before demobilisation is for many medical officers an anxious period, filled with questioning about their civilian prospects. Of those who want to be specialists, some already have the qualifications and experience expected of applicants for senior civilian appointments; but even for these the way has not been easy. Registrarships, supernumerary or otherwise, have offered a temporary refuge; but the number of posts offering a livelihood to fully qualified specialists has been far below that of the suitable candidates. At any time there would have been some delay before all these men were absorbed; but the extent and the duration of unemployment and uncertainty have been magnified because most young specialists now expect to receive a substantial proportion of their income from a hospital, while the hospitals are disinclined at present to enter into new commitments.

Some months ago the Minister of Health showed himself alive to these circumstances by encouraging hospitals to create new senior paid appointments, and he promised to come to their rescue if they should get into financial difficulties. Perhaps judging its terms to be too vague, the hospitals showed themselves somewhat unresponsive to this appeal. Now Mr. Bevan has intervened again with an unequivocal offer: local authorities and the larger voluntary hospitals are invited to increase their senior establishments by creating additional whole-time posts, at salaries of about £1000 a year, the cost of which is to be charged to the Treasury. The Minister also proposes to ease the lot of the junior specialist by increasing the number and the duration of supernumerary registrar appointments, and he has made the important concession that these appointments shall be open also to those who were specialists in the Forces, though they had not previously shown an intention to specialise. The continued training of graded specialists is still under discussion; the usual practice at the moment is for them to spend six months in a grade I appointment before being advanced to registrar status. These fresh concessions, the need for which we stated last June,[1] will prevent many from drifting, through economic necessity, into other fields, where they would be lost to specialist practice; and it has doubtless not escaped the Minister that those who benefit under this scheme will form a useful nucleus when the new service, with its unprecedented demand for specialists, begins to operate.

What of the future general practitioner? The only word the Minister spares for him is that a grade I appointment will be provided as soon as possible after demobilisation. Nevertheless, the general practitioner, no less than the specialist, has his problems, some of which we have already indicated.[2] They include the difficulty, if he takes a grade I appointment, of managing his affairs on the salary of a senior houseman; the scarcity of assistantships; the reluctance of principals to accept new partners or to sell their practices; and the heavy responsibility of investing capital in a house or practice, if one can be found. Possibly doctors with panel practices may be more ready to employ assistants now that the capitation fee is likely to be further raised; but even given an assistant's salary the man with family responsibilities may still wonder how to make ends meet.

ENCEPHALOMENINGITIS OF VIRUS ORIGIN

SOONER or later most practising doctors come across the healthy young patient who, after a few days' headache and malaise, falls acutely ill with fever, headache, drowsiness or even stupor, and meningism, with or without increased tendon reflexes and an extensor plantar response. The first sigh of relief is expressed when the chloride content of the cerebrospinal fluid is found to be normal; and the next when the fluid, which may be clear or only faintly opalescent, is proved to contain no organisms. The cells—mostly lymphocytes—number up to 200 per c.mm., and there is a slight increase in protein. At the end of a week or so the temperature falls, the patient embarks on the road to convalescence, and the doctor's bewilderment is forgotten in his relief that the condition, whatever it may have been, has left no mark.

Even the elect may find it impossible to explain such an illness. Acute encephalitis lethargica, poliomyelitis, and acute lymphocytic choriomeningitis must all be borne in mind during the early days, but the truth seems to be that this clinical picture can be produced by a large variety of viruses, some of which usually, and some only rarely, attack the nervous system. In addition to those mentioned these include lymphogranuloma venereum, psittacosis, infectious mononucleosis, and mumps. St. Louis encephalitis and the two varieties of equine encephalitis have so far only been observed in the United States. Doubtless other hitherto unidentified viruses may also be the cause. Instances of this syndrome are constantly occurring sporadically, and are seldom diagnosed until recovery or complications set in.

Since June a good many examples of an illness of this kind have been seen in the London area. The characteristics of this particular outbreak are its scattered distribution and the rarity with which two members of the same family are affected; observation has been complicated by a concurrent outbreak of poliomyelitis. In some patients cranial nerve palsies have been recorded, but fortunately recovery from these as from the other manifestations has almost always been complete. Little new light has been thrown on the ætiology, though there is renewed suspicion that the infection may be transmitted through animals, including such domesticated creatures as the cat. Many of these neurotropic viruses have been shown to infect animals or birds, from which they may be transmitted to man by insect vectors such as mosquitoes or ticks.

PRACTICAL NURSES IN CANADA

IN 1945 the Province of Manitoba passed an Act to authorise "the training, examination, licensing, and regulation of practical nurses." The Act defined a practical nurse to be "a person who being neither a registered nurse nor a person in training to be a registered nurse at a school of nursing recognised by the Minister undertakes nursing for remuneration." With the approval of a qualified medical practitioner, a licensed practical nurse may perform nursing duties "(a) during the convalescence of a patient, (b) after childbirth where there are no complications necessitating the services of a registered nurse, (c) in mild types of illness, (d) in chronic illness of long duration not requiring the services of a registered nurse, or (e) in any other cases prescribed in the regulations."

The council entrusted with the administration of the Act contains representatives of the Manitoba Association of Registered Nurses and anticipates the formation of an association of practical nurses who will also be represented on it. The aid of the various organisations of registered nurses throughout the Dominion has been enlisted, and instruction of practical nurses is being carried out under their direction. The first class for practical nurses was opened at the beginning of the year at St. Joseph's Hospital, Winnipeg. The course, lasting a year, includes 3 months of classroom work and 9 months' experience in hospital, of which $1^1/_2$ months must be spent in a tuberculosis sanatorium.

[2] *Ibid*, p. 968.

A course in Ontario, lasting 9 months, is divided into three equal parts, devoted to the classroom work, supervised practice in the hospital and community, and practical work in hospital on a small salary.

The *Canadian Hospital* for September, after surveying what has been done, raises a number of questions about possible developments. As regards legislation it is thought better to have one controlling Act dealing with all the nursing services than to follow the example of Manitoba. The risk of competition with registered nurses is not considered serious; even if there were a depression, there would be new openings for registered nurses. A suitable name has been much discussed, and "practical nurse" is definitely first favourite. The journal holds that this new grade is likely to be permanent.

BETWEEN TWO CENTURIES

THE first medical officer of health, Dr. W. H. Duncan, of Liverpool, was appointed on Jan. 1, 1847; and this approaching centenary was the theme of Sir Allen Daley's presidential address to the Society of Medical Officers of Health on Oct. 17.[1] He found much to be thankful for. Contrasting the national statistics of 1847 and 1945, he showed that, while the birth-rate declined from 31·5 per 1000 to 16·1, the death-rate fell from 24·7 to 11·4, infant mortality from 164 per 1000 live births to 47, and maternal mortality from 4·52 to 1·84. Against the acute infectious diseases, to which the public-health service has paid special attention, considerable success has been attained; but this does not apply to all of them, and the increase of the tuber-ulosis death-rate early in the war showed the precariousness of our attack. Nor does Sir Allen think that the ncreases in the deaths from respiratory and circulatory diseases and from cancer can be lightly dismissed on the ground that we must all die of something:

> "Many of these deaths are preventable in that they are curable if treated early. Very many, particularly the respiratory disorders, occur in young children. Coronary thrombosis carries off many of our most able citizens in middle age. Death from rheumatic carditis can be largely reduced, if not prevented. Cancer is a serious cause of death well before the age of 65. It is gratifying that increasing attention is now being given to gerontology, or the study of old age, and its causes, but we must recall Professor Crew's words: the real problem is not 'how to give years to life but life to years.'"

Unfortunately, continued the president, the M.O.H. still does not possess the tools needed for his job: he ought to have complete morbidity figures for his own area, and, if it is large, for the various sections of it. In the future every doctor must be imbued with the principles of preventive medicine, asking himself, for each patient, "Why is he ill? Could this illness have been prevented? If so, how?" Before very long there will no longer be the two camps of curative and preventive medicine, for all who look after patients will combine curative and preventive work. Nevertheless there will always be room for the specialist in preventive medicine, and his rôle will be increasingly important, covering communal hygiene, industrial hygiene, epidemiology, the care of the convalescent and the disabled, the teaching of health, and administration. At the health centre "we will have administrative duties in which we are all well trained. The duty of an administrator is to ensure that the proper tools, auxiliary staff, and accommodation are provided for the executives to do the job." Freedom from the pressing cares of managing a hospital service will give the M.O.H. more time to develop his functions as a specialist in preventive medicine.

At the beginning of their second century, Sir Allen Daley called on his hearers to carry on the torch of preventive medicine, which should illuminate with increasing strength the whole medical field.

ANÆSTHESIA IN RETROSPECT

THOUGH a hundred years have passed since Robert Liston operated under ether, we should not, in celebrating this memorable centenary, ignore many earlier successes. Prof. Charles Singer, who took the chair at the Royal Society of Medicine's meeting on Oct. 16, had the agreeable task, fulfilled with elegance, of reminding those present of Adam, of the anæsthetic sponge, of mandragora, henbane, and prickly lettuce, of mesmerism, of Boccaccio's *Decameron* (suitably expurgated), and of the poet Southey's view that the atmosphere of the very highest heaven is composed of laughing gas. Dr. Barbara Duncum, who had the more mundane duty of outlining the development of inhalation anæsthesia in the second half of the nineteenth century, contributed solid facts to an informative afternoon. The modern development of anæsthesia was confided to Dr. Joseph Blomfield, who told of the year 1900 when we had chloroform, ether, and nitrous oxide and nothing else; of ethyl chloride, useful for short operations on children; of open ether ("some of you may even have given it"); of spinal anæsthesia; of Knapp's venous congestion, rectal ether, oral chloroform given with paraffin and followed by half a glass of port; of premedication, endotracheal ether, intravenous anæsthetics, and many another technical advance or experiment.

At the end of the meeting Dr. E. Ashworth Underwood startled the company with an original piece of research, bringing strong evidence to show that Liston's famous amputation was not the first operation in Europe to be done on a patient under general anæsthesia, but that two surgeons in his native town of Dumfries, at the instigation of a fellow Scot, Dr. James Fraser, had quietly performed an amputation on an etherised patient about a month or six weeks before Liston got round to his. Fraser knew Morton in America, and when he came home on a visit he seems to have persuaded Dr. McLaughlin and Dr. Scott, at the Dumfries Infirmary, to try sulphuric ether on a patient with a fractured limb—probably some time in November, 1846. Liston, of course, did his operation on Dec. 21, 1846.

This painstaking piece of historical research, which seems likely to carry the priority honours from England to Scotland, was unfortunately delivered at the end of the session to a closely packed hall whose atmosphere was itself somewhat anæsthetic. More justice was done to it, however, at the Wellcome Historical Medical Museum, where an exhibition on the history of anæsthesia was opened by Lord Moran later in the afternoon. Here some of the relevant documents were well displayed, together with early works on analgesics, and many types of inhaler used in early experiments. The case for the patient, too, has been generously included in the form of a song, to be sung to an air from "The Beggar's Opera," which appeared in the *Illustrated London News* of Jan. 30, 1847:

How happy could I be with Æther
  Were mesmeric charmers away,
But while they perplex me together
  The Devil a word can I say.
Sing Robinson, Thomson, and Cooper,
  Fol Lol de Rol, Lol de Rol, Lay
There's nothing like Æther and Stupor
  For making a hospital gay.

WE have to record that Dr. T. WARDROP GRIFFITH, emeritus professor of medicine in the University of Leeds, died on Oct. 21. He was in his 86th year.

THE SPIRIT IN WHICH WE WORK

THOUGHTS ON ST. LUKE'S DAY *

Sir ALFRED WEBB-JOHNSON, Bt.

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS

It is the tradition of our calling that the poorest and humblest has just as great a claim on our services as the highest and most affluent. The measure of their need is the measure of our help. Thus it was that Sir Frederick Treves, when his Sovereign, King Edward VII, thanked him for his life-saving attentions, was able to reply with pride: "Sir, you have had as much care and skill in your illness as the humblest of your subjects."

Such is the service that it is our privilege and duty to render, but we have been only too conscious of the limits of our ability—limits imposed by lack of adequate facilities. We have known that there were serious gaps in our service, and have realised that those gaps could only be filled with the help of the State.

The State is about to take a great part in British medicine. This is not surprising, for medicine is of wholly unique importance for the very existence of social life. But, "as the master builder must care for the whole building—so he that undertaketh to set it out (and use it) must seek out fit things for the adorning thereof." This will be our special and immediate task. We must first ensure that the conditions of service are such as to allow intellectual freedom, and to give character as much chance as cleverness. We must avoid the development of Molière's type of doctor, who thought it more honourable to fail according to rule than to succeed by innovation.

We must guard against uniformity, for the highest products of the human mind are the outcome of freedom and variety rather than of uniform organisation. Independence, which inspires fearless advice, must be preserved. In fact, if any of the essential freedoms of a great profession are threatened, then, in the interests of the people, there must be revision of the plan. Even when a system has been formed there may still be much to add, to alter, and to reject.

A PERSONAL SERVICE

The doctor's work is primarily a personal service, and his calling exacts the utmost that man can give—full knowledge, exquisite judgment, and skill in the highest, to be put forth, not at any self-chosen moment, but daily at the need of others. But illness is essentially a personal event. It consists of the individual himself. The patient is not limited by his outer covering. His surface is not his real frontier. A man may be more interested in his environment than in his own body. His position in the community or some work to which his passion drives him may appear to be of more importance than life itself. Thus it is that the family doctor has often to be his patient's confidant and friend, for, as Francis Bacon said: "No receipt openeth the heart but a true friend to whom you may impart griefs, joys, fears, hopes, suspicions, counsels and whatsoever lieth upon the heart to oppress it."

Then again, in Trotter's words, "the well-equipped clinician must possess the qualities of the artist, the man of science, and the humanist, but he must exercise them only in so far as they subserve the getting well of the individual patient." He must feel directly responsible *to* his patient, not *for* him—to someone else. It is a hard doctrine, but none the less true, that this essential function of the doctor—the care of the given patient—may involve the forgoing of exactly scientific diagnosis, of the artistic perfecting of an operation, or even of the interests of society at large. In his care for the individual the method of the doctor is so different from that of Nature:

> "So careful of the type *she* seems,
> So careless of the single life."

Those of us whose work lies in the hospitals must be prepared for changes under a new organisation. We must see to it, however, that we carry into the national hospitals the same spirit which inspired us in the great voluntary hospitals. There we learned to scan gently our brother man—judging not, asking no questions, but meting out to all alike a hospitality worthy of the Hôtel-Dieu, and deeming ourselves honoured in being allowed to act as its dispensers.

We must keep the souls and individuality of our hospitals alive, for hospitals are human institutions. No rigid plan, without margin or elasticity, will suffice or succeed. Above all, the State must not try to control development too strictly, for hospitals are also scientific institutions, and the essence of science is change.

MORAL RESPONSIBILITIES OF SCIENCE

We are vitally concerned with the application of scientific discoveries for the benefit of mankind. In our own time inventions and developments have followed each other fast as falling leaves, and the great blessing is that the leaves from the tree of science have been largely for the healing of the people. Advances have been achieved by the method of experiment—the method which, beyond all shadow of doubt, is the most effective implement for the advancement of knowledge ever invented by man. Moreover, it satisfies man's inveterate instinct not to confide his weight to a branch until he has tested it.

The greatest discovery in modern medicine is the detection of the minute bodies which cause many diseases, and the means by which they are carried. We now know that the carriers of many death-dealing diseases are not angels or demons, messengers of wrathful gods, but common things like flies, mosquitoes, lice, and fleas. We have but lately realised that we may be able to control or destroy these winged vectors of disease. Millions on millions of lives could be saved and the morale of native peoples raised by the prevention of malaria alone.

The millions that are saved must be fed. They must be reckoned with. This will be a problem for future generations—our task and duty are clear. As Carlyle wrote: "Let a man do his work; the fruit of it is in the care of Another than he." And again: "it is not thy works, which are all mortal, infinitely little, and the greatest no greater than the least, but only the spirit that thou workest in, that can have worth or continuance."

That is the point—*the spirit that thou workest in*. Scientific discoveries are powers for evil as well as for good. Is it not time that we decided that their use for the wholesale and indiscriminate destruction of human life should be outlawed? It is not only physical and chemical knowledge that can be misapplied, for biological discoveries might also be used for bacterial warfare. Is it not more in accord with our traditions and ideals to follow the example of Jenner, who, when England and France were at war, sent Woodville to Paris to help to control an epidemic of smallpox which was raging in the French capital! To commemorate this humanitarian action there stands at Boulogne today a statue to Jenner inscribed: "À Edward Jenner—La France Reconnaissante."

It may be that Man is at the cross-roads. Will he proceed higher and further, or will he bring about the catastrophic ending of the whole human story? Will he be swept aside by the Great Creator as an experiment that has failed? It is for man to decide his own fate

---

* Part of an address delivered in Liverpool Cathedral on Oct. 20, 1946.

His further and higher development depends on his own conscious efforts.

As more and more secrets are wrested from Nature we realise more and more clearly that there is no real conflict between faith and science. The laboratory can satisfy many of our needs, but not those of the spirit, so:

> "Let knowledge grow from more to more,
> But more of reverence in us dwell."

Belief is the healthy act of a man's mind. And does ot every true man feel that he is himself made higher y doing reverence to what is really above him?

In order to realise the moral responsibilities of science e must look to something higher, and something beyond ir own little lives. We must turn our minds to things hich have immortality. We inherit ideas and teachings hich are imperishable and everlasting.

Our best works are inspired by the thought that we are aking a contribution to the good of our successors, or to e advancement of ideas, institutions, and causes which ave continuity and permanence. As Lord Balfour said, t the end of a long life of public service: "By so much s we give of ourselves, our labour, and our loyalty to hings which have immortality, by so much shall we ncrease the joy of life and remove the sting from death."

OCTORS IN GOVERNMENT DEPARTMENTS

UNIFIED SALARY SCALES

THE different Ministries have hitherto had different cales of pay for doctors in their employ. With effect rom the beginning of this year these scales have now been nified in Government departments generally and also in he principal health departments, including the Ministry f Health, the Ministry of Education, the Ministry of abour, the Department of Health for Scotland, the Velsh Board of Health, and the Board of Control. Ve understand that the whole subject of salaries for edical staffs in Government departments may again be eviewed when the remuneration of other doctors participating in the National Health Service has been settled. Ieanwhile the scales for London will be:

GENERAL SERVICE.—*Medical Officer*, £1000 on entry at ge of 35, with annual increases of £30 to £1300, and thence y £50 increments to £1400. (The starting salary is reduced y £30 for each year of age under 35, and increased by £30 or each year of age over 35, up to 40.) *Principal Medical fficer*, £1400, with annual increases of £50 to £1600. *Director*, 1600, with annual increases of £50 to £1800.

HEALTH DEPARTMENTS.—*Medical Officer*, £1150 on entry t age of 38, with annual increases of £30 to £1300, and hence by £50 increments to £1500. (The starting salary is educed by £30 for each year of age under 38, and increased y £30 for each year of age over 38, up to 40.) *Senior Medical fficer*, £1500, rising annually by £50 to £1700. *Principal edical Officer*, £1600, rising annually by £50 to £1800.

NOTE.—In the Ministry of Health, since changes were ade a few months ago (*Lancet*, 1946, i, 932), the grade of edical officer has included those engaged in the health ervices and the regional and deputy regional medical officers n the insurance service. The grade of senior medical officer includes the former principal regional medical officers, the insurance divisional medical officers, and certain former senior medical officers. Two of the posts of principal medical officer (insurance and epidemiology) at present carry salaries of £2000, without increments. The new arrangements make certain provisions for safeguarding the "expectations" of doctors already in Government service.

In about a dozen large provincial towns the London standard rates as set out above will be reduced by £40 per annum on salaries up to £1300, and by £50 on salaries above that figure. Elsewhere in the provinces he deductions will be £80 and £100 respectively. Under present arrangements most of the more senior appointments in the health departments are in London.

The scales apply equally to men and to women.

BRITISH ORTHOPÆDIC ASSOCIATION

MINISTERS AS GUESTS

A DINNER held in London on Oct. 18 in connexion with the association's annual meeting, was attended by the Prime Minister, the Minister of Health, the Minister of National Insurance, and a number of overseas guests.

Sir HENEAGE OGILVIE, proposing The Association, outlined the rapid progress of orthopædics from the time, not so long ago, when its exponents had been an oppressed minority. Mr. GEORGE PERKINS, replying as president, avowed the need in each region for orthopædic centres, which should be centrally directed by a consulting orthopædic surgeon; there should also be a large orthopædic teaching centre, under a full-time staff. Salaries should be sufficient not only to attract good men but to enable orthopædists to visit other clinics.

Sir REGINALD WATSON-JONES, who proposed The Guests, welcomed, among others, Dr. Henry Meyerding (U.S.A.), the new president of the International Orthopædic Association, and Prof. E. Sorrel (Paris). He thought it time to end the anomaly by which the man who breaks his leg on Saturday afternoon receives less compensation than he would for the same injury sustained at work on Saturday morning; compensation is, he said, the community's responsibility and should be uniform. He declared himself against controls, preferring the wild English rose to ordered rows of cultivated tulips.

Mr. C. R. ATTLEE, in his reply, said that "we have to be careful today, when our man-power position is as acute as it was in time of war, that we do not waste our population, either by leaving unremedied remediable disabilities, or allowing the unnecessary creation of disabilities"; and he looked very much to the work and influence of the orthopædic surgeon. The National Health Service Bill would be placed on the statute-book by Parliament, but its implementation depended on the whole population. The happiest people, he suggested, quoting the example of Denmark, are to be found in the most equalitarian countries. "We do not want to see people regimented; but I believe just as in a good army, without loss of discipline, there is scope for initiative and energetic action by individuals, so in all our health activities there will be freedom, but freedom on an ordered plan of coöperation."

Mr. ANEURIN BEVAN contrasted the acrimony among politicians with the harmony between doctors. Each branch of medicine, he had noticed, considered the others to be its superior. "Members of the Royal College of Physicians emerge flushed with enthusiasm for the Royal College of Surgeons; and fellows of the Royal College of Surgeons regret there is not room for their college in Trafalgar Square"; specialists were concerned for the general practitioners, and general practitioners for the specialists. "The most eloquent politicians in Great Britain are to be found in the medical profession. Indeed, I've been learning quite a few tricks in the last year or two, and I hope to use them for the benefit of the medical profession." The politician's duty was to universalise the best. He had seen men suffer because they did not have the benefit of existing knowledge: "the specialist is not always available when he is needed." The health service must be organised in the most effective manner. "It is not my task to stand between the doctor and his patient. It is the task of the public-health services to put the best kind of medical apparatus in the hands of the profession, and it is for the profession to use it freely and independently for the benefit of their patients. . . . I am happy to say that enthusiasm grows. My relations with the British Medical Association grow more friendly week by week. Before long I am quite certain that we shall reach a cordial understanding and obtain coöperation in carrying out this great work."

Mr. JAMES GRIFFITHS said that insufficient attention had been given to the Industrial Injuries Act which had taken the injured person out of the grip of the employer; in its field, it was the best thing for half a century. Miners, he said, deserve special recognition, for among them occur half the country's industrial injuries.

LONDON'S VOLUNTARY HOSPITALS

THE continued practical interest of the public in the voluntary hospitals of London during 1945 is well demonstrated in the Annual Statistical Summary for that year just published by the King's Fund.[1] Despite a decrease of £67,000 in the income from public authorities, the total maintenance income of the 164 hospitals reached a record figure of £6,879,000; in addition £156,000 was given for endowment and £439,000 for building and equipment, making a grand total of £7,474,000, or £523,000 more than in 1944.

Income from subscriptions and donations rose by £135,000 to £1,276,000; patients' contributions by £227,000 to £1,120,000; and contributory schemes by £175,000 to £912,000. Legacies, a source of income which many predicted would suffer as the result of death duties, high taxation, and other adverse economic conditions, rose by £121,000 to £676,000. If "free legacies" are included, no less than 74·5% of the total maintenance income came from sources other than public authorities. Maintenance expenditure amounted to £6,466,000, or £625,000 more than in 1944, leaving a surplus for 1945 of £413,000.

The number of new inpatients rose from 206,000 to 236,000, and the average number of beds occupied daily from 10,447 to 12,797. The number of new outpatients was 1,641,000 and the number of outpatient attendances 7,888,000.

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED OCT. 12

Notifications.—Smallpox, 0; scarlet fever, 1106; whooping-cough, 1362; diphtheria, 269; paratyphoid, 6; typhoid, 3; measles (excluding rubella), 2005; pneumonia (primary or influenzal), 351; cerebrospinal fever, 37; poliomyelitis, 22; polio-encephalitis, 1; encephalitis lethargica, 1; dysentery, 44; puerperal pyrexia, 156; ophthalmia neonatorum, 69. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on Oct. 9 was 835. During the previous week the following cases were admitted: scarlet fever, 59; diphtheria, 22; measles, 13; whooping-cough, 35.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (1) from enteric fever, 1 (1) from measles, 12 (0) from whooping-cough, 5 (0) from diphtheria, 44 (2) from diarrhœa and enteritis under two years, and 9 (3) from influenza. The figures in parentheses are those for London itself.

There were 4 fatal cases of whooping-cough at Manchester. Liverpool and Manchester each reported 6 deaths from diarrhœa and enteritis.

The number of stillbirths notified during the week was 258 (corresponding to a rate of 26 per thousand total births), including 35 in London.

[1] Statistical Summary for 1945: King Edward's Hospital Fund for London, 10, Old Jewry, E.C.2. Pp. 62. 1s. (1s. 6d. post free).

MIDWIVES' PAY

EMPLOYING authorities have been advised by the Ministry of Health to adopt new recommendations by the Midwives Salaries Committee. These include a special service allowance of £20 at the end of each year's full-time employment for all (other than pupil) midwives. It is hoped that this grant may encourage more women who have the necessary qualifications to practise. The committee has now completed its review of all salaries. Under the revised scale a matron of a maternity hospital with 100–199 beds will receive a salary (inclusive of emoluments) ranging from £550 to £750, compared with the old range of £450 to £650; and a new inclusive salary ranging from £600 to £825 is recommended for matrons of institutions with 200 or more beds. Corresponding increases are recommended for matrons of the smaller hospitals and homes; and assistant matrons in institutions with 50 or more beds will now receive £410 to £485. Resident district midwives will now have a salary of £290 to £380, compared with the former £240 to £300. The committee has also recommended that part-time midwives should be given credit for years of previous service; and employing authorities are given discretion to increase the appropriate salaries by 10%.

In England Now

A Running Commentary by Peripatetic Correspondents

THE fact that hard-working G.P.s are given the task of allocating the nation's milk is certainly not an inducement to take up medicine. True, we are given a list of deserving cases entitled to extra milk, and on the face of it our task is easy. A pregnant woman gets her 1½ or 2 pints daily; so do sufferers from G.U. or T.B. That we can understand, but here comes the rub. Why does a man with a broken arm, being "an active worker on the panel," get his daily pint while our edentulous old dears in the 80's get nothing extra? Questions like this are unanswerable. Of course, we may stretch a point and give an occasional pint under the all-embracing 2c, but why do we have to wangle things? Our patients try to understand our difficulties, but they often make it worse. In my most oft-recurring nightmare I see myself surrounded by yellow cards with shadowy voices. There is the stiff upright card: "I don't want treatment, but I need my milk." There is the drooping bent card: "The milkman says he's got plenty; all he wants is a certificate." There is the crumpled and shabby old card: "I've had a glass of milk for supper all through the war; the other doctor gave it to me; I can't sleep without it." They draw near. They point accusing corners at me. In my dream I even see the often offered shilling. Mercifully the phone rings and the dream is gone, but the question remains. We were never taught about milk certificates at our medical schools. No examiner questioned us on this knotty point. We are simple people. We try to be fair to all and we please none. We are the scapegoats of the Ministry of Food and we don't like it.

* * *

Having bought a really new house I was determined not to lose it to the anarchists. (I feel sorry for them, but I am determined to assert myself too!) The house had recently been left empty, and pending the move from the present one into the new one I suggested that my wife should put up some curtains. "Curtains!" she scoffed. "They wouldn't keep me out if I were a squatter." While I was distempering the empty rooms between visits the idea arrived—I would get all our friends who could spare the time during the local rush hour to come in and look round and spend as long as they could offering suggestions.

One evening this was in full swing, with cars parked all over the place and a fearful hullabaloo going on, those in the garden calling to those in the bedrooms, when a young man walked in through the gate and produced a notebook. "This is it," I murmured to myself. He came towards me, as I was the tallest in sight, and asked, "Are the squatters in?" adding, "I'm from the *Bull Valley Tribune*, the local rag, y' know."

"Young man," I said, looking as unbalanced as I could, "are you in need of a home, a haven from the tortures and affliction of the world, where the upward-licking flames from the fiery furnace below cannot reach . . .?" He seemed to take in the situation in one terrified glance. "No," he said; "not at all, thank you sir," and he left hurriedly, without shutting the gate.

Two days later the professional plate which I had ordered months ago arrived, so I hurried down to the new house and put it up. Patients and friends alike (they have long ago forgiven me) agree that the plate has finally decided the issue between anarchy and order. "After all," they say, "when you have your name on it. . . ." Which is saying something, even in these days.

* * *

There ought to be a course of instruction in testimonial writing. Just now many of us are enjoying the exceedingly difficult experience of sitting in judgment on youthful aspirants to honorary staff appointments. So erudite, so distinguished do they all appear that they inspire in us a sense of shame at being accepted as competent arbiters and a sense of self-congratulation that in our day competition was less acute. What tests should we employ in a decision so momentous? How can we prepare ourselves to hold the scales in fairness to the claims of the applicant and to the interests of the hospital and, it may be, of the medical school?

I don't know. Errors in judgment are notorious. I ecall a man who was selected on the most enthusiastic ecommendation of a president of the R.C.P., a president whose integrity and wisdom were universally accepted and revered. For thirty years this paragon blocked the path of anxious, embittered juniors, and during that thirty years he was a useless encumbrance who taught nobody anything and made not the smallest contribution to medicine. Alternatively every school exhibits its inability to recognise exceptional potentiality and to deplore the loss which has proved a rival school's gain.

To assist us in our deliberations we have—testimonials. In many instances these comprehend no more than a bare recital of the applicant's appointments and other details of his career which we could learn for ourselves by consulting the *Medical Directory*. The majority of others consist of platitudinous assurances that "he is a sound physician," "has an extensive knowledge of medicine," "is hard-working and conscientious," "I think he would prove a very agreeable colleague," "he has read extensively," "is of stirling character" (yes, the misspelling has appeared on not a few occasions).

Of more value—indeed it ought to be of very great value—is the personal letter. Now this calls for considerable care in its composition unless it leads the recipient to read between the lines and conclude that it emanates as a formal response to a request rather than from a genuine desire to do all possible for the applicant. Look at these:

> "A. B., who was my house-physician, is applying for the vacancy of assistant physician at your hospital. Unless you have somebody outstanding, you might do worse than select him."
>
> "I have not worked with A. B. personally but I am told he is a very good physician."
>
> "Although I can only speak from second-hand experience, I should say his work in the war was well above average."
>
> "As far as I could judge, he was entirely trustworthy."
>
> "He is an excellent teacher of the *list* type." (I suppose this interpreted means—you have been warned !)

Being damned with faint praise is bad enough, but there is a far graver danger to the seeker after testimonials. In my early days I encountered a sequence of failures until a real friend dropped a pretty broad hint that I would never be selected anywhere so long as I presented a testimonial from Dr. X. In my innocence I had congratulated myself on being sponsored by this prosperous and celebrated physician. How was I to know that this man whom I had thought to be famous and distinguished had a reputation among his colleagues which led them to substitute the adjectives infamous and notorious, a man whom the ladies called a duck and other doctors labelled quack ? Presumably the converse holds good, although I find it difficult to visualise anyone with the confidence to utilise a testimonial of the opposite kind because it was written by one "of whom," in the words of Milton, "to be dispraised were no small praise."

* * *

Having just returned from a 1500-mile tour through Germany, I am happy to be able to announce the cause and cure of the "German problem." From time to time the Germans hear rumours that other nations possess beds in which it is possible to sleep, and, since conquest is the only means of acquisition known to the German mentality, they immediately start a war of aggression. The cure is therefore obvious. Compel the Germans to manufacture and make up their beds according to civilised specifications and they will remain in them tranquilly ever after. When I think of the tripartite boards that pose as mattresses, the absence of pillows, the untucked sheets, the . . . but far abler pens than mine have spent themselves in vain on that supreme example of Teutonic masochism.

* * *

Talking of the discretion of the British press, a woman starting a play group in London approached the advertisement manager of a national paper and unfortunately mentioned that the group was to be run on psychological lines. His response was immediate and final. "Psychology; no, we cannot touch this. We bar advertisements dealing with psychology, astrology, racing tips, and rubber goods."

Letters to the Editor

PSYCHONEUROSIS TREATED WITH ELECTRICAL CONVULSIONS

SIR,—Dr. Milligan's interesting paper raises many issues, but it is particularly towards the presentation of the material that criticism may be directed.

New treatments are judged by the careful selection of material, accurate diagnosis, criteria of recovery, adequate follow-up, and finally by acceptable presentation. In this paper all these points are open to criticism.

1. No criteria are given for the selection of cases, nor is there evidence of adequate examination preceding treatment.
2. The published case-histories leave room for doubt as to the correctness of the diagnosis ; for example, case 7 could well be an involutional melancholia.
3. "Recovery" apparently depends on "stability," but we are given no hint of the method adopted in forming this judgment.
4. Only case 5 has an adequate follow-up. It is a pity that some of the cases followed for 5 years have not been included.

These points are a sufficient criticism of the presentation of results ; but further information is required for general recognition of this new method of treatment. Scant consideration is given to the possibility that these patients have been "electrically leucotomised." Hypochondriacal features are most noteworthy in the histories ; and the work of Freeman and others has indicated the effects of leucotomy on the chronic complaint habit. The question of deterioration is also most briefly considered ; we are given a dogmatic denial of Brodie's findings, but no supporting evidence ; and the absence of gross memory disturbance does not rule out deterioration, as Professor Golla has shown in leucotomy cases.

With the memory of other enthusiastic first reports on physical methods of treatment in psychiatry and their subsequent fate, I cannot feel that we are yet justified in recommending our neurotic patients to enter mental hospitals for this treatment. Even with electrical convulsions to "Music While You Work," the lay public will, I fear, continue to regard the mental hospital as a madhouse.

London, W.1. P. H. TOOLEY.

SIR,—Dr. Milligan's article is courageous and impressive. But, despite the recovery-rate, it contains features that give rise to concern.

He advocates this method for selected cases, but offers no criteria for selection, apart from chronicity—the duration apparently ranging from 2 to 20 years. Nor are the "general lines" of treatment in case 6 clear ; surely the treatment prior to convulsive therapy might have been described.

Plausible as is the explanation by Brain and Strauss, is it a sound basis for giving up to four major convulsions daily, or for producing a condition in which the patient is reduced to the infantile level, with double incontinence ? What proof is there that gross damage has not been done by the repeated severe neuronal disruption ? Even if sequelæ are not immediately evident, they may still be forthcoming.

Dr. Milligan is indeed fortunate not to have seen protracted memory defects in these cases. I have under observation a woman of 25 with an anxiety state, who had previously been given 18 major convulsions in 6 weeks, and who now has a profound memory-defect for recent and remote events—a defect that impairs intellectual work. Though convulsive therapy may have a place in the treatment of psychoneuroses, its adoption as recorded by Dr. Milligan cannot be accepted with unreserved enthusiasm.

Todmorden. NORTHAGE J. DE V. MATHER.

SIR,—Of his 100 cases of psychoneurosis treated intensively by electrical convulsions Dr. Milligan classifies 52 as recovered on discharge, and he claims that a further 45 or 46 were much improved, most of them symptom-free. These results might appear to compare favourably with those of psychotherapy carried out under hospital conditions, while the amount of the physician's time occupied in the administration of treatment seems to have totalled rather less than five minutes apiece in the

LONDON'S VOLUNTARY HOSPITALS

THE continued practical interest of the public in the voluntary hospitals of London during 1945 is well demonstrated in the Annual Statistical Summary for that year just published by the King's Fund.[1] Despite a decrease of £67,000 in the income from public authorities, the total maintenance income of the 164 hospitals reached a record figure of £6,879,000; in addition £156,000 was given for endowment and £439,000 for building and equipment, making a grand total of £7,474,000, or £523,000 more than in 1944.

Income from subscriptions and donations rose by £135,000 to £1,276,000; patients' contributions by £227,000 to £1,120,000; and contributory schemes by £175,000 to £912,000. Legacies, a source of income which many predicted would suffer as the result of death duties, high taxation, and other adverse economic conditions, rose by £121,000 to £676,000. If "free legacies" are included, no less than 74·5% of the total maintenance income came from sources other than public authorities. Maintenance expenditure amounted to £6,466,000, or £625,000 more than in 1944, leaving a surplus for 1945 of £413,000.

The number of new inpatients rose from 206,000 to 236,000, and the average number of beds occupied daily from 10,447 to 12,797. The number of new outpatients was 1,641,000 and the number of outpatient attendances 7,888,000.

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED OCT. 12

Notifications.—Smallpox, 0; scarlet fever, 1106; whooping-cough, 1362; diphtheria, 269; paratyphoid, 6; typhoid, 3; measles (excluding rubella), 2005; pneumonia (primary or influenzal), 351; cerebrospinal fever, 37; poliomyelitis, 22; polio-encephalitis, 1; encephalitis lethargica, 1; dysentery, 44; puerperal pyrexia, 156; ophthalmia neonatorum, 69. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on Oct. 9 was 835. During the previous week the following cases were admitted: scarlet fever, 59; diphtheria, 22; measles, 13; whooping-cough, 35.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (1) from enteric fever, 1 (1) from measles, 12 (0) from whooping-cough, 5 (0) from diphtheria, 44 (2) from diarrhœa and enteritis under two years, and 9 (3) from influenza. The figures in parentheses are those for London itself.

There were 4 fatal cases of whooping-cough at Manchester. Liverpool and Manchester each reported 6 deaths from diarrhœa and enteritis.

The number of stillbirths notified during the week was 258 (corresponding to a rate of 26 per thousand total births), including 35 in London.

MIDWIVES' PAY

EMPLOYING authorities have been advised by the Ministry of Health to adopt new recommendations by the Midwives Salaries Committee. These include a special service allowance of £20 at the end of each year's full-time employment for all (other than pupil) midwives. It is hoped that this grant may encourage more women who have the necessary qualifications to practise. The committee has now completed its review of all salaries. Under the revised scale a matron of a maternity hospital with 100–199 beds will receive a salary (inclusive of emoluments) ranging from £550 to £750, compared with the old range of £450 to £650; and a new inclusive salary ranging from £600 to £825 is recommended for matrons of institutions with 200 or more beds. Corresponding increases are recommended for matrons of the smaller hospitals and homes; and assistant matrons in institutions with 50 or more beds will now receive £410 to £485. Resident district midwives will now have a salary of £290 to £380, compared with the former £240 to £300. The committee has also recommended that part-time midwives should be given credit for years of previous service; and employing authorities are given discretion to increase the appropriate salaries by 10%.

In England Now

A Running Commentary by Peripatetic Correspondents

THE fact that hard-working G.P.s are given the task of allocating the nation's milk is certainly not an inducement to take up medicine. True, we are given a list of deserving cases entitled to extra milk, and on the face of it our task is easy. A pregnant woman gets her 1½ or 2 pints daily; so do sufferers from G.U. or T.B. This we can understand, but here comes the rub. Why does a man with a broken arm, being "an active worker on the panel," get his daily pint while our edentulous old dears in the 80's get nothing extra? Questions like this are unanswerable. Of course, we may stretch a point and give an occasional pint under the all-embracing 2s, but why do we have to wangle things? Our patients try to understand our difficulties, but they often make it worse. In my most oft-recurring nightmare I see myself surrounded by yellow cards with shadowy voices. There is the stiff upright card: "I don't want treatment, but I need my milk." There is the drooping bent card: "The milkman says he's got plenty; all he wants is a certificate." There is the crumpled and shabby old card: "I've had a glass of milk for supper all through the war; the other doctor gave it to me; I can't sleep without it." They draw near. They point accusing corners at me. In my dream I even see the often offered shilling. Mercifully the phone rings and the dream is gone, but the question remains. We were never taught about milk certificates at our medical schools. No examiner questioned us on this knotty point. We are simple people. We try to be fair to all and we please none. We are the scapegoats of the Ministry of Food and we don't like it.

* * *

Having bought a really new house I was determined not to lose it to the anarchists. (I feel sorry for them, but I am determined to assert myself too!) The house had recently been left empty, and pending the move from the present one into the new one I suggested that my wife should put up some curtains. "Curtains!" she scoffed. "They wouldn't keep me out if I were a squatter." While I was distempering the empty rooms between visits the idea arrived—I would get all our friends who could spare the time during the local rush hour to come in and look round and spend as long as they could offering suggestions.

One evening this was in full swing, with cars parked all over the place and a fearful hullabaloo going on, those in the garden calling to those in the bedrooms, when a young man walked in through the gate and produced a notebook. "This is it," I murmured to myself. He came towards me, as I was the tallest in sight, and asked, "Are the squatters in?" adding, "I'm from the *Bull Valley Tribune*, the local rag, y' know."

"Young man," I said, looking as unbalanced as I could, "are you in need of a home, a haven from the tortures and affliction of the world, where the upward-licking flames from the fiery furnace below cannot reach . . .?" He seemed to take in the situation in one terrified glance. "No," he said; "not at all, thank you sir," and he left hurriedly, without shutting the gate.

Two days later the professional plate which I had ordered months ago arrived, so I hurried down to the new house and put it up. Patients and friends alike (they have long ago forgiven me) agree that the plate has finally decided the issue between anarchy and order. "After all," they say, "when you have your name on it. . . ." Which is saying something, even in these days.

* * *

There ought to be a course of instruction in testimonial writing. Just now many of us are enjoying the exceedingly difficult experience of sitting in judgment on youthful aspirants to honorary staff appointments. So erudite, so distinguished do they all appear that they inspire in us a sense of shame at being accepted as competent arbiters and a sense of self-congratulation that in our day competition was less acute. What tests should we employ in a decision so momentous? How can we prepare ourselves to hold the scales in fairness to the claims of the applicant and to the interests of the hospital and, it may be, of the medical school?

and woman—for instance, work, food, housing, and clothes. It was not that these were provided, but that the individual need not worry about their provision, which enhanced the sense of security.

With the end of the war, morale inevitably worsened. The sudden disappearance of the overriding communal motive, together with the natural relaxation after a period of tension, would have sufficed to make a disruptive social picture even without the loss of the sense of security resulting from material shortages, the return of forgotten husbands to homes "otherwise occupied," the unconscious guilt of those who left their families, and the less unconscious (even if still unjustified) guilt of those who stayed at home.

To restore morale we have to restore both the sense of purpose and the sense of security. It might be possible to maintain morale, as the Russians seemed to be doing, by inventing new fears of war which would bind the people together against a common, even if so far a hypothetical, enemy; but to do this would require a further denial of democratic government which our people would fortunately not tolerate. It would in any event only delay the realisation of the individual's, as opposed to the State's, insecurity.

To return to the problem of health. The sense of security is to a much larger extent than is generally realised dependent on interpersonal contact between members of a community, and to a much smaller extent on the physical conditions of security. We may therefore aim at increasing social contact between people. There is ready to hand an adequate motive for health-giving activity in a war-weary country: *recreation.* A blueprint for action along these lines is, I think, to be found in the accounts of that admirable social experiment, the Pioneer Health Centre at Peckham. By laying emphasis on recreation, a motive is provided which is universally acceptable and which is persistent. By providing a focus for interpersonal exchange and communal integration, and by having the centre run under the guidance of properly trained biologists, every opportunity is given for the development of the sense of security. Morale is improved and a rich soil prepared for the seeds of health education.

Dr. Kennedy speaks of the need for more recreational facilities and for more biologists. It is important to emphasise that these two must be closely linked. Biology is the science of life; and inasmuch as "recreation" is a subject for science, it is the biologist's responsibility. In conclusion, we may remind ourselves that medical education—at least up to 1939—used a fragmentary rather than a holistic approach; and that our profession is primarily oriented toward the relief of illness, secondarily toward the maintenance of health, and only thirdly toward the enhancement of positive health. In the nature of medical work, as at present taught and organised, we see more and think more about disease than about health. A great deal of hard thinking and versatility will be required by our profession if we are to make a real contribution to this problem.

Narborough, Leicestershire. JAMES R. MATHERS.

PILONIDAL SINUS

SIR,—Mr. Patey and Professor Scarff (Oct. 5, p. 484) make two questionable assertions.

(1) They say there is a world of difference between sacrococcygeal cysts and tumours of undoubted developmental origin and pilonidal sinus. They claim that the pilonidal sinus is higher in the natal cleft, but those of us whose lot it is to see a disproportionate number of children's posteriors have seen many more than the 16 cysts and tumours of developmental origin which Raven collected in London museums. It is true that some of these are very near the anus but most are high up and all grades are seen from the massive dermoid to the short sinus and dimple.

(2) They stress the importance of hair in the ætiology. Surely this very fact emphasises the developmental origin of the pilonidal sinus. The body hair does not grow until stimulated by puberty hormone levels, and it is the young adult in whom the symptoms first develop most commonly. It is difficult to believe that the tough tissues of the sacrococcygeal region can be pierced by a human hair which has been sat on.

One of the reasons for so many failures in treatment during the war has been that the advent of powerful chemical bacteriostats has tempted the surgeon to "try his luck" and close primarily the gaping chasm of his wise and wide excision. Healing *of* the bottom *from* the bottom must still remain a fundamental rite.

London. D. F. ELLISON NASH.

TUBERCULOSIS FOLLOWING INJECTION

SIR,—Several interesting points emerge from Mr. Ebrill and Dr. Elek's account of a tuberculous abscess arising at the site of a previous intramuscular injection of penicillin (Sept. 14, p. 379). Although the authors do not use the term, it is clear that they regard the abscess as an example of *primary* tuberculosis (i.e., arising in a previously uninfected individual, who would have been tuberculin-negative had he been tested before the penicillin injection). One cannot, of course, be dogmatic, but the clinical details given are far more suggestive of a *post-primary* tuberculous abscess (i.e., arising in a previously infected allergic individual, whose Mantoux reaction would have been positive previously had it been tested). Such a post-primary abscess *could*, of course, have arisen as a result of introducing virulent tubercle bacilli during the penicillin injection, but this is extremely unlikely. Bacilli accidentally inoculated into tuberculo-allergic individuals in this way are usually effectively dealt with by the body's defence mechanism, as was first shown many years ago by Koch when he described what is now known as the Koch phenomenon. The most likely explanation is, I think, the one which Ebrill and Elek dismiss as a practical impossibility—namely, that the abscess arose as a blood-borne infection. Such disseminated tuberculous abscesses are by no means rare in sanatorium practice, particularly in the so-called hæmatogenous type of disease, and in the case described the hæmatoma appears to have acted as a *locus minoris resistantiæ.* The fact that clinical and radiological examination has revealed no other tuberculous focus is, of course, inconclusive; it is quite common not to find a primary tuberculous focus in persons undergoing Mantoux-conversion while under observation (e.g., in sanatorium staff). In such cases the site of infection may be in the alimentary tract.

Two clinical details would have been helpful. Firstly, no mention is made of the presence or absence of inguinal adenitis. With a large primary tuberculous abscess of the thigh, caseous adenitis of the regional lymph-nodes would almost certainly have occurred, while "drainage" glands of a post-primary abscess, if examined by biopsy, could have been distinguished histologically by the relative absence of caseation. Secondly, no mention is made of the type of bacillus recovered from the pus. The finding of bovine bacilli would have been a pointer, admittedly a weak one, to the presence of a bovine alimentary infection.

It might be of interest to note that by a curious coincidence two patients and a possible third have been admitted to this hospital during the last month, each with lupus verrucosus of the hand following an injury involving a breach of skin surface. It is tempting to picture the very natural reaction of sucking the injured member (and both patients have active pulmonary lesions), but it is far more probable that these are also examples of a hæmic infection of a *locus minoris resistantiæ.* The well-known association of injury with other tuberculous conditions, such as tuberculosis of joints, is also very much to the point.

Dr. Marsh's statement (Oct. 5, p. 508) that "tubercle bacilli are not uncommon in the dust of hospital wards" cannot be allowed to pass unchallenged, since it tends to perpetuate the erroneous belief that sanatoria and tuberculosis wards are dangerous places in which to work because of the risks of infection from dust. Since Cornet, in 1889, claimed to have found tubercle bacilli in 40 out of 140 specimens of dust from various German hospitals, public buildings, and tuberculosis wards,[1] belief in the rôle of dust as one of the chief infective agents in tuberculosis has been widely held, although few modern tuberculosis pathologists now subscribe to

[1] Cornet, G. *Z. Hyg. InfektKr.* 1889, 5, 191.

7 cases quoted, as against the many hours required for psychotherapy. Even the doubtful acceptance of such results might encourage those who are planning our National Health Service to fob off the unfortunate sufferer from psychoneurosis with some more or less harmful form of physical treatment, under the pretext that it is the most modern and effective known to medical science.

I suspect that Dr. Beaton's treatment is in all essentials a regression to the therapy of the last century, fortified by modern apparatus.

Some 37 years ago, as a young man in general practice, I was called out very urgently to a woman said to be on the point of death. In a poor house in a mean street I found, in the centre of an excited crowd of neighbours, a married woman of about 35 lying apparently unconscious, but performing forced respiration with amazing energy. I could find no signs of physical disease, but my questions elicited no response of any kind from the patient. Being satisfied that I had to deal with an exhibition of hysteria, I turned everyone out of the room and sat down quietly with notebook and pen to observe the patient, whose breathing still continued violent and rapid. She probably noticed the sudden change from confused noise to complete silence, and after a minute or two opened her eyes and looked at me. I said: "Don't you think you might *as well stop that performance? It must be very tiring.*" Her respiration became normal immediately, and she began to cry. After about five minutes of this I asked her whether she felt better; she said she did. I pointed out severely that she had caused much unnecessary alarm to her friends by her behaviour, and left after obtaining her promise not to do it again. I was quite pleased with my successful treatment, and so were the relatives and friends. Only the patient seemed to have no sense of relief or satisfaction, and I remember being struck by her attitude of quiet despair in contrast with her former excitement; but I was not interested in the case except as providing an opportunity for showing my skill in handling an hysterical outburst. I did not see her again, but I think I should have been called by the relatives if there had been any return of her symptom; the case was probably cured, by Dr. Milligan's standards.

Ten years later, having begun to learn something of the causes and treatment of this kind of illness, it occurred to me that if my understanding had been greater I should perhaps have encouraged this patient to tell me what was really troubling her, with the probable result that her display of emotion would have lasted very much longer while her relatives might have been called upon to improve their relationship with her. No doubt everyone except the patient would have regarded me as a very incompetent doctor; yet I might have performed a service of the greatest importance to the patient. As it was I had only intimidated her from further self-expression by a metaphorical bucket of cold water.

Is intensive electro-convulsive treatment really an advance upon the bucket of cold water which used to be the treatment for hysterical manifestations most favoured by bold therapists in the nineteenth century? In selected cases—and Dr. Milligan's cases were carefully selected—it commonly resulted in the complete disappearance of symptoms (sometimes, one gathers, for good), and results might have been still better if it had been applied intensively and unemotionally.

I do not deny that intensive convulsive therapy may be expected to produce more permanent results. It seems likely from Dr. Milligan's account that it is followed regularly by the commencement of a process of mental deterioration, and it may be that this, like leucotomy, damages the symptom-producing structures; but if this is so, such treatment should be reserved for the most desperate cases, after careful consideration by a responsible medical board.

Other questions present themselves. Does the theory, adopted by Dr. Milligan, that Dr. Beaton's method obliterates entirely the faulty electrical patterns of the brain mean that electro-encephalograms recorded before and after treatment showed the disappearance of *abnormal rhythms?* If not, does it mean anything? On what basis were these 100 cases selected for publication from the larger number of psychoneurotic patients treated by intensive electro-convulsive therapy? And does an average dose of "180 volts at 0·4 sec." mean anything but a large unmeasured dose?

These questions are minor matters, and it may well be that the intensive method described will prove valuable for the treatment of some severe cases which might otherwise be properly subjected to leucotomy. The large issue is between the view that the patient should be treated in the way that is best for him individually, and the opposed view that treatment should be adapted to the convenience of those who have to apply it and those who have to pay for it. I would suggest that the patient and his human environment should both receive full consideration. Each should be represented on a board which would consider on its merits every case in which it might be proposed to take action destructive of the integrity of human life; such actions would include the termination of pregnancy for reasons other than the preservation of the life of the mother, prefrontal leucotomy, and intensive convulsive treatment.

If the treatment described by Dr. Milligan is considered justifiable in the case of ordinary psychoneurotic patients, it seems to follow that it should be used also on habitual criminals, and then on the masses of ex-Nazis whose re-education is a yet unsolved problem. If Dr. Milligan is right, the "obliteration of psychologically unacceptable patterns of thought and conduct" can be effected in a few days, and then someone can carry out the *resynthesis* of their personalities along correct lines. One is glad Dr. Milligan sees that this is a task requiring much care and judgment.

London, W. J. NORMAN GLAISTER.

MORALE OF THE NATION

SIR,—I was glad to see that Dr. Kennedy, in the lecture on Health Education published in your issue of Sept. 21, emphasises the principle of holism in the doctrine of positive health. I was less glad to see that, while he notes the importance of "moral discipline," he is apparently prepared to leave this fundamental aspect of the matter to the individual conscience. In so far as moral discipline affects health, we should make an effort to provide some biological guidance for it.

I suggest that we use the term "morale" instead of moral discipline. Even if no more clearly defined, its various definitions are less likely to be coloured by the emotional prejudices of different sects. Without discussing the definition of the concept of morale (which would only recapitulate what Dr. Kennedy says of the definition of health), one can, for purposes of discussion, divide the factors which influence it into components which foster (*a*) a *sense of security*, and (*b*) a *sense of purpose*. The sense of security is essentially the feeling of "belonging" to a group, and has no implications about the actual physical conditions which might be held to make for security. Its antithesis is the sense of isolation, or "separation anxiety." The sense of purpose is essentially the feeling of "worthwhileness," and can exist apart from any explicitly stated aim or intention.

These two concepts are both aspects of a state of mind which is of course largely unconscious and little subject to deliberate control. Their formulation as separate entities allows us to estimate the value of any particular measure as an aid to morale. The sense of security relates to the individual's potential, while the sense of purpose relates to the direction in which the potential will be used. Needless to say, a particular morale factor will have effects on both aspects: thus a good leader will both provide an adequate motive for action and enhance his followers' sense of security, while the provision of excessive "welfare" facilities may enhance the feeling of security but confuse the sense of purpose.

In war-time, morale was tackled from both angles. The sense of purpose was fostered by repeated (and not always effective) efforts to render war aims explicit; and on a lower but more effective plane by the setting up of "targets"—for production, war savings, &c. The feeling of security was fostered in many ways, by no means all of them deliberate: "One spot of bombing makes the whole town kin," and people came into close contact with their neighbours in a way almost unattainable in peace-time. The necessities of the time caused the State to assume a paternal rôle which relieved many of the day-to-day anxieties of life for the ordinary man

Parliament

THE LORDS IN COMMITTEE

ON Oct. 17 the House of Lords resolved into committee under the chairmanship of the Earl of **DROGHEDA** to consider the National Health Service Bill.

POWERS OF THE CENTRAL COUNCIL

Lord **MORAN** moved an amendment to clause 2 with the purpose of strengthening the Central Health Services Council. The Bill was singularly free from the fault of trying to meet sectional interests at the expense of the community, but he thought it unfortunate that membership of the council had been allowed to grow to 41. This inevitably meant that there must be a number of advisory committees, which were to be appointed by the Minister and to report direct to him, though they would at the same time report to the council. The amendment mpowered the council to appoint these committees nd laid down that they should report to the Minister hrough the council. He thought this vital, for a Minister aced with a council of 41 and an alternative committee f 8 or 9 experts would naturally turn to the experts. hus the committees would do the real work and the ouncil would be largely robbed of its chief function. id this matter? He thought it did, for at present those ctively engaged in the practice of their profession layed little part in administering the service, and it was oped that the council would be a means whereby they ould take an active part, not only once or twice a year ut in every important thing that came before the Minister concerning health. Lord **JOWITT**, the Lord hancellor, in reply, pointed out that the Minister before ppointing a standing committee must consult with the entral Health Services Council. He agreed that it was mportant that the council should be really effective; ut it was rather an unwieldy body, and for that reason nd not because they wanted to belittle the authority f the council the Government felt unable to accept he amendment—which was by leave withdrawn.

ACCESS TO HOSPITALS

The Earl of **MUNSTER** moved an amendment to clause 4 o ensure that voluntary hospitals should not *find after* he passing of the Bill, on instructions from the Minister, that their small rooms must be abandoned and made into large wards. Lord **JOWITT** gave an assurance that these rooms would not be converted unless it was found really necessary in the interest of the whole service, and the amendment was withdrawn.

Lord **LLEWELLIN** moved an amendment to clause 5 allowing a doctor to follow his patient into a hospital even though he was not a specialist on the staff of that hospital. Lord **HORDER** supported the amendment, for he declared it was in the interests of the patient that continuity of treatment should be preserved.

The Earl of **LISTOWEL** pointed out that the effect of the amendment would be that a specialist or practitioner who chose to stay outside the public service would be able to use for his private work hospitals provided at the public expense. Viscount **CRANBORNE** suggested that as the patient had made his contribution to the scheme presumably he had the right to enter a State hospital. The clause as it stood allowed *any doctor on* the staff of a hospital to treat his private patients in that hospital, but the man outside the service could not even arrange for his patients to be treated by someone else at the State hospitals. He was in favour of a State service, but he did not believe that there should be this continual whittling down of private practice so that in effect it was really useless. Lord **ADDISON** pointed out that today medical practitioners who sent their patients into hospital did not follow them. The patients were treated by members of the hospital staff. The amendment was withdrawn.

The Earl of **IDDESLEIGH** moved an amendment incorporating the pledge which the Minister had given that the character of denominational hospitals would be respected, but withdrew it on Lord **JOWITT** promising to consider the matter before the report

HOSPITAL ENDOWMENTS

Viscount **MAUGHAM** moved an amendment extending to the non-teaching hospital the proviso safeguarding the confiscated endowments of the teaching hospitals

> "Provided that the Board shall, so far as practicable, secure that the objects of any such endowment are not prejudiced by the provisions of this section."

In reply Lord **JOWITT** said there was no doubt that by Act of Parliament any trust could be disturbed. Whether it should be was another matter, and he agreed that it should not be done lightly. There was, he pointed out, a profound difference with regard to the endowments of the teaching and non-teaching hospitals. In the teaching hospitals no redistribution was contemplated. The existing funds remained with the hospital, though the board of governors was changed. But *redistribution* was the very essence of the scheme for the voluntary hospitals. The scheme would probably cost the public Exchequer something like *£150 million* a year. Approximately £30 million would come from the insurance contributions, some £10 million from local authorities, and the remaining £110 million from the Exchequer. Of the whole £150 million some £90 million would be expended on hospitals. The reaction of the Treasury officials to this enormous expenditure had been: "If you are going to call on us to find out of public funds this vast sum of money, at least you ought to let us have in return the various endowments to put against our obligations." The Chancellor of the Exchequer had been persuaded to forgo that claim, for the Government was anxious that the hospitals should have some cushion between themselves and the rigours of Treasury control. But it seemed only fair that this *nest-egg* should be redistributed so that all should have a share. The probable capital value of the endowments was something like £50 million which at 3% would give something like £1$^1/_2$ million a year, and even that figure probably contained a not inconsiderable element of the endowments of teaching hospitals. The effect of the amendment would be to smash up the scheme, for there was hardly an endowment which had not been given to some specific hospital. If the scheme became impossible, inevitably the Treasury would say to a hospital which was richly endowed, "You are so well off that you need not have a large amount of public funds," and the whole idea of this cushion would go.

Viscount **SAMUEL** suggested that a comforts fund would really fulfil the purpose of the ancient donors of these endowments, for their only desire was that the sick should be well cared for and happy, and they would not mind very much whether the hospital had the name of Saint So-and-so or was called the Manchester Central Hospital. Therefore it seemed to him that we were fully entitled to endorse a change of trusts which arose out of the different circumstances of our own times. But could not some words be inserted which would ensure that what was done was done without detriment to the general purposes of the endowment and with the intention to fulfil as far as possible the wishes of the donor? For example if it were merely a question of a hospital being named for all time "The 1914–18 War Memorial Hospital" obviously that sort of trust ought to be fulfilled. Lord **JOWITT** replied that he fully accepted Viscount Samuel's example, and that where a gift was *attached to a condition*—such as the upkeep of a garden—he was ready to consider an amendment provided it was limited to such special cases, and did not seek to say that any money merely because it was left to a particular hospital should therefore be exempted from pooling and redistribution.

REGIONAL BOARDS

Lord **ADDINGTON** and Viscount **BRIDGEMAN** moved amendments to ensure that the local health authorities should know what plans the regional boards were making and should have a chance of putting their views to the Minister before any regional plan was finally accepted. The Earl of **LISTOWEL** pointed out that the Minister must include members of local authorities among the people he appointed to the regional boards, and they would no doubt keep their colleagues informed of what was happening. Viscount **SIMON** suggested that the language of the Bill regarding these appointments might this view (e.g., Gloyne[2]; a good summary of the *dust* v. *droplet* controversy is given by Topley and Wilson,[3] who point out that the English climate militates very strongly against the formation of dust containing living virulent tubercle bacilli). Even if one accepts Cornet's work without question, few will deny that personal hygiene is now vastly improved since his day, largely as a result of public-health propaganda; our tuberculous patients no longer spit on the ward floor! Numerous investigators have failed to find living tubercle bacilli in the dust of modern hospitals and sanatoria.

An investigation was recently made at this hospital into the possible infectivity of occupational-therapy articles made by patients. One hundred articles of all types (plastic, wood, wool, felt, &c.) made by patients with all degrees of lung involvement (many producing large amounts of positive sputum daily) were examined carefully in the hospital laboratory, where the technique of cultural examination for tubercle bacilli has been brought to a high standard; not one positive result was obtained. I am sure that this is in large measure due to the careful instruction in the hygiene of cough which is given to all patients. The danger of infection from patients with open pulmonary tuberculosis is not from ward dust but from unrestrained cough. It is clear that this fact needs to be emphasised at a time when hospital and sanatorium domestics are at a premium.

A. G. HOUNSLOW.

County Sanatorium, Clare Hall, South Mimms, Barnet.

FOLIC ACID IN CŒLIAC DISEASE

SIR,—The course of cœliac disease in children is often so protracted, and the prognosis so uncertain, that we venture to draw attention to its treatment with folic acid, a procedure which in a particular case has so far proved dramatically successful.

A boy, aged 17 months, came under the care of one of us (L. G.) in May, 1946. There was a history of vomiting and diarrhœa with the passage of numerous pale bulky and foul-smelling stools during the previous 6 months. He had been under treatment by another doctor during this period, with no improvement.

He presented the typical appearance of cœliac disease —pale, apathetic, with a dry skin and distended abdomen and wasted buttocks, and with the stools as described above. His weight was 19 lb. Treatment with parenteral liver extract 2 c.cm. on alternate days, together with ascorbic acid and 'Benerva' Compound tablets by mouth and a fat-free diet was instituted. Improvement was rapid. The vomiting and diarrhœa ceased and he gained weight.

The child was taken away on holiday, but after a month he relapsed and became extremely ill with a return of his former symptoms. He was admitted to hospital weighing 21 lb., but after a fortnight's stay his condition had deteriorated considerably and he was taken home weighing only 14½ lb. He was then seen in consultation by one of us (H. P. B.) and admitted to hospital in a serious condition. The picture was typical of cœliac disease. He was grossly dehydrated and passing 15–16 stools a day. He could take only very small quantities of skimmed milk with water and glucose. The blood-count showed a secondary anæmia with 52% hæmoglobin and 4,200,000 red cells per c.mm. The total fat in the stools was 49%.

Treatment with parenteral liver extract and vitamin-B complex on alternate days, together with other vitamin supplements and iron by mouth, was begun, and during the next week there was no improvement although no deterioration in his condition and his weight remained stationary.

At this stage a supply of folic acid was obtained and 25 mg. per day was administered by mouth. There was *immediate* improvement. The following day only 2 stools were passed, the appetite returned, and he became much calmer and brighter. From then on he progressed rapidly. His appetite became ravenous and he took a good mixed diet, fat-modified, and passed one or two pale formed and non-offensive stools each day. At the end of a week he had gained 7 lb., and 9 days later he had gained a further 6 lb. At the moment improvement has been maintained but there is still considerable abdominal distension. The dosage of folic acid has been reduced gradually and he is now taking 10 mg. per day. All other treatment has been stopped since the institution of the folic acid.

It is impossible, of course, to draw any general con- clusions from a single case, but we feel strongly that improvement in this case can be attributed solely to folic acid.

No doubt intensive trials in this direction are going on, but we have so far seen no recorded work on the treatment of cœliac disease in children with folic acid.

H. P. BRODY.
Sheffield. L. GORE.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—I am anxious to correct two impressions that Mr. Deitch's provocative and stimulating letter of Oct. 19 may give.

He mentions that for two years I have treated all cases of acute perforation conservatively and "with uniform success." This series was reported at a meeting of the Leeds Medico-Chirurgical Society in February, 1946. I did not invent the conservative method any more *than Hermon Taylor did.* Many surgeons *practise* conservative treatment in selected cases, and it was not until Bedford Turner reported 6 cases (*Brit. med. J.* 1935, i, 457) that I had the courage to treat all cases without selection. Further, I have lost 3 cases since the discussion in February, which makes the mortality 18% in my small series. I agree with your leader of Oct. 5 that since we have no means of determining which ulcer will close spontaneously, conservative treatment will inevitably cause the surgeon more anxiety than simple closure, which, in Mr. Deitch's hands, carries a mortality of only 4%. This remarkable record, extending over eight years, fully justifies his belief in spinal anæsthesia and no drainage-tube.

Our experience in York differs from Hermon Taylor in two respects. We found considerable constitution disturbance in several cases, the pulse-rate rising t 130 per min. and the temperature to 103° F, fallin gradually to normal by the eighth day, and we had patients who developed subphrenic abscess, a complic tion which I had never met after closure without drainag

We have been more impressed by the results prevention of perforation than with the conservativ treatment after the catastrophe has occurred. B treating all cases of peptic ulcer with severe symptom as requiring urgent admission, and by accepting f surgical treatment all cases who we think are unlike to benefit permanently by medical treatment, we hav reduced the incidence of acute perforation by 44 during the last three years. Acute perforation in th York area has now become a rarity; the majority cases admitted are visitors to the district, transpo drivers, or passengers in trains. The few locals wh perforate "out of the blue" will always defeat ou efforts to anticipate, rather than wait for, this dreade complication.

York. A. HEDLEY VISICK.

PRICE OF POLYTHENE.—In his article of Sept. 14 (p. 38 Dr. Kent remarked that polythene costs about 1*s*. 2*d*. per Imperial Chemical Industries Ltd. point out that the minimu price of 'Alkathene,' the British grade of polythene the manufacture, is 3*s*. 3*d*. per lb.

SODA-LIME.—Already a familiar laboratory reagent, sod lime is now widely used in medical practice for the absorptio of carbon dioxide. Apparatus for closed-circuit anæsthesi oxygen therapy, and metabolism determination are a fe examples of its uses. Messrs. *Sofnol* Ltd., Westcombe Hil Greenwich, S.E.10, the makers of 'Sofnol Brand' soda-lim claim that their product possesses advantages such as con stancy of composition, high absorptive capacity, resistance t abrasion, and non-heating and non-deliquescent propertie Their catalogue, illustrated by easily understood graph describes in a simple way the experiments on which thes claims are based. These tests will be of interest to thos who are unfamiliar with the type of laboratory investigation to which a specimen of soda-lime must be submitted before it value as a CO_2-absorbent for medical purposes can be assessed the regional boards were to be permitted or obliged to delegate their powers.

[3] Topley, W. W. C., Wilson, G. S. Principles of Bacteriology and Immunity, 1936, pp. 1028–29.

Lord Jowitt admitted that the regulations did not yet exist, but pointed out that there would be opportunity to discuss them in Parliament. Broadly, the regulations would lay down that certain matters fell within the province of the management committees—for instance, the engaging and dismissal of staff, with the exception of senior staff. He did not suppose there would be an appeal to the board if the committee dismissed some servant. That would be interfering with the discretion of the committee unduly. He suggested that the new system whereby a nurse became a servant of the regional board, though she could contract to serve at a particular place if she liked, might lessen the recruiting difficulties of today.

Lord Inman, though he wished to see definite powers given to the management committee so far as this amendment was concerned, saw definite advantages in the Government's scheme. At his own hospital, to which several hospitals were affiliated, they had found that the nurses liked to move from one small hospital to another. Viscount Cranborne asked whether it would not be possible to distinguish between different types of staff. "Officer" was an all-embracing word. Could not the management committees control staff such as porters, who were unlikely to want to wander round the region? The amendment was negatived.

LOCAL-AUTHORITY SERVICES

Lord Addington moved an amendment permitting a county council on application from a borough to delegate to it functions relating to the care of mothers, young children, employment of midwives, health visiting, home nursing, vaccination, and so forth. The amendment also gave the borough council the right of appeal to the Minister if its application was refused by the county council. Lord O'Hagan moved further to extend the amendment to urban district councils. The amendment, Lord Addington declared, would provide a maximum of local control, attract voluntary effort, and permit the degree of delegation to vary according to circumstances. Lord Jowitt replied that in the past there had been a good deal of overlapping and confusion in the exercise of these functions, and their distribution was chaotic. Now that a new set of powers were being imposed on local health authorities, which it was hoped in the fullness of time would be performed at health centres, it was a matter of moment to entrust these duties only to major authorities, which meant the counties and county boroughs. The only exception was the care of children, which would follow the pattern imposed by the new Education Act. Lord Henley thought it would be unfair to the county councils to take away bits and pieces of their areas and spoil the continuity of their services. Viscount Cranborne thought that a proviso should be added to the amendment allowing delegation only subject to the approval of the Minister. To this suggestion the Earl of Listowel promised to give consideration, though he feared that even so the amendment would undermine the scheme for coördinating the services. The amendments were withdrawn.

METROPOLITAN BOROUGHS

Lord Balfour of Burleigh moved an amendment providing that the London County Council should delegate the functions cited in the last amendment to the metropolitan boroughs. Local government in London, he pointed out, was different from anywhere else in the country, and the functions relating to maternity and child welfare had never been exercised by the L.C.C. Over the past 50 years they had been delegated to the metropolitan borough councils, and the L.C.C. was still on record as being in agreement with that position. The boroughs had a very good record, and he did not think that under the Bill the services could be maintained at the same level of efficiency. But for the fact that London local government was a thing by itself, these great boroughs would have been made county boroughs long ago.

Speaking as a Parliamentarian, Lord Jowitt was not too much moved by the plea of an agreement reached between the L.C.C. and the borough councils outside Parliament. At the time of the agreement the L.C.C. were going to keep their [illegible]spitals, and presumably as they did not want to have too much on their plate passed these functions to the boroughs. Now the position was different and the L.C.C. felt that they had time to conduct these services themselves.

Lord Balfour thought Lord Jowitt had made an astonishingly good case considering he had not a leg to stand on, but with 25 years' experience as a borough councillor behind him he assured the House that they would spoil a good service if these functions were transferred to the L.C.C. The amendment was carried by 35 contents to 15 non-contents.

FROM THE PRESS GALLERY

When is a Nurse Not a Nurse?

On Oct. 14 in the Commons Mr. Alfred Edwards moved to annul the Nurses Amendment Regulation 1946. When the Nurses Act of 1943 was under discussion the Minister of Health, then Mr. Ernest Brown, in a letter, gave an assurance to the Christian Science movement that he would provide by regulation that nothing in the Act should prevent the using of the name or title of "Christian Science Nurse" by a member of the Church of Christ, Scientist, who was certified by the church to be qualified for employment as a nurse by members of the church. Had the movement not received this assurance they would certainly have moved an amendment to the Act. Nobody, Mr. Edwards declared, was entitled to claim a monopoly on a word or name. There were only 40–50 of these registered nurses in the country. No-one was allowed to practise as a Christian Science Nurse who had not completed 5 years' training and been recognised by the department. It would be impossible to engage a Christian Science Nurse in mistake for a medical nurse. Mr. G. Cooper, who seconded the motion, pointed out that the words "Christian Science Nurse" were used in the by-laws of the mother church in Boston, and even if the regulation went through it would be impossible to prohibit the use of the phrase in the literature issued by the movement.

Mr. Wilson Harris, though admitting he was no admirer of Mary Baker Eddy, supported the motion, for he was depressed by the high-handed action of those estimable people who wished to arrogate a common English word to their own purposes. He thought it reasonable to debar anyone from improperly using the term "registered nurse," but if in the phrase "Christian Science Nurse" the two Archbishops did not object to the use of the word "Christian," nor the Royal Society to the use of the word "science," why should anyone object to the use of the word "nurse"? Even the medical profession was less exacting, and the Chancellor of the Exchequer, though he could only pocket taxes and could not attack poxes, had the right to be termed "doctor." Mr. F. Messer pointed out that those interested in the question had had no knowledge of the correspondence taking place between Mr. Brown and the Christian Scientists, and he refused to be bound by an undertaking given by a Minister without consultation. The nursing profession was in dire need of recruits who he thought would only be gained if it won the status of a real profession. If the door were opened to the Christian Scientists it would have to be opened to everyone else.

Mr. A. Bevan explained that when he took office he was faced with a prayer to annul Mr. Brown's proposed regulation giving exemption to Christian Science Nurses. He therefore withdrew the regulation in the hope that a compromise could be reached. This had not proved possible so he had therefore introduced the present regulation. He admitted we were attempting to constrain the English language, but that happened whenever we made a charter and gave a specific meaning to a name. In the care of the sick, nursing, he ventured to suggest, was as important as any other branch of the medical profession. These women resented that after an arduous training they were known by a name which anyone could adopt. All the other exemptions to the Act were within the hierarchy of nursing itself. If he exempted the Christian Science Nurses where could he stop? He would have a stream of applications for exemptions and a great body of fine women would have been deeply and mortally offended. The motion was defeated by 245 votes to 43.

be strengthened, and Lord LISTOWEL agreed, for, he declared, the intention was that representatives of the local authorities should be included. The amendment was withdrawn.

The Earl of MUNSTER pointed out that the Bill had now been before Parliament for six solid months and asked whether the Government could not now give some information as to the size of the regions. Lord JOWITT said he wished he could but to be frank he could not. There was a great deal of negotiation to be done, and it would be foolish to attempt anything in a hurry.

FUNCTIONS OF THE HOSPITAL MANAGEMENT COMMITTEES

Lord LUKE moved an amendment seeking to readjust the functions of the regional boards and the hospital management committees by omitting the subsection particularising the duties laid on the boards—to appoint staff, maintain premises, and acquire equipment and furniture. Why, he asked, could not the hospital management committees have powers from the boards similar to those enjoyed by the teaching hospitals from the Minister? The committees would be formed of trustworthy people appointed by the Minister and be left to manage the affairs of the hospitals. The boards would have enough on hand planning their regions and generally giving guidance. To take the appointment of staff from the committees would raise difficulties of divided loyalties and remote control, and put the non-teaching hospitals at a disadvantage compared with the teaching hospitals. To have a floating population within the region capable of being moved at a moment's notice might make it difficult for a hospital to get and keep a team together. If the Minister wanted suitable people to become members of the committees he must give them suitable responsibility.

Lord JOWITT agreed that if people were to work on the hospital committees they must be given a real job to do. The issue was how to achieve this. The Government intended to prescribe by regulations that the hospital management committee should do all things in regard to the running of their hospital, but that they should do them on behalf of the regional board. The appointment of officers—except perhaps senior servants—should be in the hands of the committee, as would be all expenditure, other than the building of a new wing or anything of that sort. The Government expected that the committees would have wide powers covering practically everything except questions of major policy. But they thought it better not to impinge upon the principle that the regional board was the authority and the hospital management committee the agent acting on behalf of the board. If there were any dispute between the two the legal position would then be plain.

Lord LLEWELLIN thought that all would agree that as much power as was proper should be left to the committees. But in the Bill he felt it was being done in the wrong way. To get good men to serve, these committees must be made a reality and not just a kind of camouflage. Their responsibilities must be placed in the forefront of the shop window and not prescribed afterwards by regulation. Viscount SIMON pointed out that in the future these things would be construed not according to what had been said in the House of Lords but according to the language of the Bill: while laying particular duties on the regional boards, Parliament had not given the hospital management committees any defined duty. Under this clause it would be lawful for a Minister to say, "Oh, I do not think much of this hospital committee. I think on the whole that any regulations it may make should be subject always to the ratification of the regional board." The Marquess of READING suggested that it might be some time before the regulations dealing with the functions of the committees could be passed. Yet surely to enlist support for local hospital committees people should know at the earliest possible moment, in the clearest possible terms, and by the best possible instrument—which was the Bill itself—what the functions of the committees were to be.

Lord JOWITT replied that as part of a coördinated scheme the committees were to act as the agents of the boards. He was anxious that there should be no demarcation disputes and that the boards should have unquestioned authority. But he was equally anxious that the boards should exercise their powers by leaving a wide discretion to the committees. He would discuss the clause further with his advisers; but to keep the legal position clear he thought it should stand, though he hoped there would be such a wide measure of devolution as would satisfy the noble Lords.

Lord LUKE withdrew his amendment.

MEDICAL STAFF COMMITTEE

Lord MORAN moved an amendment that a separate house committee should be set up in each hospital in every group, and that each hospital should have a medical staff committee with a right to nominate members to the hospital management committees. The medical staff committee which flourished in all our voluntary hospitals was a unique instrument for keeping the hospital up to date in practical matters. But in municipal hospitals its place was taken by a single medical superintendent. Lord HORDER thought that the principle was vital but that the exact relationship between the committee and the management committee was a domestic matter. "If it is not the intention of the Minister to disallow the formation of medical staff committees, I think an assurance to that effect would be satisfactory."

Lord JOWITT said it was obvious that a hospital b[illegible] must be set up to run the individual hospitals under the jurisdiction of a hospital management committee; and save in rare cases, such as a fever hospital working with a general hospital, that would be done. It was also true that we must have medical staff committees, but he was reluctant to mention them in the Bill; for a good many committees would have to be set up—on nursing and dietetics, for instance—and if one were singled out it would look as if there were not to be any others.

In withdrawing the amendment Lord MORAN urged that it was important that in this matter municipal practice should be brought into accord with voluntary practice.

Lord MORAN moved a further amendment to provide that in teaching hospitals facilities for medical teaching and research as required by the university or medical school should be supplied. A bed in a teaching hospital might well be more expensive than in another hospital, and a time might come when a hospital used for teaching might be accused of extravagance. Professors of medicine and surgery throughout the country had signed a memorial on this point, for they felt that if the functions of the teaching hospitals were not put down on paper it might weaken their case later when they came to argue about the necessary provisions for carrying out teaching and research. Lord JOWITT agreed that besides the care of the sick the teaching hospital had an added function which might be even more important. He thought the amendment went a little too far, but he undertook to consider the matter with a view to drafting suitable words, and the amendment was withdrawn.

LEGAL STATUS OF HOSPITAL MANAGEMENT COMMITTEES

Lord LLEWELLIN moved an amendment to allow hospital management committees to sue or be sued. This was something, he asserted, that had to be settled at once for it could not be altered by regulation afterwards. Lord JOWITT recalled that the committees when acting as principals—in relation to research or in the administration of their own property—could be sued in the ordinary way. It was only when acting as the agents of the regional boards that they could not be sued. In a coördinated scheme there must be a chain of authority, and on this point he was not in a position to make a concession. The House accordingly divided, and the amendment was carried by 59 contents to 17 non-contents.

APPOINTMENT OF HOSPITAL OFFICERS

Lord LUKE moved an amendment enabling the Minister by regulation to empower the hospital management committees to employ officers other than specialists or consultants. The Earl of LISTOWEL stated that there already was power in the Bill to make a regulation of this kind. Lord MAUGHAM asked how the House could be expected to decide on this Bill when so much was left in the air to be determined by regulations. Why was there nothing in the Bill to show that the main management of the hospitals was confined to the management committee? The Marquess of READING asked whether ut in his day none existed. Years before the last war e anticipated its coming and its character better than ost of us, and recommended the provision of hospital helters. In 1939 he was due to retire, but instead he ndertook full-time administrative work in the E.M.S., here his time-saving orderliness and thoroughness stood is many medical "clients" in good stead.

Generous to his juniors, gentle and courteous to his ospital mothers, a hard worker in spite of indifferent ealth, he would push for others but never for himself, nd medical women owe him much for the doors he pened on their behalf.

"Those of us who worked with Owen," writes a colleague, "will always remember him for his keen insight into the problems which faced him, and his extraordinary sympathy and tact with little children. No trouble was too great when dealing with a patient, whether in hospital or in private, and the careful notes in his small, tidy but difficult handwriting, were a model of what case-taking should be. He had a valuable collection of clinical data, which the retiring nature of his character seemed to prevent him from publishing to any large extent."

His wife, who shared fully in all his interests, is left ith a son and daughter.

IAN MACKENZIE DAVIDSON

M.D. GLASG., F.R.C.S.E.

Dr. Ian Davidson, who died at Carlisle on Oct. 14 at the age of 30, leaves a gap that might have been made by many an older man, for he had packed much into his short life. The son of Mr. Norman Davidson, F.R.C.S.E., of Glasgow, he entered Glasgow University from Rugby and graduated M.B. in 1938. After holding a house-appointment in the Glasgow Victoria Infirmary, he went as ship's surgeon to the Far East. At the outbreak of war, he volunteered for the R.A.M.C., and after his discharge on medical grounds served as house-physician and house-surgeon at the Cumberland Infirmary, Carlisle, during 1940. The following year, after an interval during which he wrote his thesis on parkinsonism which was accepted for the M.D. degree in 1942, he returned to the Cumberland Infirmary as surgical registrar. While holding this post he obtained his Edinburgh fellowship, and in 1943 he was appointed assistant surgeon to the Infirmary, later becoming surgeon to the E.M.S., consulting surgeon to the Victoria Cottage Hospital, Maryport, and surgeon to the City General Hospital, Carlisle.

He was blessed with unusual gifts of mind and body, and his engaging charm and genuineness won him many friends. A sound surgeon, he had a deftness of hand that reflected a quick and steady brain, and the maturity of his judgment belied his youth.

His widow, Dr. Josephine Cartwright, D.R.C.O.G., of Edinburgh, and their year-old daughter, survive him.

T. McL. G.

HENRY HANNA

M.A., M.B., B.SC. R.U.I.

Mr. Henry Hanna, who died in Belfast on Sept. 28, was widely known throughout the Province, for generations of medical students had passed under his keen scrutiny, and he had a large private practice in diseases of the eye, ear, nose, and throat. For close on 40 years he had worked at the City Hospital, where he held the appointment of visiting ophthalmic surgeon at the time of his death. He retired from the staff of the Royal Victoria Hospital in 1939.

Born in 1874, he received his early education at Belfast Royal Academy while his university career was spent between Queen's College, Belfast, and St. John's College, Cambridge. The old Royal University of Ireland conferred upon him a B.A. in 1894, and two years later he graduated M.A., B.SC. In the following years he worked at Cambridge but he returned to Ireland to begin his medical course, and he took his M.B. in 1903. After holding a resident appointment in the newly built Royal Victoria Hospital, Belfast, and a demonstratorship in the department of anatomy, he spent some time in the eye, ear, and throat clinics of Vienna before returning to practise in his chosen specialty at Belfast. He served as president of the Irish Ophthalmological Society, the Ulster Medical Society, and his special section at the British Medical Association meeting in Belfast in 1937. But though he had held these offices with distinction he preferred his own fireside or the company of his friends whom he delighted with his dry wit.

"Outside medicine," writes J. R. W., "Hanna's interests were varied. He was often to be seen on the golf links, but perhaps his greatest joy was fishing in a quiet stream. He had a genuine appreciation of art and his collection includes many valuable pictures as well as a beautiful selection of porcelain and old Irish glass."

His widow survives him with two daughters.

Appointments

BEATTIE, W. M., M.CHIR. Camb., F.R.C.S.: assistant surgeon, David Lewis Northern Hospital Branch, Royal Liverpool United Hospital.

FRIPP, A. T., B.M. Oxfd, F.R.C.S.: consultant orthopædic surgeon, public health department, London County Council.

GUTTMANN, E., M.D. Munich, L.R.F.P.S.: assistant clinical director, Maudsley Hospital, Denmark Hill.

LEYS, D. G., D.M. Oxfd, F.R.C.P.: consulting pædiatrician, County Hospital, Farnborough, and North-West Kent.

LUCAS, B. G. B., M.R.C.S., D.A.: research assistant in anæsthetics, University College Hospital medical school, London.

MENDL, K., M.D. Prague, D.M.R.: radiotherapist, Swansea General and Eye Hospital.

SMITH, A. G., M.D. Glasg., F.R.C.S.: medical referee for dermatological cases under the Workmen's Compensation Act, 1925, for county court districts in circuits 32 and 33.

THOMAS, R. C., F.R.C.S.E., M.R.C.O.G.: consulting obstetrician and gynæcologist, County Hospital, Farnborough, and North-West Kent.

Examining Factory Surgeons:

BOWER, C. E. W., M.B. Vict., D.P.H.: Stretton, Cheshire.
CAMPBELL, A. M., O.B.E., M.B. Glasg.: Cumnock, Ayr.
GREGSON, A. H., M.B. Manc.: Cromer, Norfolk.
GUTHRIE, G. A., M.B. Glasg.: Nairn.
MACLEAN, R., M.B. Aberd.: Ullapool, Ross.
MORRISON, D. N. B., M.B. Glasg.: Braemar, Aberdeen.
WATSON, K., M.D. Dubl., F.R.C.S.E.: Redhill, Surrey.

Empire Rheumatism Council:

NICHOLSON, D. P., M.B. Lond., M.R.C.P.: registrar at West London Hospital.
SHIERS, DUNCAN, B.SC., M.B. Wales, M.R.C.P.: registrar at Roya Mineral Water Hospital, Bath.

Silicosis Medical Board: New Members

FREEBAIRN, N. A., M.B. Glasg.
PIERCE, J. W., M.D. Lond., M.R.C.P.
ROGERS, ENID M., M.D. Wales.
TURNER, G. E. M., M.R.C.S.
WILLIAMS, WYNDHAM, M.B. Edin.

Births, Marriages, and Deaths

BIRTHS

EVANS.—On Oct. 17, in London, the wife of Dr. John Evans—a son.

GARROD.—On Oct. 10, in London, the wife of Dr. Oliver Garrod—a daughter.

GIBBS.—On Oct. 12, at Mackenzie, British Guiana, the wife of Dr. D. S. Gibbs, of Hove—a son.

GLASS.—On Oct. 21, in London, Dr. Norma MacLeod, the wife of Dr. R. M. Glass—a son.

KERSHAW.—On Oct. 5, at Mansfield, the wife of Dr. Robert Kershaw—a daughter.

LAZARUS.—On Oct. 1, the wife of Dr. Samuel Lazarus, of Glasgow—a daughter.

O'CONNOR.—On Oct. 12, at Abingdon, the wife of Dr. G. F. O'Connor—a son.

ROSENVINGE.—On Oct. 12, at Harrogate, the wife of Dr. Gerald Rosenvinge—a son.

SMYTH.—On Oct. 17, at Brighton, the wife of Captain Greville Smyth, R.A.M.C.—a son.

THOMAS.—On Oct. 11, at Northampton, the wife of Dr. S. F. Thomas, M.B.E.—a daughter.

WHEELDON.—On Oct. 15, in London, the wife of Dr. F. T. Wheeldon—a son.

WOOLLEY.—On Oct. 18, at Derby, the wife of Dr. E. J. S. Woolley—a daughter.

MARRIAGES

ABRAHAM—CLARK.—On Oct. 15, at Aughton, Everard Cecil Abraham, M.C., M.D., to Doris Irene Clark, J.P.

BEAL—READE.—On Oct. 19, John Hugh Bruce Beal, B.M. Oxfd, F.R.C.S., to Mary Bettina Reade.

HILL—AKRED.—On Oct. 19, in London, Major Francis E. Hill, of Loxwood, Sussex, to Alice Akred, M.B.

READ—BRODIE.—On Sept. 25, at Penang, Malaya, Marten Turner Read, M.C., M.R.C.S., to Alison Garland Brodie.

THOMAS—GIRVAN.—On Oct. 17, at Pinner, David Francis Thomas, F.R.C.S., to Jean Isobel Girvan.

DEATHS

DAVIDSON.—On Oct. 14, at Carlisle, Ian MacKenzie Davidson, M.D. Glasg., F.R.C.S.E., husband of Dr. J. A. Davidson (*née* Cartwright).

HARRIS.—On Oct. 18, Henry Arthur Clifton Harris, M.R.C.S., of Appledram, Ditchling, Sussex, aged 73.

HOWIE.—On Oct. 14, at Eastbourne, Robert Howie, M.B. Glasg., aged 75.

PHILP.—On Oct. 13, at Preston Hall, Maidstone, James Daniell Philp, M.R.C.S., aged 29.

TURNER.—On Oct. 15, at Shirlett Sanatorium, Shropshire, Frederick Thomas Turner, M.C., M.R.C.S., medical superintendent.

Obituary

CHARLES SAMUEL MYERS

C.B.E., M.A., M.D., SC.D. CAMB., LL.D., F.R.S.

Dr. Myers, one of the first psychologists elected to fellowship of the Royal Society, died at his home near Minehead on Oct. 13. A few days earlier he had attended the celebration of the 25th anniversary of the National Institute of Industrial Psychology, of which he was founder and principal.

Charles Samuel Myers was born on March 13, 1873. From the City of London School he went to St. Bartholomew's Hospital for a year and thence to Caius College, Cambridge, of which he was later to become an honorary fellow. He won Foundation and Shuttleworth scholarships, and took a double first in the natural sciences tripos, but still found time to exercise his keen interest in anthropology and in music; and he himself played the violin expertly. He returned to St. Bartholomew's Hospital to complete his medical training, and soon after qualifying in 1897 he joined McDougall, Seligmann, Ray, Wilkin, and Haddon on the Cambridge University expedition to the Torres Straits and Sarawak. Myers's part was ostensibly to study native music, but his experience at this time coloured his subsequent work in psychology. On returning to this country in 1899 he took a house-appointment at Barts, but he soon abandoned clinical medicine. He remained in London, first as lecturer, and, after 1906, as professor of psychology, until in 1909 he returned to Cambridge as lecturer in experimental psychology and director of the psychological laboratory. In 1911 he became first president of the British Psychological Society, whose journal he edited until 1924.

Sport & General Press Agency

The first world war found Myers slightly over age for the R.A.M.C., but he went to France as a civilian and became a hospital registrar at Le Touquet. Soon he worked his way into the Army; he became consulting psychologist to the B.E.F., and also took a guiding interest in the training centre set up at Maghull, where instruction was given in the application of psychological principles to the war psychoneuroses. The emergency attracted the energies not only of Myers but of W. H. R. Rivers, Elliot Smith, and William McDougall—a band of scientists whose work had previously borne little relation to clinical medicine. They had an important share in opening up what was then a new field, and Myers himself contributed five articles to our own columns during the war years. He also carried out spare-time research for the Admiralty on the selection of hydrophone listeners. The pioneer's path, however, was not easy, and his book *Shell-shock in France, 1914–18* reflects the sense of frustration he experienced and his relief when his task could be relinquished.

The end of his active participation in medical psychology was marked by a vigorously controversial letter in THE LANCET of Dec. 27, 1919, in which he condemned physical interference in the treatment of hysteria.

> "It is high time that the medical profession should decide whether it is justifiable for a physician to tell lies to his patient with the object of effecting a cure by suggestion, and on the basis of such lies to perform a serious operation with that object. . . . During the war there were certain physicians who would explain to a patient suffering from functional hemiplegia that the cortical cells on one side of his brain were out of order. . . . And they would proceed to tone up the disordered cells by painful faradism. . . . I have always been convinced that such measures are not only needless, but also dangerous. If the patient is not cured by the electricity or the sham operation, his latter state is far worse than his previous one, because henceforth he firmly believes in an 'organic' basis of his condition. If, on the other hand, he is cured, he may at any future time fear or fancy a recurrence of his 'orga malady."

He had gained the F.R.S. in 1915, and on his return Cambridge had been eager to put his subject even mo clearly on the map. In 1920 he was promoted to readership; but he was denied the support he from scientists and philosophers, and on reflection decided to give up his academic life and to join with London business man, H. J. Welch, in the foundation the National Institute of Industrial Psychology. He he found scope for his abilities in his successful teachi that the humanising of industry by study of the worke comfort, the adjustment of working conditions, and th fitting of the right man to the right job could be carri out only with the aid of psychology.

Mr. Alec Rodger writes: "The National Institute wa Myers, and Myers was the National Institute; but it may be questioned whether he was altogether happy in his new life. In some ways he relished his constructive task, but now he had little time for teaching, and very little more for research. Moreover, the support he obtained from industry was scant. He became too preoccupied with financial problems and relationships with other bodies, public and private, to be able to give as much attention as he wished to science. Some consolation he undoubtedly gained from his editorship of the National Institute's journal, *Occupational Psychology*, but it seems likely that in London as in Cambridge he suffered disappointment. Nevertheless, he made his outstanding mark, and it gave him satisfaction to know that most of the personnel selection procedures adopted by the Navy and Army in the second world war, in the initial selection and allocation of recruits, were based directly on those developed by the institute for civilian purposes. He was a cultured, generous, kindly affectioned man, proud of his Jewish race. It is fitting that his last production should have been a report on Attitudes in Minority Groups, prepared for the Society of Jews and Christians: it is a fine, scholarly work which reflects his deep insight into anthropology."

Myers published an *Introduction to Experimental Psychology* and other books mostly concerned with the industrial aspect of psychology, but his influence was exerted rather through his teaching and organising tha his writings. In later years he was honoured by sever universities, receiving, honoris causa, the D.SC. of Manchester in 1927, the LL.D of Calcutta in 1938, and th D.SC. at Pennsylvania in 1940. He lived to see th successful application of principles established thirt years ago by him and his colleagues.

He was married and had two sons and three daughter who, with his widow, attended a memorial service London on Oct. 16.

SYDNEY ARTHUR OWEN

M.D. CAMB., F.R.C.P.

Dr. Sydney Owen had been at heart a children doctor since the days when he served as resident medic officer at Shadwell, and though he did not drop his wor among adults his appointments showed where his rea interest lay. A pioneer in neonatal pædiatrics, he ha been physician to the Queen's Hospital for Childre Hackney, since 1910. Physician to the Princess Loui Hospital for Children from the time of its opening, he wa also on the staff of the City of London Maternity Hospita From 1912 to 1937 he was in charge of the pædiatr department of the West London Hospital, where he die on Oct. 14.

An exhibitioner of Trinity College, Cambridge, he too a first class in the natural sciences tripos in 1901. A University College Hospital, where he qualified in 190 taking his M.B. the following year, he was awarded a Atchison scholarship, a senior Fellowes medal, and medal for midwifery. In 1910 he took his M.D. Camb., an in 1928 he was elected F.R.C.P.

Among the pieces of apparatus which he introduce and carefully tested was the "oxygen bell," a devic for administering oxygen to small infants which is i regular use in hospitals. But it was characteristic o Sydney Owen that he himself never published anythin about its use. An excellent teacher, he would have fille admirably a full-time clinical and academic appointment

ROYAL COLLEGE OF SURGEONS OF ENGLAND

MONTHLY dinners to which fellows and members of the llege and members of the associations linked with the llege may bring guests have now been held for just over a ar, and the attendance has ranged from 40 to 100. The nners always take place at the college on a Wednesday, 7 P.M., and the following are the dates chosen for the ming session:

1946: Nov. 13, Dec. 11.
1947: Jan. 8, Feb. 12, March 12, April 9, May 7, June 11, July 9.

Applications for tickets, accompanied by a remittance of ne guinea a head, must reach the assistant secretary of the ollege, Lincoln's Inn Fields, London, W.C.2, at least one week efore the date of the dinner.

ADDITIONS TO POISONS LIST

BY regulations which came into force on Oct. 15, pethidine nd its salts, and dihydrodesoxymorphine are added to part I f the Poisons List, and zinc phosphide to part II. These ubstances are added to the first schedule of the Poisons Rules, but rat and mouse poisons containing zinc phosphide re exempted from first schedule requirements and may be ld by listed sellers of part II poisons.

niversity of Sheffield

Dr. D. H. Smyth has been appointed to the chair of physiogy, in the place of Prof. G. A. Clark, who has resigned to ake a post in the Ministry of Health.

Dr. Smyth, who is 38 years of age, graduated B.SC., with first-lass honours, at Belfast in 1929, and M.B. in 1932. After being house-surgeon at the Royal Victoria Hospital, he was, in 1933, ppointed senior demonstrator in physiology at Queen's University, where he worked under Prof. T. H. Milroy and Prof. Henry Barcroft. In 1934 he became a M.SC., and in 1935 M.D. With a Musgrave studentship he studied for a year under Prof. Hermann Rein at Göttingen, and on returning to this country in 1937 was appointed ecturer in physiology at University College, London. In 1939 Dr. Smyth went to Sheffield to which part of the London Faculty f Medical Sciences was evacuated, and in 1940 he helped to organise he department's work at Leatherhead; in 1944–45 he acted as ead of the department in the absence of Prof. Lovatt Evans, .R.S., on special war duties. In 1941 he gained the doctorate f philosophy of London University. Since 1943 he has been sub-ean and tutor to medical students at University College, and as made a special study of methods of selecting candidates for raining. This year he became senior lecturer in physiology. His ublications have dealt principally with respiration and metabolism.

As announced last week, Dr. R. S. Illingworth has been ppointed professor in charge of the new department of child ealth in the university.

Dr. Illingworth studied medicine at the University of Leeds, ualifying in 1934. He held resident medical posts at Leeds, and bstetrical and ear, nose, and throat posts at Huddersfield, and pent a period in general practice before appointment as resident nedical assistant and clinical pathologist at the Hospital for Sick hildren, Great Ormond Street. He graduated M.D. and became .R.C.P. in 1937, and in 1938 obtained the D.P.H., with distinction, and he D.C.H. In 1939 he won a Nuffield research studentship in medicine t the Radcliffe Infirmary, Oxford, and a Rockefeller research ellowship for travel in the United States. He was in the R.A.M.C. rom 1941 to 1946, serving, with the rank of lieut.-colonel, as fficer in charge of the medical division of military hospitals in the iddle East and Northern Ireland. He is at present assistant o the professor in the Institute of Child Health, London. Dr. llingworth has published papers on nephritis, prematurity, infectious iseases, and other subjects. He is a fellow of the Royal Photographic ociety.

niversity of Manchester

On Tuesday, Nov. 19, at 4.15 P.M., Prof. Michael Polanyi, .D., PH.D., F.R.S., will deliver the Lloyd Roberts lecture in he physiology theatre of the university. Professor Polanyi, ho holds the chair of physical chemistry at Manchester, will eak on the Foundations of Academic Freedom.

oyal College of Surgeons of England

On Oct. 15 Dr. Allen Oldfather Whipple, Valentine Mott rofessor of surgery at Columbia University, New York, was dmitted to the fellowship, honoris causa, and was afterwards ntertained to dinner by the council. In the course of his peech of presentation, Sir Heneage Ogilvie, senior vice-resident, described him as "a great American surgeon, a ioneer in surgical research, a moving spirit in surgical education, a brilliant operator, an inspiring writer, a well-loved eacher." He went on:

"We honour him, not for his many distinctions but for the ability hat earned those distinctions, not for the many important offices e holds or has held but for the outstanding qualities of mind and haracter that have earned him those appointments. Dr. Whipple's ame is printed large on every page of surgical advance, and where ther surgeons are breaking new ground and treading fearfully as hey are today in the surgery of malignant diseases of the pancreas, here they see Allen Whipple before them saying 'Here I am. This s the way I have gone, and where I have trodden, you may follow afely.'"

Royal College of Surgeons of Edinburgh

At the annual meeting of the college on Oct. 16 the following office-bearers were elected for the ensuing year: president, Mr. J. M. Graham; vice-president, Prof. R. W. Johnstone; secretary and treasurer, Mr. K. Paterson Brown; members of the president's council, Sir John Fraser, Dr. G. Ewart Martin, Mr. F. E. Jardine, Mr. W. Quarry Wood, Mr. Walter Mercer, and Prof. J. R. Learmonth: representative on the General Medical Council, Sir Henry Wade: convener of museum committee, Mr. W. Quarry Wood; and librarian, Dr. Douglas Guthrie.

The following were admitted fellows:

Nicholas Alders, M.D. Vienna, M.R.C.S.; C. J. B. Anderson, M.B. Aberd.; W. G. Birks, M.B. Adelaide; S. K. Burcher, M.B. N.Z.; A. G. S. Calder, M.B. Edin.; E. A. Chisholm, M.B. Glasg.; L. M. David, M.B. Witwatersrand; F. W. T. Davies, M.R.C.S.; A. J. Freese, M.R.C.S.; G. L. Gale, M.B. Birm.; M. P. Goradia, M.B. Bombay; J. B. M. Green, M.R.C.S.; F. M. Hanna, M.B. Dubl.; E. L. John, M.B. Lond.; W. G. Kerr, M.B. Edin.; J. E. Laing, M.B. Edin.; W. H. S. Liebenberg, M.D. Amsterdam; Tobias Levitt, M.R.C.S.; A. A. MacGibbon, M.B. Edin.; J. M. McInroy, M.B. St. And.; T. B. McMurray, M.B. Lpool; J. M. Matheson, M.B. Edin.; K. N. Mitra, M.B. Patna; R. F. O'Driscoll, M.B. N.U.I.; G. V. Osborne, M.B. Lpool; A. P. R. Pinto, M.B. Bombay; E. C. Richardson, L.R.C.P.E.; G. K. Riddoch, M.B. Camb.; L. J. Roy, M.B. N.Z.; A. R. Taylor, M.B. Aberd.; D. J. Waterston, M.B. Edin.; Austen Young, M.B. Edin.

Royal College of Physicians of Ireland

Dr. Bethel Solomons has been elected president of the college.

Royal College of Obstetricians and Gynæcologists

The following course of lectures on recent advances affecting obstetrical and gynæcological practice will be given in the college house at 5 P.M. on each day: Nov. 1, Prof. J. C. Moir, Application of Radiology to the Diagnosis of Cephalo-pelvic Disproportion; Nov. 15, Dr. J. M. H. Campbell, Heart in Pregnancy; Nov. 29, Dr. J. F. Loutit, Rhesus Factor; Dec. 13, Mr. Victor Bonney, Myomectomy; and Jan. 10, Mr. F. J. Folley, D.SC., Lactation. Admission is by ticket only, for which early application should be made to the secretary.

Leeds and West Riding Medico-Chirurgical Society

Forthcoming lectures to this society include: Nov. 1, Prof. H. V. Dicks, Rôle of the Family Doctor in Mental Hygiene; Nov. 22, Dr. Macdonald Critchley on Sir William Gowers; Feb. 14, Dr. Peter Bishop. Use of Sex Hormones in Medicine; March 8, Prof. C. F. W. Illingworth, Recent Observations on Peptic Ulcer.

Association of Plastic Surgeons

A meeting of those interested in the establishment of an association of plastic surgeons will be held at the Royal College of Surgeons, Lincoln's Inn Fields, W.C.2, on Wednesday, Nov. 20, at 5 P.M. The President of the Royal College of Surgeons, welcoming the formation of such a body, has suggested that it should fall into line with similar associations already affiliated to the college.

Gifts from South Africa

General Smuts, prime minister of South Africa, on Oct. 18 handed to Mr. Attlee a bank draft for £196,000 as an offering to the people of Great Britain from the people of Durban and the province of Natal. Attached to the gift was a condition that the money should be spent on a hospital or similar utilitarian memorial. At the same time General Smuts presented a gold certificate for £985,000 as a nation-wide offering from all the people of South Africa and the British protectorates "to be used for the advantage of the British people."

Empire Rheumatism Council

Today, Friday, Oct. 25, Dr. C. W. Buckley will take the chair at a dinner, to be held at the Euston Hotel, London, N.W.1, at 7.15 P.M., to welcome the official Swedish delegates to the celebrations of the tenth anniversary of the foundation of the council. On Oct. 26, at 11, Chandos Street, W.1, at 11 A.M., Prof. J. A. Höjer, chief medical officer of the Royal Swedish health department, will give an address on Organisation of Treatment and Research into Rheumatism in Sweden. Lord Horder will be in the chair, supported by Mr. M. G. B. Prytz, the Swedish minister. On Monday, Oct. 28, at 4 P.M., Mr. Aneurin Bevan, the Minister of Health, will be present at a reception to be held at the Apothecaries' Hall, Black Friars Lane, E.C.4. On Oct. 29, H.M. Government will give a lunch at the Savoy Hotel at 1.15 P.M., when Mr. Bevan presides; and at 5.30 P.M., the British Council are to hold a reception at 74, Brook Street, W.1.

Notes and News

LIVERPOOL MEDICAL INSTITUTION

AT a large gathering of members of this institution, held last Saturday, with Dr. G. F. RAWDON SMITH, the president, in the chair, the honorary membership was conferred on Dr. A. E. Barclay, Sir Allen Daley, Dame Louise McIlroy, Prof. Charles McNeil, Dr. Ivan Magill, and Sir Alfred Webb-Johnson. The following are extracts from the introductory speeches delivered by Dr. ROBERT COOPE as orator:

DR. ALFRED ERNEST BARCLAY

In medicine's house there are many mansions. Alfred Ernest Barclay is one of the pioneers who has helped to build its well-fitted darkroom, in which men can usefully pursue "shadows, not substantial things." He has given us the work of a master in his book on the radiology of the digestive tract. With rare ingenuity he divides light from darkness, and emerges from obscurity to explain the mechanism of swallowing or to reveal the mysteries of the fœtal circulation, or to startle us with a new and revolutionary tale of the blood-flow through the kidneys. Thus he looks upon the forms of things unknown, turns them to shapes, and gives to airy nothing a local habitation.

To craftsmanship he adds a scholar's integrity. . . . As Socrates felt about words, so he feels about X-ray shadows: to use them in an improper sense is not only a bad thing in itself, but it also generates a bad habit in the soul.

SIR ALLEN DALEY

William Allen Daley—one of our own sons, a former councillor of this institution—has wandered into a far country, but today he comes back to us, full of honour and achievement.

There is no problem of preventive medicine on which the Government of the day does not turn to him for counsel. He sits almost by natural right on committees and commissions which consider matters of medical administration, education, or policy. Since 1939 he has directed the health services of the County of London—that awkward, more than ever ungainly Great Wen. But London has no terrors for this Merseysider. The man who was brought up in Bootle, who married a native of Liverpool, whose children were born in our midst, who thrived on the smoke and noise of Brownlow Hill, and who was tempered in the keen air of a provincial medical society could take London in his stride.

Throughout the war years, when London endured the long-drawn-out sufferings of bombs and fire and flying bombs and rockets, he virtually never left his post, day or night. The calm and sustained devotion to duty of this modest and homely man steadied and inspired his team. We welcome him home with pride.

DAME LOUISE MCILROY

"England," wrote Bernard Shaw, "cannot do without its Irish and its Scots, because it cannot do without at least a little sanity." Anne Louise McIlroy made doubly sure that we should need her, first by being born in Antrim, and then by taking her medical course in Glasgow. It wanted only the finishing touch of Dublin to make her irresistible when the Royal Free Hospital looked for a professor of midwifery.

She might sweep through her ward like a whirlwind: might on occasion drive her staff almost to distraction by an inexorable insistence on detail: might never hesitate to say, forcibly and without respect of persons, what was in her mind; but however wild an Irishman may be, he has one eye always on things as they are. To many problems in her chosen field she brought abounding enthusiasm, but her final answers had the simplicity of hard common sense. Her old students have found that she has fixed enduringly in their minds fundamental principles. She has even dared to preach that the right place for a baby is with the mother. . . .

Now in the ripeness of her days, she can look back upon old, forgotten, far-off battles, and be satisfied: for by what she has done and by what she is, she has helped to make it natural for women to take their place in our profession.

PROF. CHARLES MCNEIL

Early in his medical career Charles McNeil was hard-headed enough to realise that much may be made of a Scotsman if he be caught young. Certainly a lifetime's experience of techy and wayward infancies has made him a canny clinician and a very wise man, a senator among pædiatricians: nor has it taken the edge off a dry and palatable humour.

He has thrown light on many aspects of disease in children, notably on the respiratory infections of childhood; but as professor of child health he *more than most men has given to pædiatrics* a positive social content, championing the cause of the newborn baby, pleading earnestly for prophylactic child-care. To him this is no affair merely of instruction at medical clinics. He wants a practical and practisable gospel of child welfare carried right into the homes of the people.

We hope that it may be long before he needs an epitaph. When the time comes, however, he will have well earned that which was once given to another great man: "When he died, the little children cried in the streets."

DR. IVAN MAGILL

Ivan Whiteside Magill came across the water from Northern Ireland bringing with him a rich brogue and a spirit eager to blaze new trails. For a brief moment he broke his journey at our own Stanley Hospital to familiarise himself with a special brand of catarrhal upper respiratory tract; but he passed on to the metropolis, where he now puts even the most uneasy of crowned heads to sleep.

Modern anæsthesia owes him much, for he has improved its techniques and helped to make it safe. Without his skill and guidance the thoracic surgeon especially might still be unable to move delicately and with little hazard in a difficult field. Today the patient condemned to a chest operation is not even allowed to breathe; his respiratory centre is first poisoned and then ignored, and with rubber bag and strong right hand the anæsthetist breathes for him. Moreover, Magill has seen to it, by the provision of ingenious tubes, that the anæsthetising vapours are carried to the innermost shrine of his being.

SIR ALFRED WEBB-JOHNSON

The glory of a surgeon is a thing of a moment: he lives so long as he is alive. The quick and ready motion of st hands with experience creates his signature, which no man copy; and though it may be read on the bodies of his p they too are mortal.

Some surgeons live on in their students, lighting a cand their minds and hearts which can never be put out. Some numbered among the few who in various ways help to push fo the advancing edge of their subject. Some are remembered their leadership in wider issues of medicine and of medical p

Alfred Webb-Johnson qualifies on all three counts. W Manchester trained one day, London received a little breathle on the morrow. A born teacher, he never forgets a studen houseman, a theatre sister, a nurse who has been one of his te he even knoweth his sheep by name. Medical education a research have profited by the magic of this modern alchemist w has solved the mystery of distilling gold from baser metal. A now he is one of our most trusted medical statesmen, a man for t times, clear headed, robust in common sense, imperturbable.

After the new honorary members had been formal admitted by the president, each expressed appreciation and thanks to the members. In the evening the honorar members, together with the Lord Mayor of Liverpool and other official guests, were entertained to dinner at the Exchange Hotel.

COUNCIL FOR THE CARE OF SPASTICS

THE founding of St. Margaret's School at Croydon[1] ha marked an entirely new phase in the care of children with cerebral palsy in this country. Their special needs are now recognised, and for some time various people and bodies interested in their care have felt that a council should be formed on a national basis to provide treatment and education for them. On Oct. 17 a meeting was held at the London School of Hygiene and Tropical Medicine, with Mr. G. R. Girdlestone, F.R.C.S., in the chair, to consider how such a council might best be founded. Both the Central Council for the Care of Cripples and the British Orthopædic Association, he said, have been studying the needs of these children. The Ministries of Health and of Education have included them in their plans in a general way, but there is much more to be done, he feels, in exact diagnosis of the damage done to the brain, and in the study of the psychological needs of spastic children. About a twentieth of them are deaf or have defective hearing. The exact numbers in the country have yet to be ascertained, but there are said to be about 7 children born with cerebral palsy in every 100,000 live births; 1 of these will die during infancy and 2 of the remaining 6 will be seriously defective mentally and thus fall outside the group for which the proposed council is to care. Each child needs the attention of an orthopædic surgeon, and Mr. Girdlestone estimated that there should be one physiotherapist and one occupational therapist for every 15, and a speech therapist for every 30 children. The parents need training in the care of their children; at St. Margaret's the mother is is to spend a day at the school once a week, helping to look after both her own child and others. The council, Mr. Girdlestone suggested, must help to develop training institutions, including residential and day schools, vocational training centres, and perhaps sheltered factories. In Danish hospitals, it seems, 30% of the secretarial staff are cases of cerebral palsy, a plan which does well, he said, as long as those they have to work with remain calm and serene. Since the only way to convince people that a thing needs doing is to do it, he suggested that the council, when formed, should select a small energetic committee to get the work going. A discussion on the name of the council followed, in which it was agreed that the work should not be limited to children, and that an appropriate name would be "Council for the Care of Spastics (and those with allied conditions)."

Prof. J. M. Mackintosh was anxious to see the council formed forthwith, but since many of those present were unknown to each other it was finally agreed that the meeting should constitute itself an Association for the Care of Spastics (and persons suffering from kindred conditions), and should appoint a committee to draw up recommendations for the creation of a council. This committee, it was agreed, should have power to receive and expend money until they reported to the association in six or eight weeks' time, and their running expenses for that period, up to £400, were guaranteed by Mr. Paul Cadbury.

Members of the committee are: Mr. Stephen K. Quay (chairman); Mr. H. P. Weston, M.A. (secretary); Mr. E. S Evans, F.R.C.S.; Miss M. I. Dunsdon, M.A.; Mrs. W. Lionel Hitchens; and Mr. N. D. Bosworth Smith, M.A.

From the National Institute for Medical Research, London

THE possibility of a widespread influenza epidemic in e winter 1945–46 was a serious problem to public-alth authorities in this country and on the Continent, d there was the more remote prospect of a pandemic ch as broke out in 1918–19. Conferences were therefore ld in 1945 under the auspices of the Medical Research ouncil to discuss methods of control of an epidemic, ould one develop.

It was thought important that any increase in the cidence of upper respiratory infection should be etected as early as possible, and that every attempt ould be made to isolate and identify any influenza irus in order to compare its antigenicity with known trains. A careful watch on the weekly influenzal deaths n the 126 great towns of England and Wales and the nortality in the younger age-groups would give addi-ional information about the trend of the epidemic.

A circular letter from the Ministry of Health (E.M.S.I. 526) was sent to many hospitals and medical officers of this country asking them to report any increase in upper respiratory infection and in influenza, and to submit samples of serum for serological test and garglings for virus isolation. The conditions in Western Europe, particularly the shortage of food and fuel, together with the continually shifting population of displaced persons, made the spread of communicable disease a very real threat there, and all medical officers in the army of occupation and civil administration were therefore asked to coöperate in this "spotting system" by reporting the number of cases of influenza in their areas.

An epidemic did break out and was proved both serologically and by direct virus isolation to be largely due to the B virus. The first indication of influenza came in late December, 1945, from military hospitals in Brussels and Antwerp; virus B was identified serologically in several cases. Despite this and mild local epidemics in a few units of the British Army of the Rhine (B.A.O.R.), there was no general epidemic in Germany. A most careful watch for cases of influenza was kept in the U.S. zone by the medical services of the U.S. Army; and, though sporadic cases, proved to be influenza A or B, were encountered among U.S. troops, no epidemic developed either in them or in civilians.† Some displaced persons' camps, which were under special observation, did not have epidemics, though sporadic cases of influenza A and B were encountered.

INFLUENZA OUTBREAK IN GREAT BRITAIN

The deaths from influenza reported weekly from the 126 great towns of England and Wales began to increase in the second week of December and rose in irregular fashion to a peak in the last week of January and first week in February, after which a slow decline began (table I). However, the increase in deaths was not uniform all over the country, and some areas, including East Anglia and the West Country, did not register any considerable increase. By comparison with other recent epidemics, that of 1946 was moderately severe; but actual outbreaks or epidemics among either the population or in semi-closed communities were not encountered except in the instances detailed below. Practitioners of the East Midlands, who were circularised by the Ministry of Health, recorded outbreaks in some areas but not in others. Absenteeism from the industrial areas was not regarded as unusually high.

The chief evidence which supported the statistical record of an epidemic was the reception of numbers of sera, usually from 2–5 individuals from each of numerous hospitals, from cases in patients or staff regarded as typical of influenza. The rate of reception of specimens in the various weeks rose to a peak which coincided in time with the statistical record of deaths (see figure). Notified influenza morbidity in the Army at home, though of low total incidence, also showed a rise which coincided in time with the deaths and the numbers of specimens. Similar notifications for the B.A.O.R. did not show this rise as compared with figures for December, 1945.

Epidemics encountered during this time included several sharp outbreaks at public schools and preparatory boarding-schools in the south of England. These schools reassembled about Jan. 17 and had an incidence of 20–50% of cases of influenza within the next three weeks. A small outbreak at a tuberculosis convalescent home at Harrow began on Jan. 17. An "epidemic in miniature" occurred from Jan. 25 to Feb. 9 in two companies of Army recruits at Colchester among units of infantry training centres assembled on Jan. 18. Two outbreaks of influenza in the R.A.F. among West Indian troops (see below) occurred in the early days of January and at the end of that month. The striking feature of the Service outbreaks was their localisation to a certain type of population and failure to spread to neighbouring companies or units. The absenteeism from the very large number of workers at Woolwich Arsenal reached a maximum in the third week of January. In general therefore the outbreak occurred in Great Britain in January and early February, with a peak in the week ending Feb. 2.

SEROLOGICAL INVESTIGATIONS

From late December to the end of April, 1946, 351 pairs of sera from the United Kingdom and British

Medical Research Society

A lecture on the Artificial Kidney will be given by Dr. W. J. Kolff at University College Hospital medical school on Thursday, Nov. 7, at 5 P.M. Those interested are invited to attend.

Radiotherapy in Uterine Cancer

A joint meeting of the British Institute of Radiology, the Faculty of Radiologists, and the radiological section of the Royal Society of Medicine will be held today, Friday, Oct. 25, at 5 P.M., at the institute's house, 32, Welbeck Street, W., to hear Prof. J. Heyman (Stockholm) speak on Radiotherapy of Cancer of the Corpus Uteri.

Professional Nurses and Midwives Conference

At the opening of the conference in London last Monday, Colonel Walter Elliot, F.R.C.P., F.R.S., the deputy president, traced the history of British nursing since it had broken with the European tradition of association with religious foundations. Florence Nightingale, he said, though she achieved the miracle of a ready-made tradition, was herself a rebel. Even before the start of the late war there had been too few nurses; he blamed overwork and underpay, and the deadening effect of tradition. Registered nurses now numbered 138,000, and it was estimated that a further 30,000 nurses were required—*i.e., three years' intake without allowing for the 50% wastage.* Better conditions were needed, with a modernisation of the tradition, but the nurse's authority must be retained; the nursing profession must, above all, preserve its charity and discipline.

London Hospital Dinner

Presiding over the annual dinner on Oct. 17, Sir Henry Bashford pointed out that in the nine years since it was last held a whole generation of students had entered the hospital, qualified, held house-appointments, and gone its way. These years had seen the death of many members and former members of the staff—Mansell Moullin, Hurry Fenwick, Wilfred Hadley, Percy Kidd, Henry Head, Lord Dawson, Hugh Rigby, L. A. Smith, H. R. Andrews, Lambert Lack, E. W. Clapham, James Sherren, William Bulloch, Charles Miller, Russell Howard, S. G. Scott, F. F. Muecke, Charles Lindsay, Jack Harris, and Tudor Edwards—and of Sir William Goschen, the chairman. Of the many retirements he mentioned only two—those of Prof. Arthur Ellis to the regius chair of medicine at Oxford, and of Mr. E. J. Burdon, whom he had supposed to be part of the fabric but who had in fact been secretary to the medical school for only 37 years and was still young enough to embark on some entirely new occupation such as farming or holy orders. During the war 1206 Londoners (including nurses and lay staff) served in the Forces, winning 73 decorations and 83 mentions in despatches. Consultants in the three Services included Robert Milne, Alun Rowlands, Henry Tidy, James Walton, Hugh Cairns, J. R. Rees, George Riddoch, Ashley Daly, Charles Donald, Arthur Lister, R. R. Bomford, and W. J. O'Donovan. Baronetcies had been conferred on Robert Hutchison and Hugh Lett, who were simultaneously president of the Royal Colleges of Physicians and Surgeons. Dr. Dorothy Russell and Dr. Clifford Wilson were now professors, and the appointments to the hospital staff included those of Sir Reginald Watson-Jones, Mr. Osmond Clarke, Mr. Vaughan Jackson, Dr. Frank Ellis, Dr. Lloyd Rusby, Dr. Kenneth Perry, Mr. Vernon Thompson, Dr. Henry Wilson, and Mr. A. Bowen-Davies: the London had never believed in the closed shop. There were new departments for X-ray therapy, psychiatry, and the treatment of accidents: thanks to rehabilitation "a man coming in with a fractured femur can be discharged a fortnight later as a fully trained organ-grinder." Rebuilding plans would cost £3 million, and £100,000 was already being spent on repairs to the hospital, which had had eight direct hits. With 620 beds in use in London and 320 in the annexe at Brentwood, it was still (as throughout the war) the largest voluntary hospital in Britain.

In the medical school, said Sir Henry, women would appear in October, 1947; and he welcomed among the guests Colonel C. R. M. Green, I.M.S. retd., who became a student there in 1879 and had now entered his grand-daughter. To those still having trouble with examinations he offered the comfort of long experience: "either you go on and on and on—or you don't. And as one looks at time from the other end, how little it seems to matter." Looking at the men the hospital had produced he could not feel too pessimistic about the future of medicine. After all, in the golden age of Mead, Arbuthnot, Radcliffe, and Hans Sloane, physicians considerable part of their income by selling remedies composition they often kept secret; and a hundred hence some of the customs of our own time might equal thought inappropriate. Medicine itself, as art and went too deep to be ever chained or bridled by enthusiasts of whatever persuasion. The same was the London Hospital, which represented something too and too sane ever to disappear. In the future as in the each new generation coming within its influence would its tradition.

Dr. J. H. Thomas, proposing The Chairman, quoted of his early poetry. While disputing a statement in one of his less good books Dr. Thomas felt bound commend his steadfastness and his humanity.

Diary of the Week

OCT. 27 TO NOV. 2

Monday, 28th

UNIVERSITY OF LONDON
5.30 P.M. (London School of Hygiene, Keppel Street, W.C.1.) Major Greenwood, F.R.S.: British Pioneers in Medicine from Percival to Simon. (Heath Clark lecture

BIOCHEMICAL SOCIETY
11.15 A.M. (London School of Hygiene.) Discussion: Quantitative Biochemical Analysis by Microbiological Response.

noted on the second amniotic passage but was not present on the third; these were classed as negative (see table III). The first 2 cases in which virus was isolated occurred in January, one from a patient in Germany, the other from a nurse in Surrey with a severe form of influenzal pneumonia. Specimens of amniotic fluid (second amniotic passage) were tested against specific A and B ferret antisera. The virus was inhibited by B (Lee) serum but not by A serum; the current virus was therefore a B virus.

Until the first isolation in January 18 garglings had been tested with negative results. After this, more successful results were obtained, and this increase in the number of cases in which virus was isolated coincided with the increase in the recorded number of deaths from influenza. Though several of the earlier garglings were taken from patients who were later shown serologically to have had influenza, it was impossible to isolate the virus from these garglings, and repeated attempts to isolate the virus from material stored at −76° C failed. A possible explanation is that the virus underwent some change during human passage which made its isolation easier.

All strains isolated were readily adapted to growth in the allantoic sac. Using third amniotic passage material, 0·1 c.cm. was inoculated into the allantoic cavity of 10-day chick embryos. The fluid was harvested after 48 hours and its agglutinating titre tested by Hirst's method. The twelve positive strains were regarded as distinct until they had been compared antigenically one with another and with other known strains. Owing to the number involved it was impossible to proceed with them all.

ANTIGENIC COMPARISON

An early attempt was made to compare the current strains with previously isolated B strains, the standard B (Lee) strain and the Paddington strain. Two recent strains, Eliz B and Mil B from an epidemic in Melbourne in 1945, were sent to England by air by the kindness of Dr. F. M. Burnet.

Specimens of allantoic fluid from each of the five strains—Lee, 4 current strains, Paddington, Eliz B, and Mil B—were inoculated into ferrets for the production of specific ferret antiserum. Owing to the difficulty experienced in adapting the current strains to mouse lung (see below), the only attempt at antigenic comparison was by Hirst's test. Table IV shows the comparison between the Lee and four of the current strains, CRA, LEI, CLE, CLA. These four appeared to be distinct from Lee but to be themselves closely related. There was no relation to the A virus. Table V shows a further analysis of several different B strains with their respective ferret antisera. It can be seen that the Lee and the remainder, except possibly the Paddington, are distinct; there appears to be a fairly close connexion between the CRA, Eliz B, and Mil B, though there are possibly some small antigenic differences in the remainder of the subgroup. There is some tendency, also noted by Francis et al. (1946) in the case of rabbit sera, for freshly isolated B strains to be very susceptible to agglutinin inhibition by heterologous and even normal sera.

In view of the differences between Lee and 1946 strains, human sera showing no antibody rise against Lee were retested against the CRA strain. For example, of 10 sera tested from a small epidemic at a school in Dorset, 5 were positive to B (Lee) and 5 negative to A and B. When these sera were retested with the current strain (CRA), 2 of the negative sera proved to be positive, and the rise in antibody in those previously positive was greater with the CRA virus than with the Lee. Sera from several other sources which showed less than a fourfold rise in antibody to the Lee virus were then retested with the Lee and CRA strains. Of 103 pairs of sera so tested, 55 showed no rise in antibody with either strain, 25 a twofold rise with both, 17 a twofold rise with CRA only, and 6 a fourfold rise with CRA without any corresponding rise with the Lee. A further 53 pairs of positive sera were tested with both strains: 29 showed a fourfold rise with both, 14 a fourfold rise with Lee and eightfold or greater with CRA, and 10 a sixteenfold rise with Lee and only a fourfold rise with CRA.

TABLE V—FURTHER ANALYSIS OF FERRET SERA

Specific antigen	Specific ferret antiserum					
	LEE	CRA	Eliz B	Mil B	Paddington	P.R.8
LEE ..	2048	64	64	64	256	8
CRA ..	256	1024	256	256	256	16

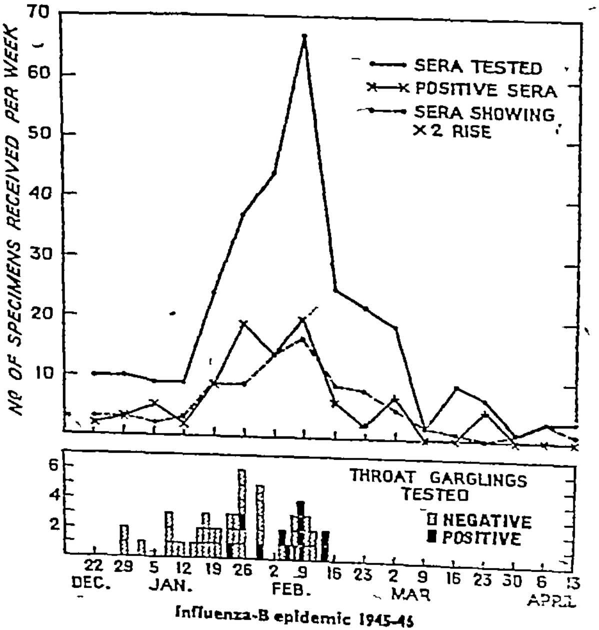
Paddington	1024	64	256	256	2048	16
P.R.8 ..	16	8	8	8	8	4096

A group of 24 persons was vaccinated with influenza-virus vaccine containing both A (P.R.8) and B (Lee) viruses through the coöperation of the medical superintendent, Darenth Park, Dartford, Kent. Serum samples were taken before and after vaccination and were tested for antibody rise by Hirst's method. The results showed an equal rise in B antibody to both Lee and CRA viruses. Such a result is encouraging, since it indicates that current vaccines, in which Lee virus is used, are likely to be as effective in protection against other strains of B as against the Lee virus.

INOCULATION OF FERRETS

Between November, 1945, and March, 1946, garglings from 45 patients and suspensions of lung from 2 fatal



Influenza-B epidemic 1945-46

Army in Europe were examined at the National Institute for Medical Research. Serum samples were received from all Service Commands, from public-health departments of the Allied Military Government, and from hospitals and practitioners throughout the United Kingdom. The figure shows the average weekly number of pairs of sera received and indicates the trend of the epidemic.

TABLE II—ANALYSIS OF SERUM SAMPLES RECEIVED AT M.R.C.

Pairs tested in the U.K. and B.A.O.R.	Virus A					Virus B				
	Negative		Positive			Negative		Positive		
	Rise in antibody					Rise in antibody				
351	0	×2	×4	×8	×16	0	×2	×4	×8	×16
	229	104	10	7	1	135	102	40	48	26
Total	333		18			237		114		

The method used in the agglutinin-inhibition tests was that described by Hirst (1942). The following standard conditions were observed.

Both specimens of serum were tested together on the same day with the same batch of antigen and with the same batch of fowl red cells (cf. Stuart-Harris 1943).

Reconstituted dried allantoic fluid, received from the Rockefeller Foundation in 1943 and containing A (P.R.8) and B (Lee) strains, was used as antigen.

Standard immune serum against A and B virus was tested with these antigens at regular intervals as a check on the results.

Fowl red cells were obtained from Plymouth Rocks and pooled before use.

A fourfold rise or greater was taken as a positive result.

The results of testing 351 pairs of sera are shown in table II. The serological tests clearly indicate that most infections were caused by the B virus, though some cases of A-virus infection were encountered. The most striking fact that emerges from these figures is the large number of sera that showed no rise or only a twofold rise in antibody. Many such cases occurred in closed communities, in hospitals and factories in which virus-B infection was known to be present; for example, in one London hospital, among 5 nurses whose sera were tested, 2 proved to be positive for B, 1 showed a twofold rise to B, and 2 were negative to A and B. We also encountered, as have other observers, cases from which virus B was recovered but yet no specific serological response to that virus developed during the disease. Reference is made below to tests against different serological strains of B.

In several instances sera showed a rise in both A and B antibodies. A small epidemic occurred at a tuberculosis convalescent centre in Middlesex (Grim's Dyke) in January; 3 of the cases showed a sharp rise of antibody: ×4 (A), ×8 (B); ×2 (A), ×4 (B); and ×4 (A) and ×8 (B). Several other such cases were encountered during the epidemic, but their explanation is obscure. Henle et al. (1946) have even encountered cases of experimental infection with virus A showing a serological response against B only.

Two instances of selective incidence were observed. At a R.A.F. station in Berkshire an epidemic occurred in late December and was entirely confined to the coloured West Indian population of the station, though both the coloured and white populations worked in close association. Serum analysis showed this to be a virus-B infection. A month later a further epidemic occurred among the West Indians, this time a virus-A infection. A case of virus-A infection was also identified among the white population. Further details are given in an accompanying paper (Jackson 1946).

About the same time a sudden small but sh epidemic was reported among coloured West Ind at another R.A.F. station in the Midlands. This prov to be due to the A virus and coincided with the seco wave at the other station.

VIRUS ISOLATION: ADAPTATION TO EGGS

Throat garglings from typical cases of influenza collected and inoculated into ferrets and develop chick embryos. Such specimens were collected as f as possible under standard conditions by the followi method.

The patient was asked to gargle 15 c.cm. of normal sali and to spit into a sterile bottle containing 5 c.cm. of hors serum broth. The specimen was kept cold, usually at −76° until used. The specimens from the Continent were collected and dispatched by air in a large 'Thermos' flask, unde the personal supervision of Lieut.-Colonel F. E. Buckland, R.A.M.C., of the medical directorate, B.A.O.R. The majority arrived at the National Institute in a satisfactory condition for examination. As far as possible, serum specimens f Hirst tests were obtained from all cases as a check on th presence of specific influenzal infection.

The method used for virus isolation was that describe by Beveridge and Burnet (1946). Garglings were not filtere but were inoculated directly into the amniotic cavity 13-day chick embryos in the presence of penicillin and sodium sulphadiazine. Each egg before inoculation received 0·1 c.cm of 5% sodium sulphadiazine. Sufficient penicillin to produc a final concentration of 125 units/c.cm. was mixed with th garglings before inoculation. These proved to be satisfactory bacteriostatic agents in most cases. Eggs were incubated at 37° C before and 35° C after inoculation. All inoculated embryos were incubated for a further 72 hours, after which all surviving eggs were placed in the ice-box for 2 hours before harvesting. The amniotic fluid from each egg was withdrawn into sterile tubes and tested with fowl and guineapig red cells for the presence of agglutination.

It was thought, in view of Burnet's work on the charac teristics of recently isolated A strains (Burnet and Bul 1943), that a new virus in its first amniotic passage (O-phase would agglutinate guineapig red cells to a higher titre than would fowl red cells. When later the current virus was isolated it was found to agglutinate the cells of both species to an equal titre, and the practice of using only fowl cells wa followed. Burnet *et al.* (1946) also found no evidence of a O-phase in the B strains they isolated.

All amniotic fluids were tested for sterility; those sterile after 24 hours were passed to a further group of six egg Each specimen was taken through three amniotic passes if negative at the end of this, passage was discontinued, but th gargling was retained at −76° C for further examination late

In all, 54 different garglings were tested, and viru was isolated in 12 cases. In 3 cases agglutination wa

TABLE III—ANALYSIS OF VIRUS ISOLATION IN CHICK EMBRY

No.	Date in 1946	Place	No. of amniotic passages			Subsequent allantoic inoc.	Rise in human antibody	Result of ferret inoc	
			1	2	3			Pyrexia	Ant bod
1	Jan.	*Bergkirchen	−	+++	+++	+++	×8 (+)	−	+
2	Jan.	London	−	++	+++	+++	×16 (+)	−	−
3	Jan.	Surrey	−	+++	+++	+++	×2 (−)	−	+

* B.A.O.R. NT, not tested.

ted on the second amniotic passage but was not present n the third; these were classed as negative (see ble III). The first 2 cases in which virus was isolated ccurred in January, one from a patient in Germany, ne other from a nurse in Surrey with a severe form of nfluenzal pneumonia. Specimens of amniotic fluid econd amniotic passage) were tested against specific and B ferret antisera. The virus was inhibited by (Lee) serum but not by A serum; the current virus as therefore a B virus.

Until the first isolation in January 18 garglings had een tested with negative results. After this, more uccessful results were obtained, and this increase in he number of cases in which virus was isolated coincided ith the increase in the recorded number of deaths from nfluenza. Though several of the earlier garglings were aken from patients who were later shown serologically o have had influenza, it was impossible to isolate the irus from these garglings, and repeated attempts to isolate he virus from material stored at —76° C failed. A possible xplanation is that the virus underwent some change uring human passage which made its isolation easier.

All strains isolated were readily adapted to growth in he allantoic sac. Using third amniotic passage material, ·1 c.cm. was inoculated into the allantoic cavity of 10-day hick embryos. The fluid was harvested after 48 hours nd its agglutinating titre tested by Hirst's method. The welve positive strains were regarded as distinct until hey had been compared antigenically one with another nd with other known strains. Owing to the number nvolved it was impossible to proceed with them all.

CLE ..	64	1024	1024	2048	2048

ANTIGENIC COMPARISON

An early attempt was made to compare the current trains with previously isolated B strains, the standard (Lee) strain and the Paddington strain. Two recent trains, Eliz B and Mil B from an epidemic in Melbourne 1945, were sent to England by air by the kindness of r. F. M. Burnet.

Specimens of allantoic fluid from each of the five trains—Lee, 4 current strains, Paddington, Eliz B, and il B—were inoculated into ferrets for the production of pecific ferret antiserum. Owing to the difficulty experinced in adapting the current strains to mouse lung ee below), the only attempt at antigenic comparison as by Hirst's test. Table IV shows the comparison etween the Lee and four of the current strains, CRA, EI, CLE, CLA. These four appeared to be distinct from ee but to be themselves closely related. There was no elation to the A virus. Table V shows a further analysis f several different B strains with their respective ferret ntisera. It can be seen that the Lee and the remainder, xcept possibly the Paddington, are distinct; there ppears to be a fairly close connexion between the CRA, liz B, and Mil B, though there are possibly some small ntigenic differences in the remainder of the subgroup. here is some tendency, also noted by Francis et al. 946) in the case of rabbit sera, for freshly isolated strains to be very susceptible to agglutinin inhibition heterologous and even normal sera.

In view of the differences between Lee and 1946 rains, human sera showing no antibody rise against Lee were retested against the CRA strain. For example, of 10 sera tested from a small epidemic at a school in Dorset, 5 were positive to B (Lee) and 5 negative to A and B. When these sera were retested with the current strain (CRA), 2 of the negative sera proved to be positive, and the rise in antibody in those previously positive was greater with the CRA virus than with the Lee. Sera from several other sources which showed less than a fourfold rise in antibody to the Lee virus were then retested with the Lee and CRA strains. Of 103 pairs of sera so tested, 55 showed no rise in antibody with either strain, 25 a twofold rise with both, 17 a twofold rise with CRA only, and 6 a fourfold rise with CRA without any corresponding rise with the Lee. A further 53 pairs of positive sera were tested with both strains: 29 showed a fourfold rise with both, 14 a fourfold rise with Lee and eightfold or greater with CRA, and 10 a sixteenfold rise with Lee and only a fourfold rise with CRA.

TABLE V—FURTHER ANALYSIS OF FERRET SERA

Specific antigen	Specific ferret antiserum					
	LEE	CRA	Eliz B	Mil B	Paddington	P.R.8
LEE ..	2048	64	64	64	256	8
CRA ..	256	1024	256	256	256	16
Eliz B ..	256	256 +	512	512	512	8

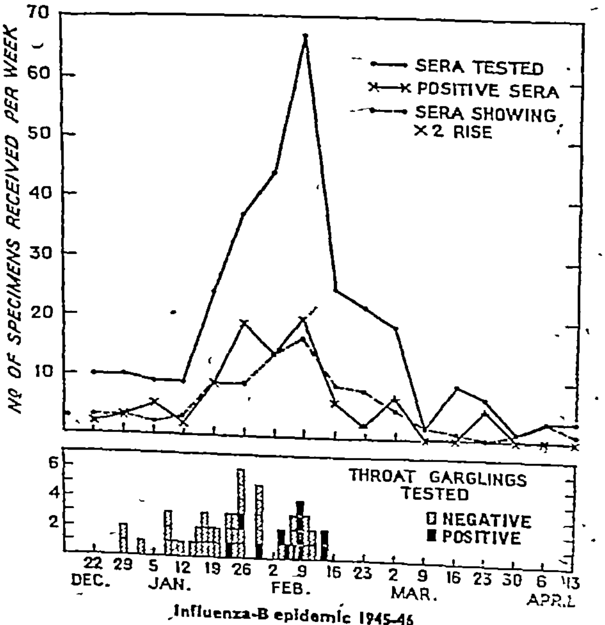
Paddington	1024	64	256	256	2048	16
P.R.8 ..	16	8	8	8	8	4096

A group of 24 persons was vaccinated with influenza-virus vaccine containing both A (P.R.8) and B (Lee) viruses through the coöperation of the medical superintendent, Darenth Park, Dartford, Kent. Serum samples were taken before and after vaccination and were tested for antibody rise by Hirst's method. The results showed an equal rise in B antibody to both Lee and CRA viruses. Such a result is encouraging, since it indicates that current vaccines, in which Lee virus is used, are likely to be as effective in protection against other strains of B as against the Lee virus.

INOCULATION OF FERRETS

Between November, 1945, and March, 1946, garglings from 45 patients and suspensions of lung from 2 fatal



Influenza-B epidemic 1945-46

8 2

cases of pneumonia were inoculated intranasally into anæsthetised ferrets. In most instances fresh material was used, but occasionally it had been stored for a short time at −76° C before being tested. No definite symptoms or pathological changes in upper respiratory tract or lungs were produced. Only 4 ferrets showed any fever, and from these no transmissible infectious agent was recovered. Even strains well established in eggs did not produce symptoms. With 2 strains serological evidence indicated that an inapparent infection was being passed in the ferrets, but four and five passages did not enhance the virulence of the strains for ferrets; this experience resembled that of Stuart-Harris et al. (1943). Serum samples were taken three or four weeks after infection from 27 ferrets inoculated with throat garglings; of these 4 were found to have developed antibodies to virus B, as shown by the Hirst test. Of 12 ferrets inoculated later with infected allantoic fluid all showed a rise in antibody to B virus.

ADAPTATION TO MICE

Attempts were made to adapt to mice 6 of the 1946 B viruses which had been isolated in chick embryos. These had received two amniotic and one or two allantoic passes and had developed good agglutinating power for fowl red cells before being inoculated intranasally, in the form of undiluted allantoic fluid, into mice. Of the 6 strains so tested, 4 produced extensive consolidation in the lungs of the first mice inoculated; this was as extensive in mice killed after four days as in those killed after eight days. No mice, however, died of the infection.

Previous experience with virus A led to the expectation that no difficulty would be encountered in transferring the infection serially, and in rapidly enhancing its virulence till it would kill the mice regularly; but, on the contrary, the extensive lung-consolidation seen in the first mice was never observed again. Much smaller lung lesions, involving an eighth or less of the lung, were seen in mice of some of the following passages, but there was no tendency for them to increase as transfer was carried on. That virus was still present was shown by transfer back to chick embryos, the fluids of which promptly acquired the specific red-cell-agglutinating properties of virus B. The small areas of pneumonia were detected to a varying degree up to 6, 6, 6, 7, 12, and 16 passages for the 6 strains. In the case of 3 strains virus was finally lost altogether, as judged by inability to infect eggs any longer. Passage of the other 3 was abandoned when it no longer seemed profitable.

Several modifications in technique were used in the hope of helping the adaptation to mice. Passage was carried out at intervals of two days, of three or four days (this was the usual practice), or of seven days. Virus survived for at least three passages at two-day and at least four passages at seven-day intervals, but no exaltation of virulence developed. Mixture with normal allantoic fluid was of no avail. Swiss mice were no better than our other (Parkes) strain of white mice. Mice from two to three weeks old were little if at all more sensitive than older ones. Cotton-rats proved no more susceptible than mice. One hamster inoculated with undiluted allantoic fluid died with complete lung-consolidation three days later, but attempts to produce a transmissible pneumonia in hamsters were not successful.

It seems possible that the lesions produced in the first mice inoculated were due to the "toxic" action of the large amount of virus present. Such an action has been produced in the rabbit's eye by Evans and Rickard (1945) and the mouse's brain by Hale and McKee (1945). The effects which these workers produced were not apparently associated with virus multiplication. Our findings recall strongly those recorded by Eaton et al. (1945) for their atypical pneumonia virus; this was transmitted as a symptomless infection in chick embryos, the fluids of which produced in cotton-rats and hamsters a pneumonia which was not serially transmissible.

VACCINATION OF HUMAN BEINGS

Trials were carried out of a polyvalent A and B vaccine (P.R.8 and Lee strains) made from fluids of infected chick embryos according to the method of Francis and Salk (1942). Several thousand doses were used on the Continent, and several thousand in this country. It is not proposed to report the results in detail now, because the incidence of clinical influenza was so low in nearly all the tested groups that no assessment of the value of the vaccine was possible. It may be said, however, that in the only two considerable groups with a high incidence the vaccine apparently had some beneficial effect. Thus among medical students at Glasgow 9 of 105 controls developed influenza (8·6%); most of these were proved serologically to be influenza B; only 2 of 115 vaccinated persons (1·7%) were affected. At Woolwich Arsenal 68 of 622 controls (10·9%) and 31 of 609 vaccinated (5·1%) developed influenza. Serological tests were not carried out here. Perhaps because of the low incidence and because most inoculations were not done until the outbreak was already under way, the benefit was less striking than that lately reported by Francis et al. (1946).

DISCUSSION

The influenza-B outbreak now reported is the first on record for Britain caused almost wholly by the B virus; it is further worth considering in relation to the recent behaviour of virus B in the rest of the world. According to Francis et al. (1946), influenza B was endemic in 1945 in the U.S.A., giving rise to localised outbreaks in every month of 1945 from March onwards but causing more widespread trouble in November and December. Other accounts emphasised its appearance in June, 1945, in the Pacific (in Hawaii and Guam) and its apparent spread southwards to Australia in November, 1945 (cf. Burnet et al. 1946), and eastwards to the Caribbean area, the northern part of South America, Texas, and further north in the U.S.A. Burnet's account of its clinical and epidemiological behaviour is an almost exact counterpart of our own experience—particularly its mildness and apparently capricious incidence with a tendency to attack younger age-groups. This, together with the similar biological behaviour and close serological relation we have found between the Australian and British strains, suggests that virus B may in fact have been travelling round the world. The view that such may happen is not necessarily in conflict with the concept that influenza viruses—A or B—may be endemic in many countries, awaiting suitable conditions to start an epidemic. Shope (1943) has convincingly presented the arguments for such a state of affairs as regards swine influenza. But the recent world-wide occurrence of influenza B suggests that a virus—perhaps as a result of the appearance of an antigenic variant in one of its endemic foci—may at times spread very widely, as pandemic influenza certainly did in 1918. The influenza B of 1945–46 was fortunately mild and the virus certainly not widely dissimilar from other B strains.

In this laboratory we have been hitherto unsuccessful in repeating the isolation of influenza-A viruses directly from human garglings into embryonated eggs—as described by Burnet (1935) in Australia and later confirmed in America (Hirst 1945). It remains uncertain whether our success with B viruses this year is due to the inherently greater ease of isolating B viruses, as contrasted with A, or to some other factor.

SUMMARY

Influenza, probably due to virus B, appeared in Holland and Belgium in December, 1945, but no widespread epidemic occurred in Ger

Britain a moderately extensive outbreak of a mild
of influenza began in January, reaching its peak
end of January.

ological evidence indicated that 34% of the cases
een December and March were due to influenza
B. We know that not all the cases of B-virus
ion show a specific serological response; so it is
that virus B was the major cause of the outbreak.
rrets did not show a febrile reaction when inoculated
1946 B viruses, but strains were successfully estab-
l by amniotic inoculation of fertile eggs. They
serologically rather distinct from the standard
B virus but very closely related to two strains
ted in Australia in November, 1945.

wish to thank for their help Brigadier J. S. K. Boyd,
or of pathology, War Office; Dr. G. E. Godber and
officers of the Ministry of Health; the numerous
rs, Service and civilian, who kindly provided sera or
ings for test; the professors of pathology and bacteriology
the medical officers of factories and other doctors who
orated in trials of vaccine; Dr. Robert Cruickshank,
al Public Health Laboratory, Colindale, for his assist-
in distributing the vaccine to those concerned in the
and our assistants, Sergeant W. A. Fitzgerald, R.A.M.C.,
E. Brodaty, and Mr. E. E. Owen, who gave valuable
ical assistance.

FLUENZA B AMONG WEST INDIANS

BREAKS IN THE BAHAMAS AND IN ENGLAND

W. P. U. JACKSON
M.B. Camb., M.R.C.P.
LIGHT-LIEUTENANT R.A.F.V.R.; FORMERLY MEDICAL
SPECIALIST IN THE BAHAMAS

E two outbreaks of influenza described here, one
ew Providence Island, Bahamas, and the other
ngland, were almost entirely restricted to coloured
The attack-rate was very high, and the type of
monic complication was unusually uniform. In
outbreaks evidence was obtained incriminating the
nza-B virus.

In the Bahamas

the summer of 1945 an epidemic of an upper respira-
disease, which was almost certainly influenza,
out on New Providence Island, Bahamas, British
Indies. No record of any previous epidemic of
nza in the Bahamas has been found, nor of any
ar "reverse colour-bar" having been exerted by
nfluenza virus. In the pandemic of 1918–19 it was
ved that non-Europeans of several races were more
and more severely attacked than Europeans
ch 1920), but never was the difference so great as
e present outbreak.

e epidemic is described here as it affected Service-
only. There was a concurrent outbreak of influenza
g the civilian native population, but details are not
able. British white personnel in the R.A.F. on
Providence numbered a little over 2000, divided
ly between two airfields eight miles apart. The coloured troops included some 370 men of the Bahamas Defence Corps (B.D.C.) and 280 men of the Bahamas Air Service Squadron (B.A.S.S.). The B.D.C. were billeted in the city of Nassau, and the B.A.S.S. on an airfield four miles away. These troops would, of course, mix in the town in the evenings. At the time of the outbreak there were also some 15 coloured patients in the R.A.F. hospital, at a third separate location, drawn from either contingent. Some B.A.S.S. men worked in the hospital, and, together with the patients' visitors, provided opportunity for dissemination of infection there. There were, then, three nuclei of coloured Servicemen—B.D.C., B.A.S.S., and hospital patients—and the outbreak attacked all three simultaneously (fig. 3). (The term "coloured" is used to include half-caste mulattoes who were serving in the Forces with the pure negroes and were attacked in a proportion at least equal to them.)

HISTORY OF OUTBREAK

The mode of entrance of the influenza virus to the island was not ascertained. The epidemic certainly involved other islands of the Bahamas group, but not the mainland of Florida, which is the nearest land to this archipelago, about sixty miles away from its tip.

Though a few cases of a febrile influenzal type of illness had been occurring in coloured Servicemen from the middle of June, the first real intimation of the epidemic was on the afternoon of June 24, when 6 men, already in the hospital for other complaints (4 in the V.D. ward), complained of malaise, feverishness, aching in the back, and headache, and all had temperatures above 101° F. Next morning 64 men appeared on sick parade with the same symptoms, which had mostly started the day before.

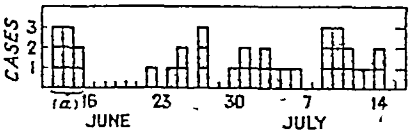

Fig. 1—Time distribution of 36 influenzal cases, admitted to hospital, among 2000 white troops in the Bahamas (attack-rate 1·5% for period *June 16–July 14*). Each square represents a case, and the date is that of the patient's first reporting to a doctor. *(a)* May 1–June 15.

Three Nissen huts were taken over for emergency hospital accommodation, one for B.A.S.S. men and two for B.D.C., in their respective camps. After this extremely explosive outbreak the case-incidence diminished daily. Fig. 1 shows that there was an increase of respiratory-tract and influenzal infection in the white troops at the same time, but this was very slight. The attack-rate for the month June 15–July 14 was 1·5% of this population at risk, while the corresponding rate for native troops was 34%. The total number of coloured men attacked and admitted to the wards was 219. Moreover, most of the upper respiratory-tract infection in the whites at this time was more coryzal than influenzal, and clinically more deserving of the name "febrile catarrh" (Stuart-Harris et al. 1938) than influenza.

This case-incidence of 34% is very high, particularly for an epidemic of the single-peak type. The attack-rate in a severe epidemic is usually about 10–20% (Stuart-Harris 1945, Van Rooyen and Rhodes 1940). Stuart-Harris saw an outbreak in a boys' school in 1937 reaching 50%, but virus was not recovered; Hare et al. (1943a) reported a case-incidence of over 30% of influenza-B infection in parts of Canada in 1943. Such figures are unusually high, except in establishments in which personnel is continually changing—e.g., Coleman (1944) noted that 40% were infected in an outbreak in a R.A.F. recruit camp, or 75–80% if ambulant cases were included. The Bahamians were not recruits, and neither contingent was subject to continuous change of personnel; in fact more changes took place among the white R.A.F. troops.

TABLE I—CONVALESCENT AGGLUTININ-INHIBITION TITRES

Patient	Influenza A	Influenza B	Result
1	128	512	? Positive B
2	64	128	? Positive B
3	64	512	? Positive B
4	8	128	? Positive B
5	32	1024	? Positive B
6	64	512	? Positive B
7	8	128	? Positive B
8	8	8	Negative
9	128	1024	? Positive B
10	32	512	? Positive B
11	8	256	? Positive B

In the Bahamas epidemic, only febrile patients admitted to hospital are included in the figures. Many more besides these were less severely affected, and it is almost certain that the full attack-rate of the coloured troops at risk was above 50%. Incidentally, of the British troops who did succumb a high proportion were medical staff who had been dealing with coloured influenza patients.

CLINICAL FEATURES

The clinical features of the cases were remarkably uniform and conformed almost exactly to those described in other proved influenzal epidemics—e.g., Stuart-Harris's (1945) description of influenza-A infection. The main point of difference from his description was the type of onset often encountered in this epidemic. Thus, in about 45% of cases it was insidious, with a premonitory phase including vague feelings of malaise for two or three days, with some frontal headache, perhaps a pain in the substernal region, and a little cough. There would then be an acute exacerbation, usually in the evening, with shivering, feverishness, increased malaise, and weakness, together with other usual influenzal symptoms and a rise of temperature to perhaps 102° F. Now, an insidious onset has been described by some authors (Hare et al. 1943b, Beveridge and Williams 1944) as more characteristic of infection by influenza-B virus. However, they also describe frequent premonitory coryzal symptoms, which were very rare here, though such symptoms developed during the course of the fever in 20% of the cases. In the influenza-B outbreak described by Nigg et al. (1942) exactly the same percentage of cases developing coryzal symptoms was noted.

The fever lasted 2–6 days, and was often biphasic. There was no mental depression or debility after the attack. Total white-cell counts and chest radiography in a few cases selected at random gave results within normal limits in all uncomplicated cases.

PNEUMONIA AS A COMPLICATION

The epidemic was complicated by pneumonia in 21 patients, all of whom came from the B.D.C. but were evenly distributed between the two emergency hospital huts in which they were housed. The proportion of pneumonia developing in all coloured patients was thus 9·6%, or in the B.D.C. contingent 13·8%. All cases started within the nine days July 1–9 (as shown in fig. 2), and there had been no pneumonia in the native troops in the previous two months. The time of onset of the pneumonia varied from 0 to 14 days after the patient's originally reporting sick with the symptoms of influenza, such intervals being similar to those described in other epidemics (French 1920, Scadding 1937, Lennette et al. 1941).

The type of pulmonary involvement was remarkably uniform and represented a fairly typical picture of rather mild localising pneumococcal lobar pneumo throughout, in sharp distinction to other previous recorded outbreaks of "influenzal pneumonia" (Leic tenstern 1912, Chickering and Park 1919, Stone an Swift 1919, French 1920, Scadding 1937, Maude 19 Lennette et al. 1941). In the present series there no necropsies, but radiographic evidence always [illegible] the physical signs.

The onset, in all but one patient, was abrupt, wit pleuritic pain and often a rigor. The temperatur exceeded 104° F in every case and remained high until it defervescence, which was usually by crisis. The physica signs suggested in each case a localised area of confluent consolidation. Sputum from every patient showed considerable numbers of gram-positive cocci in pairs in the direct smear and grew pneumococci on blood-agar, usually in pure culture. Pneumococci were also grown from the blood of one patient. In every patient but one, radiography showed localised unilateral changes in one zone of the lung fields, suggesting consolidation. In the one case it seemed likely that radiographic evidence was obscured by heart shadow. All cases except four responded to sulphadiazine within forty-eight hours. The fall of temperature was more delayed in three cases, and an empyema developed in the fourth.

SEROLOGICAL DATA

Single specimens of convalescent serum were obtained from 11 patients, in each case about fourteen days after the onset of the illness. The sera were analysed at the Army Medical School, Washington, D.C., and the results received from Colonel J. Smadel are shown in table I. The agglutinin-inhibition titres (Hirst test), in all but one case, were higher for influenza-B virus than for influenza-A virus, and afford presumptive evidence of influenza-B infection, especially where such titres as 1/1024 were recorded. Moreover, the one definitely negative serum, whose titre of 1/8 was so much lower (16 times) than the next lowest titre, makes it even more probable that the others had been recently infected with influenza-B virus.

PNEUMONIA IN RELATION TO TYPE OF INFLUENZA

Most previous reports of post-influenzal pneumonia were probably drawn from influenza-A outbreaks. Such pneumonia seems always to have

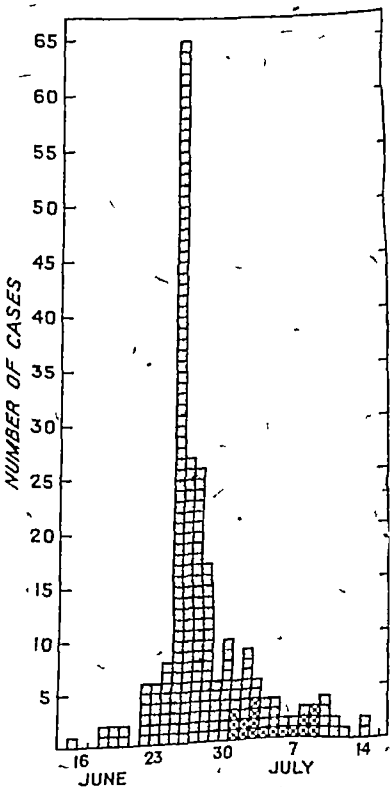

Fig. 2—Time distribution of 219 influenzal cases, admitted to hospital, among 650 coloured troops in the Bahamas (attack-rate 34%). The date is that of the patient's first reporting to a doctor. There were no cases in the period May 1–June 14. Each cross represents onset of pneumonia as a complication.

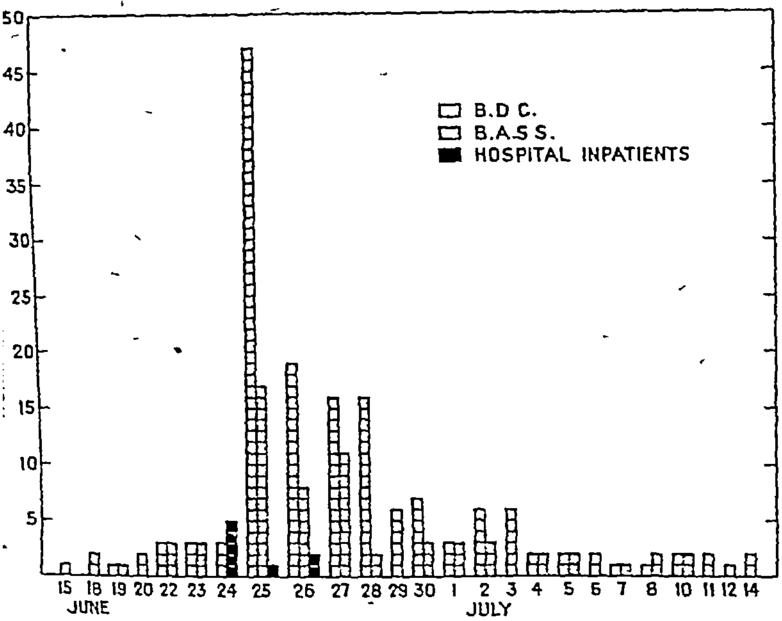

ig. 3—Time distribution of the same influenzal cases as in fig. 2, according to source, plus 8 hospital inpatients.

differed vastly from the true classical lobar type. Now, pneumonic involvement following influenza B is believed to be less common than after an influenza-A infection (Stuart-Harris 1945). Nigg et al. (1942) reported an influenza-B outbreak in 76 patients and staff of a mental hospital in Minnesota in 1942. Pathological changes were demonstrated by radiography of the chest in 8 patients, and 4 were said to have had lobar pneumonia. All these 4 patients died. Pneumococci were isolated from the sputum of all 8 patients. Otherwise little seems to have been published on influenza-B pneumonia since the discovery of the influenza-B virus by Francis (1940), though there have been reports from America of fourfold rises in B antibody serum titre in outbreaks of clinically non-influenzal true lobar pneumonia, without any concurrent influenza in the neighbourhood (*United States Army Medical Department Bulletin* 1945).

RELATION OF EPIDEMIC TO INFLUENZA ELSEWHERE

Since the middle of April, 1945, there had been small outbreaks of influenza in many parts of the world, and whenever a virus was incriminated it turned out to be the influenza-B virus. Places concerned included Colorado,* Texas* (June and July), Indiana,* S. Carolina, Virginia, California,* Washington, and Dakota * in the United States; the Hawaiians * (June), Guam,* Manila (May–July), Alaska,* Panama * (July), and S. America (July and August). It was even recorded in other islands of the West Indian group, in Jamaica (June) and Dominica (July and August). (*United States Army Medical Department Bulletin* 1945, *Epidemiological Information Bulletin of the* UNRRA *Health Division* 1945).

The Bahamas epidemic thus coincided chronologically with influenzal outbreaks in other parts of the world, and it is interesting that influenza-B virus was incriminated in many of them. All these outbreaks were in general similar in that they were sharply localised (in other places to a single camp or barracks, in the Bahamas to a single race) and showed an absence of postinfective asthenia, few severe complications, and few deaths.

In England

EPIDEMIOLOGY

On the four days Dec. 27–30, 1945, 10 coloured Jamaican Servicemen contracted a disease, clinically indistinguishable from influenza, on a R.A.F. station in Berkshire with a total strength of about 1000, of whom some 65 were Jamaicans. In and about the same period there was an undoubtedly increased morbidity-rate of upper respiratory-tract infection among the white troops; but, though some of this was influenzal in type, most resembled febrile catarrh or acute coryza. In figs. 4 and 5 only cases of influenzal or febrile catarrhal type occurring in the unit and necessitating admission for over forty-eight hours are included. This picture was an almost exact replica in miniature of the Bahamian epidemic.

The 10 Jamaicans who were infected worked in different sections on the same camp, the first 6 having their sleeping-quarters in the camp, whereas the other 4, taken ill on the 30th, all slept some four miles away. None of these patients were recent arrivals in the unit, and none had been on leave during the preceding week. During the same period there were several afebrile cases of upper respiratory-tract infection which may well have been influenzal, but these are not included; hence the attack-rate, among Jamaicans, of 15% in this small peak is a minimum.

Following this outbreak there were one or two scattered cases of influenzal illness, and then another peak in February, when in the five days Feb. 1–5 8 more Jamaicans were attacked. The two waves are shown in fig. 5. The outbreak then came to a close. The clinical attack-rate for Dec. 28–Feb. 14 was 32% of the coloured population at risk and 2·2% for the whites.

CLINICAL NOTES

First Wave.—Clinically the pictures were those of typical epidemic influenza. An insidious onset with primary coryzal symptoms, reported by some authors to characterise infection with influenza-B virus, was noted in 1 case only, though 2 patients had a previous chronic nasal catarrh, a very common complaint of West Indians in this country. The clinical picture was identical with that of the Bahamas epidemic, except that a true biphasic temperature chart was not observed and the mean duration of fever was a little less. One interesting point was that out of six differential blood films examined at the Radcliffe Infirmary, four showed atypical lymphocytes resembling Downey type 1 glandular-fever cells, and in three the mononuclear cells made up more than 50% of the total white cells (52%, 55%, 69%). On re-examina-

In the Bahamas epidemic, only febrile patients admitted to hospital are included in the figures. Many more besides these were less severely affected, and it is almost certain that the full attack-rate of the coloured troops at risk was above 50%. Incidentally, of the British troops who did succumb a high proportion were medical staff who had been dealing with coloured influenza patients.

CLINICAL FEATURES

The clinical features of the cases were remarkably uniform and conformed almost exactly to those described in other proved influenzal epidemics—e.g., Stuart-Harris's (1945) description of influenza-A infection. The main point of difference from his description was the type of onset often encountered in this epidemic. Thus, in about 45% of cases it was insidious, with a premonitory phase including vague feelings of malaise for two or three days, with some frontal headache, perhaps a pain in the substernal region, and a little cough. There would then be an acute exacerbation, usually in the evening, with shivering, feverishness, increased malaise, and weakness, together with other usual influenzal symptoms and a rise of temperature to perhaps 102° F. Now, an insidious onset has been described by some authors (Hare et al. 1943b, Beveridge and Williams 1944) as more characteristic of infection by influenza-B virus. However, they also describe frequent premonitory coryzal symptoms, which were very rare here, though such symptoms developed during the course of the fever in 20% of the cases. In the influenza-B outbreak described by Nigg et al. (1942) exactly the same percentage of cases developing coryzal symptoms was noted.

The fever lasted 2–6 days, and was often biphasic. There was no mental depression or debility after the attack. Total white-cell counts and chest radiography in a few cases selected at random gave results within normal limits in all uncomplicated cases.

PNEUMONIA AS A COMPLICATION

The epidemic was complicated by pneumonia in 21 patients, all of whom came from the B.D.C. but were evenly distributed between the two emergency hospital huts in which they were housed. The proportion of pneumonia developing in all coloured patients was thus 9·6%, or in the B.D.C. contingent 13·8%. All cases started within the nine days July 1–9 (as shown in fig. 2), and there had been no pneumonia in the native troops in the previous two months. The time of onset of the pneumonia varied from 0 to 14 days after the patient's originally reporting sick with the symptoms of influenza, such intervals being similar to those described in other epidemics (French 1920, Scadding 1937, Lennette et al. 1941).

The type of pulmonary involvement was remarkably uniform and represented a fairly typical picture of rather mild localising pneumococcal lobar pneum throughout, in sharp distinction to other prev recorded outbreaks of "influenzal pneumonia" (Le tenstern 1912, Chickering and Park 1919, Stone Swift 1919, French 1920, Scadding 1937, Maude 19 Lennette et al. 1941). In the present series there no necropsies, but radiographic evidence always supp the physical signs.

The onset, in all but one patient, was abrupt, pleuritic pain and often a rigor. The temperatu exceeded 104° F in every case and remained high until it defervescence, which was usually by crisis. The physica signs suggested in each case a localised area of confluen consolidation. Sputum from every patient showed considerable numbers of gram-positive cocci in pairs i the direct smear and grew pneumococci on blood-agar, usually in pure culture. Pneumococci were also grown from the blood of one patient. In every patient but one, radiography showed localised unilateral changes in one zone of the lung fields, suggesting consolidation. In the one case it seemed likely that radiographic evidence was obscured by heart shadow. All cases except four responded to sulphadiazine within forty-eight hours. The fall of temperature was more delayed in three cases, and an empyéma developed in the fourth.

SEROLOGICAL DATA

Single specimens of convalescent serum were obtained from 11 patients, in each case about fourteen days after the onset of the illness. The sera were analys at the Army Medical School, Washington, D.C., and t results received from Colonel J. Smadel are shown i table I. The agglutinin-inhibition titres (Hirst test, in all but one case, were higher for influenza-B virus than for influenza-A virus, and afford presumptive evidence of influenza-B infection, especially where such titres as 1/1024 were recorded. Moreover, the one definitely negative serum, whose titre of 1/8 was so much lower (16 times) than the next lowest titre, makes it even more probable that the others had been recently infected with influenza-B virus.

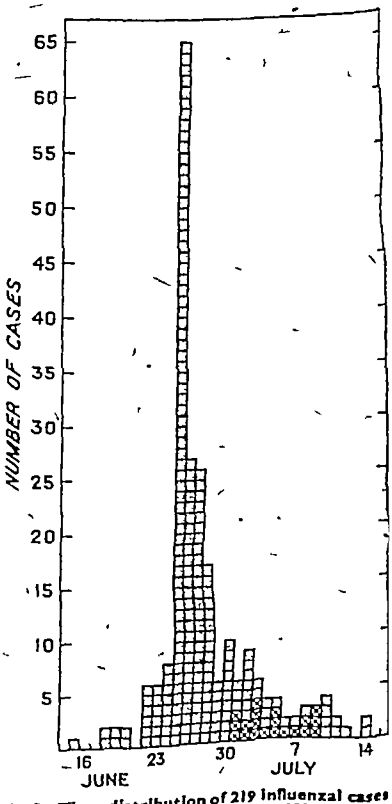

Fig. 2—Time distribution of 219 influenzal cases admitted to hospital, among 650 coloured troops in the Bahamas (attack-rate 34%). The date is that of the patient's first reporting to a doctor. There were no cases in the period May 1–June 14. Each cross represents onset of pneumonia as a complication.

PNEUMONIA IN RELATION TO TYPE OF INFLUENZA

Most previous reports of post-influenzal pneumonia were probably drawn from influenza-A outbreaks. Such pneumonia seems always to have and was recalled strikingly by the single case which occurred as a complication in the outbreak in England.

I am greatly indebted to Captain J. A. Dudgeon for analyses of the 1946 sera; to Colonel J. Smadel, of the Army Medical School, Washington, D.C., by whose courtesy Dr. J. Salk kindly obtained and forwarded the results of serum analyses performed in America; to Dr. R. L. Vollum for his help in obtaining serum samples; and to Squadron-Leader H. Halson and other station medical officers for permission to use their data.

ICTERUS GRAVIS NEONATORUM

END-RESULTS OF TREATMENT BY BLOOD-TRANSFUSION

HENRY THIRD
M.B. Aberd.

THE father of a baby with icterus gravis neonatorum asked me: "What do you promise me if you save the baby's life by blood-transfusion? A normal child? Or will it have something wrong with it?" This question prompted me to visit personally and review six babies whom I had successfully treated by blood-transfusion for this disease in 1944 and early 1945.

The average age of the babies is now eighteen months, and the accompanying table shows the genotype of the parents, the number of siblings in each family, and the end-result of survival by treatment with blood-transfusion. As most textbooks give only a short space to this grave disease of the newborn, perhaps it may serve some purpose to discuss the ætiology, diagnosis, and treatment in the light of recent research.

CASE 1.—The third child of the family, and the second to be affected, this baby had severe jaundice and showed signs of cerebral irritation due to affection of the nuclei of the brain by the jaundice (a true kernicterus). The Hb was never below 60% (Sahli), and there was no evidence of erythroblastæmia in the blood film. Four transfusions of 100 c.cm. of group-O Rh-negative blood were given. The end-result is an imbecile child.

CASE 2.—This baby was brought to hospital, thirteen days after birth, because of extreme anæmia, and was moribund. The blood-count was below 700,000, Hb 18% (Sahli), and erythroblasts and normoblasts comprised 20% of the field in the blood film. The baby was transfused once with 120 c.cm. of group-O Rh-negative blood and made a rapid recovery.

In this family the first five children were normal. After a severe miscarriage the mother was given a transfusion of an apparently homologous blood and had a most severe reaction (the blood was probably homologous within the ABO system only). The sixth child, born the following year, was extremely jaundiced and died of meningitis (kernicterus?) at four months; it was born jaundiced and remained jaundiced. The seventh child (case 2), the mother avers, was born "not yellow but pale, and grew paler." The child is now extremely healthy and robust.

CASE 3.—This was a second sibling, again showing erythroblastæmia, anæmia, &c. It was transfused three times with 100 c.cm. of group-O Rh-negative blood. It is now a normal healthy child.

CASES 4 and 5.—Twin girls with jaundice at birth and both showing erythroblastæmia, but the twin with the least evidence of erythroblastosis was the more deeply jaundiced and more gravely ill. They were each transfused with 120 c.cm. of group-O Rh-negative blood. The twin which showed the more toxic symptoms is undoubtedly by far the more backward. It is spastic and cannot walk or feed itself, whereas the other is apparently a normal healthy child.

CASE 6.—This is the third child of the family, and the first to be affected. It was extremely jaundiced (toxic) and showed no evidence of interference with the hæmopoietic system. It had retraction and fixation of the head and neck, and was extremely sensitive to touch and light. I am not yet prepared to say whether it is a normal child—I doubt it.

ÆTIOLOGY

There seems now to be no doubt but that icterus gravis neonatorum is caused by the iso-immunisation of the mother, by an antigen present in the fœtus (inherited from the father) which the mother lacks, and the subsequent passage of the antibody to this antigen into the fœtal circulation, where it exerts its noxious effect in different ways. Much has been written since 1944 about the rhesus antigens; the number of different antigens seems to increase monthly. There is also no doubt but that iso-immunisation of the mother takes place outside the rhesus system—indeed within the ABO system (McCall et al. 1944). Numerous instances have been reported during the past year.

DIAGNOSIS

A common feature of all cases of icterus gravis neonatorum is jaundice apparent at birth or appearing within a day or two of birth. The vernix caseosa may be very yellow. The typical and bizarre picture of some cases of erythroblastæmia is not always present and is not essential to the diagnosis. Investigation of the family will usually show that the first child escapes the disease, as iso-immunisation of the mother is unlikely in a first pregnancy. At the same time it has to be remembered that, in these days of multiple blood-transfusions for *divers diseases*, a mother may be immunised against rhesus by having had transfusions of blood homologous within the ABO system only—the rhesus factor having been ignored (Callender et al. 1945). This is undoubtedly happening. The final test in the diagnosis is the discovery of anti-rhesus or other abnormal antibody in the maternal serum; "finding anti-rhesus in the maternal serum makes the diagnosis almost certain" (Taylor and Race 1944a).

There seem to be, however, three very distinct pathological types, and these three types suggest that so far the subject is not completely investigated:

(1) *Hydrops fœtalis*, where the child is usually stillborn or dies within an hour or two of birth. It is generally œdematous, usually jaundiced, with skin inclined to peel, and has all the signs of a most severe toxæmia with large effusions into the serous cavities.

(2) The *toxic jaundice* type, where clinically there is evidence of a very severe jaundice and generally symptoms of cerebral or extrapyramidal irritation. The child may show definite signs of cerebral irritation, such as the typical cry, fixed position, retraction of the head, and extreme sensitivity to touch or light. Generally there is no erythroblastosis and the jaundice is not due to hæmolysis and is the true icterus gravis neonatorum.

(3) The third type is the *true erythroblastæmia*, where the jaundice is not so severe. The child is more pale than yellow, and the jaundice seems to be due to hæmolysis. The anæmia is more evident to the eye than is the jaundice. Here the blood picture is typical of a profound

TABLE II—RESULTS OF SERUM ANALYSES

tion some weeks later the abnormality was still present. The Paul-Bunnell test was negative in 5 of these cases tested once.

Later cases among the Jamaicans, including those of the second wave, were much more catarrhal and in ordinary circumstances would not clinically be considered influenzal at all. In this they were more like the cases among the whites, in whom a coryzal onset was the rule (in 67% of patients, against 36% of Jamaicans, in the whole outbreak). In general, too, the later cases had a lower and shorter fever.

Throughout the whole outbreak the onset was very variable; it might be abrupt or follow premonitory symptoms which had lasted as long as a week, catarrhal or general, highly febrile or afebrile.

There were second attacks in 4 Jamaicans, days between the two onsets being 13, 30, 35, and 50. The serum of 1 was positive for influenza-A virus in the second attack. In all 4 cases the second illness was more coryzal, without general aching in back and limbs.

In these few cases there was no clinical distinction between patients whose serum gave a negative result, was positive for influenza-A virus, or positive for influenza B, except that the first wave of influenza-B patients presented more general constitutional symptoms and fewer catarrhal symptoms than did the later mixed cases—the opposite of previously recorded differences between influenza-A and influenza-B infections (Hare et al. 1943a and b, Beveridge and Williams 1944).

SERUM EXAMINATIONS FOR INFLUENZA-VIRUS ANTIBODY

Specimens of serum in both acute and convalescent stages were taken from 5 patients in the first wave, and in all cases the virus-B antibody titre was at least quadrupled in the second specimen. This outbreak was therefore one of influenza B. Convalescent sera samples only were taken a little later from 5 white patients who had had a clinically similar illness, but these did not show a high titre of either A or B antibody. One of these white men had a second influenzal type of illness a week after his serum sample had been taken, and a later sample showed that his second illness had been influenza B.

The results from the second peak were less ... Serum from 2 Jamaicans demonstrated influenza-A in tion, and from 1 other was negative. A second attack 1 Jamaican produced no rise in A or B antibody, h first illness having been influenza B. Of the white me was shown to have had influenza A, and the serum i others was negative. One of the latter was an in when his illness started, and so he was the of close observation from his first premonitory sympto He had a fairly severe attack of absolutely characteris clinical influenza, much more typical than that of so other patients whose sera were positive for either A or B This second peak, therefore, was composed of a mixtu of influenza A, an influenzal type of illness with negativ serology, and perhaps influenza B also, as opposed to the first, apparently pure, influenza-B wave.

All sera were examined at the National Institute for Medical Research by Hirst's standard technique (Hirst 1942), and I am indebted to Captain J. A. Dudgeon for the analyses (table II).

COMPLICATIONS

A moderately severe follicular tonsillitis developed 1 case about eight days after the onset of influenza and two days after the patient had been discharged from sick-bay. A lobar pneumonia developed in 1 patient just a week after his influenza started, when he appeared almost fully recovered from this. His history and appearance were identical with those of the Bahamian pneumonia patients, except that his sputum remained extremely scanty throughout and was never bloodstained.

COMPARISON WITH OTHER R.A.F. STATIONS

The records of five other stations in the vicinity were examined, and the doctors in charge were interviewed. It was found that there had been, at four of these, similar influenzal outbreaks, virtually confined to West Indians. The peaks in all cases coincided with the two periods Dec. 23–Jan. 5 and Jan. 27–Feb. 16. Unfortunately no serological examinations had been made, and so these records are of clinical interest only. The only station without a Jamaican influenzal wave was the nearest of all to the camp considered above, at which virus was incriminated.

At another station, in the Midlands, there was a wave among Jamaicans between Jan. 22 and Jan. 31: 64 cases occurred in some 296 West Indians (22%), but only 13 in some 2600 white personnel (0·5%) (Halson 1946). Serological investigations were positive for influenza-A virus in 3 cases and negative in 3 others, comparable to the findings in the second wave in Berkshire. Clinically the picture was typical of influenza, without any preponderance of catarrhal symptoms. There were no complications.

SUMMARY

Two epidemics of influenza are described showing extraordinary similarities in that the epidemic peak were made up entirely of coloured British West Indian personnel, despite differences of season and of country. The reason for this previously unrecorded phenomenon is not known.

There is evidence that the Bahamian epidemic was one of influenza B, whereas the more recent epidemic in England was mixed but due to influenza-B virus at the start.

Epidemiologically the outbreaks differed in that the one in England consisted of two waves; but the total attack-rate (32%) over the whole period of the outbreak in England was very similar to that (34%) in the single peak in the Bahamas.

Evidence from other stations suggests that these phenomena were generalised in England in the winter 1945–46 and not isolated occurrences at one camp only.

The uniform lobar type of pneumococcal pneumonia complicating the Bahamian epidemic was very unusual

DETECTION OF AMINO-ACIDS IN URINE AND OTHER FLUIDS

C. E. DENT
M.R.C.P.
RESEARCH ASSISTANT, MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON

AMINO-ACIDS can be detected and identified in protein hydrolysates and other amino-acid mixtures by a method first used by Gordon et al. (1943) and further improved by Consden et al. (1944), who deal fully with the theory of their "partition chromatogram" and its application to amino-acid separations. It is only necessary to repeat here that the separation takes place owing to the different relative solubilities of each amino-acid between the water which is invariably held in the cellulose fibres of ordinary filter paper and a solvent, not miscible with water, which is allowed to creep slowly along the filter paper past a spot which contains the amino-acid mixture. The amino-acids are drawn along at definite speeds behind the moving solvent and thus arrange themselves in a characteristic order. After visible development by the ninhydrin reaction they can be provisionally identified.

In their original investigation Consden et al. (1944) took great care to avoid the presence of inorganic salts in the amino-acid mixture to be separated. They stated that "mixtures in which the ratio of soluble inorganic salts to amino-acids is high give unsatisfactory chromatograms." This, however, has not been my experience so far as concerns the inorganic salts constantly present in biological fluids, for their method has now been successfully applied to urine, protein-free blood filtrate, and other fluids, in which the ratio of inorganic salts to amino-acids may be anything up to 15 to 1. The method as now applied appears to constitute a valuable research and possibly diagnostic weapon.

TECHNIQUE

Full details as applied to pure amino-acid mixtures can be found in the paper by Consden et al. (1944). There are two versions of the process, the one-dimensional and the two-dimensional. The one-dimensional method uses a single strip 2 cm. wide and 45 cm. long of no. 1 Whatman filter paper and one solvent. It is easy to operate and, with liquefied phenol as the solvent, is used to detect pathological amounts of amino-acids. Fig. 1 shows the apparatus used here. In the case of urines, 25 c.mm. has been used as a routine. The urine is placed evenly from a small pipette right across the strip along a pencil line drawn about 6 cm. from the end which is to be dipped into the solvent, several applications being made, and left to dry, so that the urine is confined to as narrow an area as possible. The solvent is allowed to creep about 25 cm. past the urine line. This takes about sixteen hours. The strip is then removed, dried at 100° C, sprayed with 0·1% ninhydrin in butyl alcohol, and heated for ten minutes at 100° C. The amino-acids, if any, develop as purple bands. Normal urines vary in amino-nitrogen concentration from 10–30 mg. per 100 c.cm., as determined by formol titration (Van Slyke and Kirk 1933). They usually show two faint bands which have moved about 0·37 and 0·57 of the total distance that the solvent edge has travelled from the urine line. (This fraction is called the Rf value by Consden et al. (1944).) These bands are believed to be due one to glycine and the other to alanine. A further faint band is often seen at about 0·80. A urine with a total amino-nitrogen concentration of over 40 mg. per 100 c.cm. is easily distinguished. Fig. 2 shows developed strips from a normal urine and from a case showing progressive amino-aciduria, the Fanconi syndrome (see McCune et al. 1943). Fig. 3 shows the serial strips from a fatal case of subacute necrosis of the liver. Normal urines have been found in all cases of uncomplicated infectious hepatitis so far investigated. The colours of the ninhydrin reaction fade slowly and must be compared against standards at the time of development. For the photographs the urines were stored at 5° C over thymol and later tested and developed simultaneously.

The two-dimensional technique is more tedious but makes possible the identification of the amino-acids. Its use can be restricted to those fluids already sorted out as of potential interest by the strip method. The spot of liquid to be tested is placed near one corner of a large square of no. 1 Whatman filter paper (22 in. × 18 in.), and an adjacent entire edge of the paper is dipped into the first solvent. The cabinet required for this process will take two squares at a time and is described fully in the original paper (Consden et al. 1944). It must be emphasised that the cabinet should be kept at a constant temperature as far as possible during the development of a chromatogram. A small inside room has been found suitable here. The amino-acids are thus drawn out into a row of spots exactly as in the one-dimensional method. The paper is then dried and turned through a right angle, and the other adjacent edge is dipped into the second solvent. This moves the amino-acids in a direction at right angles; and, when the two solvents have very different properties, two amino-acids moved at the same speed by the first solvent may be separated by the second. All the amino-acids are thus separated from each other on the face of the paper and are developed visibly as before.

The two-dimensional method is also applicable to biological fluids. Fig. 4 is a diagram of the position of the amino-acids on the partition chromatogram made from 25 c.mm. of urine from a case of Fanconi syndrome. The amino-acids were identified by measuring their rates of movement in each solvent, the rates being characteristic for the amino-acids in question. A rough quantitative estimate of each amino-acid can be made by matching the size and intensity of the developed ninhydrin reaction with a known amount of the same pure amino-acid, run on the two-dimensional chromatogram and otherwise treated in exactly the same way as the unknown mixture. This procedure is necessary, as the strength of the colour reaction differs widely in an unpredictable way for equimolecular amounts of different amino-acids.

SPECIFICITY OF METHOD

The ninhydrin reaction as used above is practically specific for amino-acids and polypeptides. Some ammonium salts may give weak colours with ninhydrin (Cherbuliez and Herzenstein 1934), and where any of these are likely to be present they should be tried on the chromatogram to see how they move in the various solvents. The salts of the simpler organic acids (acetic, lactic) do not appear to interfere. Most other substances reported to react with ninhydrin (Copley 1941) are unlikely to occur in body fluids. The only serious confusion likely to

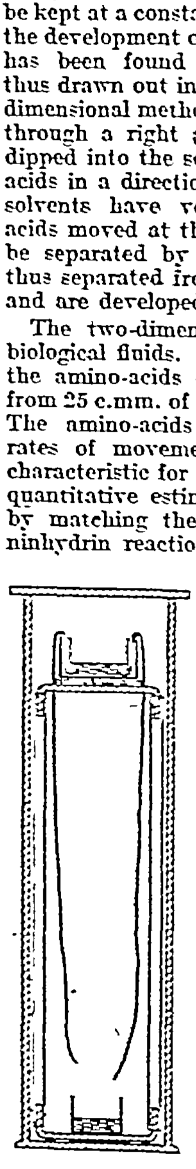

Fig. 1—Apparatus for one-dimensional chromatogram. It is contained in a glass specimen-jar 18 in. × 5 in. × 4½ in. fitted with a close-fitting glass lid. A staining trough 3½ in. × 2½ in. × 1½ in. contains the solvent (usually phenol) and stands on a glass plate on a support made of glass rod standing on legs of glass tubing. One end of the paper strip is dipped into the trough and held in position by a glass slide. The paper hanging down cannot adhere to the side of the trough, as the glass plate juts out a little way. A beaker below contains phenol and water to keep the atmosphere saturated and prevent evaporation from the strips. The apparatus will take six strips at a time.

ANALYSIS OF CASES OF ICTERUS GRAVIS NEONATORUM TREATED BY BLOOD-TRANSFUSION

Case	Parental blood-groups			Siblings	End-result
	Parent	Pheno-type	Geno-type		
1	F. M.	B, Rh +ve A, Rh −ve	B, R_1R_1 A_1rr	1st child normal 2nd child died of jaundice within a week 3rd child icterus gravis	Imbecile
2	F. M.	A, Rh +ve A, Rh −ve	$A_1R_1R_1$ A_1rr	1st to 5th children normal 6th child died of jaundice—kernicterus at 4th month 7th child erythroblastæmia neonatorum	Normal healthy child
3	F. M.	O, Rh +ve A, Rh −ve	O, R_1R_1 A_1rr	1st child well and healthy 2nd child erythroblastæmia neonatorum	Normal healthy child
4 & 5	F. M.	A, Rh +ve O, Rh +ve	$A_1R_1R_1$ O, R_1R_1	1st child stillborn (anencephalic) 2nd child, miscarriage at 3 months 3rd and 4th sibs twins, both showing erythroblastosis	One twin normal, the other spastic and backward
6	F. M.	A, Rh +ve B, Rh −ve	A_1Rr B, rr	1st child normal 2nd child slight jaundice 3rd child icterus gravis	Suspected of spasticity and backwardness

All mothers except 4 and 5 (twins) had anti-rhesus antibody in varying amount in their sera. In 4 and 5 it was suggested (1944) that "some irregular agglutinin of the St type may be the culprit." One would also point to the high percentage of the homozygote father, there being one heterozygote father in this series.

F. = father ; M. = mother.

disturbance of the hæmopoietic system, which seems to have taken the full brunt of the toxin. The film shows a high percentage of nucleated and immature red cells; early and late erythroblasts and normoblasts form a high percentage of the cells; and there are usually macrocytosis and polychromasia. The red-cell count is low; so also is the Hb percentage. It is undesirable to include all groups under either icterus gravis or hæmolytic disease, because not all cases are hæmolytic, nor are all cases severely jaundiced.

On the preventive side little or nothing so far has been done to prevent the occurrence of these catastrophes in the affected newborn. If, in the future, "a polysaccharide responsible for the specificity of the rhesus antigen can be isolated, its injection into the mother may neutralise the antibody and prevent or diminish its harmful effects on the fœtus" (Taylor and Race 1944a). Or is the answer to prevention to come on the day when an individual will be better known by his blood type than by his fingerprints, and marriages considered in terms of compatibility of blood genotypes rather than of temperament ?

TREATMENT

So far as present knowledge is concerned, the only treatment offering survival of the affected child is transfusion with group-O rhesus-negative blood until such time as the exact nature of the offending antibody has been ascertained, which can only be done in a laboratory fully acquainted with the complex subject. Whitby (1942) has written that "the homologous blood-transfusion is the ideal tissue graft," but one has to be certain that it is homologous. "The genes for the various blood groups and secretion appear to be in different chromosomes and so provide linkage markers for five (excluding sex) of the 24 pairs of chromosomes, whilst the characters themselves permit the division into a very large number of types thus: ABO × MN × Rh × P × secretion is 6 × 3 × 11 × 2 × 2, equalling 792 types" (Taylor and Race 1944b). Though all types are not important in deciding the appropriate blood required, it is becom increasingly evident that the exact nature of the offend antibody has to be investigated.

So far I have used group-O rhesus-negative blood t such time as I have had an exact report, the amount blood being 10–20 c.cm. per lb. of body-weight, vary according to the blood requirements. The affected ba is also artificially fed, as the antibody may be secreted the mother's milk. This treatment is also recommend where hæmolytic disease is due to iso-immunisation b an antigen other than rhesus.

Finally, to revert to the question of what can be offer to the parents of the affected child. It seems to me th only the cases of true erythroblastæmia are amenable t treatment by blood-transfusion, and here it must b remembered that transfusion per se is not a cure f erythroblastæmia. "It does not prevent the hæmoly of the child's own cells, it merely provides cells that w not be destroyed more rapidly than normal, and on whic the child can live until the lytic process ends" (Tayl and Race 1944a).

And what are we to do with the child that clinicall appears to be a definite candidate for the dread ker icterus, and destined to be affected one way or anothe from backwardness and spasticity to imbecility ?

SUMMARY

The end-results of treatment by blood-transfusion o six infants suffering from icterus gravis neonatorum a given. It is suggested that the offending antigens a antibodies are still imperfectly understood, and mor research is required.

It seems that the results are satisfactory in tru erythroblastæmia only. In the "toxic jaundice" typ there is grave risk that if the child recovers it will b faulty to the point of imbecility.

A fresh nomenclature and a more detailed patholog seem desirable.

ADDENDUM

Since this article was written Coombs et al. (194 have described a test for the detection of the in-vi sensitisation by maternal Rh antibody of the red cel of infants with hæmolytic disease, and have found thereb an antigen and its antibody of a type previou unknown. Their case 15, where the child died of jaund without anæmia and where the direct test was negati seems to confirm that the true pathology of the disea or diseases has not yet been elucidated.

The blood examinations in all my cases were perform by the Galton Serum Laboratory Unit at Cambridge, a I am indebted to the late Dr. G. L. Taylor, of th laboratory, who initiated me into the intricacies of t rhesus factor and supplied me with literature on the subje and to Dr. R. R. Race who has carried on this help.

AFTER a lapse of six years, publication has been resum of the Paris journal, *Annales de Médecine*. It was publish regularly every month during the war of 1914–18 but t German occupation in 1940 was too much for it. The edito say that they preferred silence to servitude under an arbitra and oppressive censorship. They are publishing four issu this year and hope to begin regular monthly publication ne year.

Another journal to come to life again after six years of w is *Rivista di Medicina Aeronautica*, published in Rome. Th present issue, for January–June, 1946, carries a suppleme containing a list (with titles also in English, French, an Spanish) of papers on aviation medicine published in Italy i 1940–46.

stine and methionine, have been found to excrete a rge excess of amino-acids in the urine. Even if only) c.mm. is available from the bladder post-mortem, this ample for both the one- and two-dimensional techiques to be applied. Bile pigments do not appear to terfere.

Many other applications to diseases of metabolic origin an be surmised. An opportunity to test the urine from case of acute yellow atrophy has not arisen.

SUMMARY

A simple method is described for detecting an excess f amino-acids in various body fluids. The aminocids can be identified with certainty by an elaboration f the method, which also allows of a rough quantitative stimate.

I thank Prof. A. C. Chibnall and his department for valuable dvice, and Prof. H. P. Himsworth and Dr. D. Hunter for roviding rare pathological material.

LEUCOTOMY TECHNIQUE

D. G. DUFF
M.C., M.B. Edin., F.R.C.S.E.
URGEON-SUPERINTENDENT, BELFORD HOSPITAL, FORT WILLIAM;
LATELY CONSULTING SURGEON TO NORTH WALES
COUNTIES MENTAL HOSPITAL, DENBIGH

THOSE with much experience of frontal leucotomy ill agree that, in well-chosen cases, the results, so far s we can see, can be remarkably good, if not easily xplicable. Hopeless and miserable misfits of social life, who for years have resisted all other methods, may be nade happy and useful members of the community.

Leucotomy is without doubt often performed with esitancy and inadequacy, and without very definite nowledge of the exact plane of section or the amount f white matter cut (Meyer and Beck 1945). The immeiate risk of the operation is hæmorrhage due to blindly utting across cerebral vessels which vary in position. Examination of frontal lobe sections (fig. 1) will show he wide variation in grey-matter conformation, not only etween different individuals and sexes but also between he two hemispheres of the same person.

In 1942, using the Moniz method of trephining on either ide of the bregma, I found that a curved probe-pointed istoury could section the frontal white matter very thoroughly, but there was a risk of severing branches of the anterior cerebral artery in the longitudinal fissure as well as vessels deep in the sulci on the exterior of the erebrum.

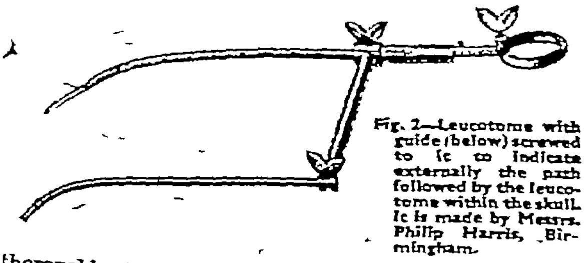

Fig. 2—Leucotome with guide (below) screwed to it to indicate externally the path followed by the leucotome within the skull. It is made by Messrs. Philip Harris, Birmingham.

Later, a sabre-shaped leucotome was given blunt dges which would not cut vessels, though they went easily through brain tissue. It was made as a cannula to give information should the lateral ventricle be punctured, for the optimal plane of section is agreed to be just in front of the anterior horn. A loop of snare wire was made to project from the cannula end (fig. 2). This was meant to cut closely under, or even into, the grey matter where the risk of cutting vessels was greatest. The wire is just sufficiently resilient to be deflected on meeting the tougher resistance of vessels big enough to bleed, but to resume its cutting once the obstruction is overcome. A centimetre scale was marked on this "cannula-leucotome." Satisfactory results were obtained, and over 30 cases have since been done without the least fear of intracranial hæmorrhage.

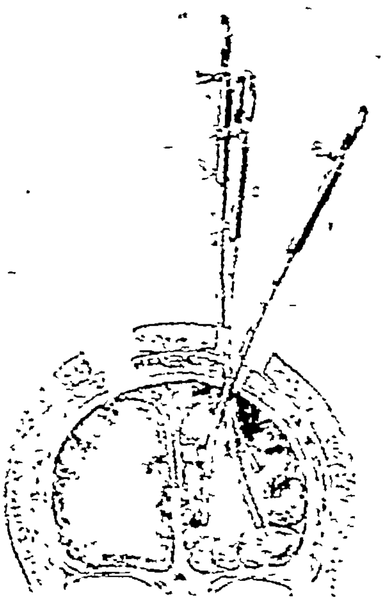

Fig. 1—Coronal section of frontal lobes, showing wide variations in cerebral anatomy of two hemispheres (drawn from different brains) and method of using leucotome: (1), (2), and (3) indicate successive positions of leucotome cutting at the site of election. (1) Leucotome approaching the falx cerebri in the longitudinal fissure; (2) leucotome swept outwards; (3) leucotome withdrawn upwards. Some brain sections show even more intrusion of grey matter and blood-vessels than that illustrated on the left side. (For clarity the guide is omitted.)

Local anæsthesia has as a rule been used, and with suitable premedication the patients are usually coöperative and unworried about the operation. Trephining has often a soporific effect.

TECHNIQUE

Some landmarks are marked on the shaven head with gentian violet—viz., the glabella; the midline point 13 cm. behind this (Freeman and Watts 1942), which is often the bregma; the orbital process of the frontal bone; a point a third of the way back from the nasion to the external auditory meatus (a calliper is used); and the upper margin of the zygomatic arch. To determine the mid-point of the vertex is not always easy, for even control measurements from the zygomatic arch on each side may be inaccurate owing to skull asymmetry. (A suitably nicked wire hoop is used.)

A bradawl is pushed through the anæsthetised scalp 3 cm. on either side of the bregma, and the skull thus pitted for the subsequent reception of the central pin of the ½-in. trephine or burr. An incision 3·5 cm. long is now made sagitally through the puncture mark, the pericranium stripped back, and the self-retaining retractor inserted. The trephine is operated with a brace; and, when the bone button is removed, a puncture place near the centre of the exposed dura is chosen which will provoke the least meningeal hæmorrhage—for this could prove more time-consuming than all the rest of the operation.

With snare wire fully retracted into the leucotome, this is pushed down through the frontal lobe till it touches the orbital plate of the frontal bone. It is kept just anterior to the plane a third of the way back from the nasion to the external auditory meatus, for this is ordinarily just in front of the anterior horn of the ventricle, which may reach forward to a plane half-way arise is in the case of simple di- and tri-peptides. This is a possible source of error in the identification of an amino-acid, and it should be suspected when a spot is found in an unusual position. The permanence of a spot after hydrolysis to break up the polypeptides would then have to be investigated.

Consden et al. (1944) have dealt fully with the question of the constancy of the position of the spots when pure amino-acid mixtures or protein hydrolysates are separated on the chromatogram. It only remains to illustrate how this has been confirmed for the amino-acids already identified in urines. Five separate two-dimensional chromatograms on three different urines from the same patient gave Rf values in phenol differing by not more than 5% for the amino-acids glycine, alanine, serine, threonine, and tyrosine and for a few other spots due to amino-acids not yet finally identified. The Rf values in collidine were more variable, up to 25%, but this could be largely related to the temperature at which the chromatogram was run, faster speeds being consistently obtained with lower temperatures and vice versa. The positions of the bands on the one-dimensional chromatogram were also constant among themselves, but by following the technique described here the Rf values were not closely comparable with those on the two-dimensional method. For instance the Rf value in phenol for glycine averages 0·37 on the former and 0·42 on the latter, a difference of 12%.

As an illustration of the method of identification of amino-acids, a urine from a case of Fanconi syndrome can be mentioned. This urine gave always four strong spots on the two-dimensional chromatogram roughly appearing in the positions expected for glycine, alanine, serine, and threonine. By trial and error it was found that a synthetic mixture containing 8 µg., 6 µg., 3 µg., and 5 µg. respectively of these acids closely matched in size and strength the spots obtained from 25 c.mm. of the urine. This, therefore, also gave a rough estimate of the concentrations of the amino-acids in the urine. The corresponding Rf values are given below:

		Phenol	Collidine
Glycine	in urine	0·43	0·22
Alanine	,, ,,	0·62	0·26
Serine	,, ,,	0·34	0·27
Threonine	,, ,,	0·53	0·30
Glycine	in synthetic mixture	0·42	0·22
Alanine	,, ,,	0·62	0·25
Serine	,, ,,	0·35	0·25
Threonine	,, ,,	0·50	0·30

These figures leave little doubt about the identity of the amino-acids in the urine, nor could the other urinary constituents have interfered in any way with the development of the chromatogram. However, it must be emphasised that, in view of the temperature effect and other variables, the synthetic mixture must always be run simultaneously in the same cabinet with the unknown. Some of the Rf values in the table above do not agree closely with those quoted by Consden et al. (1944).

Many other ways of confirming the identity of a doubtful spot could be tried—e.g., the addition of known "marker" amino-acids to the urine, and the removal of a spot from the chromatogram after specific precipitation of the amino-acid from the urine or after its destruction by a specific enzyme.

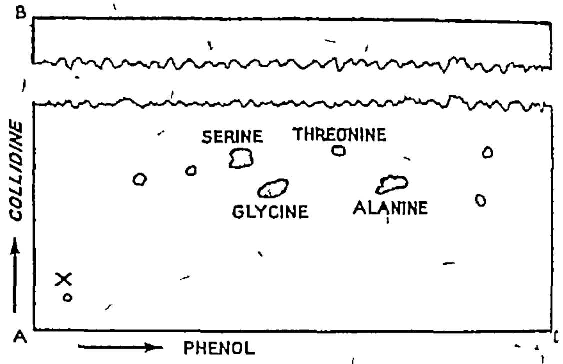

Fig. 4—Diagram of a developed two-dimensional chromatogram fr the urine of a fatal case of Fanconi syndrome complicated by carcinoma of the liver with widespread secondaries. The urine wa placed on the circle (x) at the left-hand corner. The edge AB wa dipped in phenol and the test run for 46 hr. After drying, the edge AC was dipped in collidine and run for 53 hr. The four strongest spots have been identified as shown. The remaining weaker spots are not yet identified. The amino-nitrogen concentration in the urine was 38 mg. per 100 c.cm.

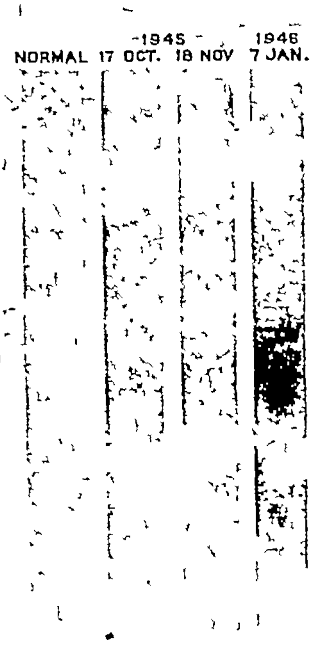
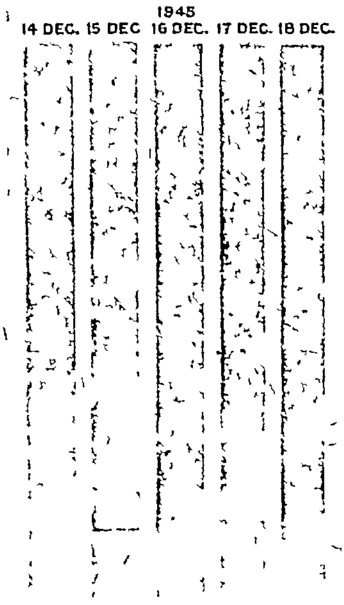


2



3

Fig. 2—Developed strips showing the amino-acids in the form of bands. The upper line shows where the urine was placed, the lower line marks the limit of phenol movement. The first strip is typical of a normal urine (amino-nitrogen concentration 13 mg. per 100 c.cm.). The next three strips are from a patient with progressive amino-aciduria (Fanconi syndrome) and were passed on the dates shown (amino-nitrogen concentration 46, 44, and 112 mg. per 100 c.cm, total 24-hr. output of amino-nitrogen 740, 910, and 1480 mg.).

Fig. 3—Developed strips from a case of subacute necrosis of the liver admitted with severe jaundice and ascites on Nov. 30, 1945. The urine then gave a normal chromatogram. On Dec. 6 the amino-acids were stronger but still judged within the normal range. The urines of last few days all containing a pathological excess of amino-acids are shown above. The patient died on Dec. 19 in coma. No tyrosine or leucine crystals were seen on microscopical examination of the urines.

OTHER USEFUL APPLICATIONS

The strip method has been used to dete casein hydrolysate in the diarrhœa stool of patient receiving oral therapy at Belsen. was estimated that a large proportion passing through the gut unabsorbed.

Study of cystinuric urine (from a case Mr. F. J. F. Barrington's) suggests that th strip method would be of diagnostic value this condition.

Serum and ascitic fluid can be run on th two-dimensional chromatogram, provided tha the proteins are precipitated by ten times th volume of alcohol, followed by final concen tration on the water-bath to an amino-nitroge content of about 50 mg. per 100 c.cm. Th involves a concentration to about a tenth the original volume of serum or ascitic fluid.

The method is particularly suitable experimental work. Rats with acute necros of the liver, brought on by a diet low ystine and methionine, have been found to excrete a rge excess of amino-acids in the urine. Even if only 0 c.mm. is available from the bladder post-mortem, this s ample for both the one- and two-dimensional techniques to be applied. Bile pigments do not appear to nterfere.

Many other applications to diseases of metabolic origin an be surmised. An opportunity to test the urine from a case of acute yellow atrophy has not arisen.

SUMMARY

A simple method is described for detecting an excess of amino-acids in various body fluids. The amino-acids can be identified with certainty by an elaboration of the method, which also allows of a rough quantitative estimate.

I thank Prof. A. C. Chibnall and his department for valuable advice, and Prof. H. P. Himsworth and Dr. D. Hunter for providing rare pathological material.

LEUCOTOMY TECHNIQUE

D. G. Duff
M.C., M.B. Edin., F.R.C.S.E.
SURGEON-SUPERINTENDENT, BELFORD HOSPITAL, FORT WILLIAM;
LATELY CONSULTING SURGEON TO NORTH WALES
COUNTIES MENTAL HOSPITAL, DENBIGH

THOSE with much experience of frontal leucotomy will agree that, in well-chosen cases, the results, so far as we can see, can be remarkably good, if not easily explicable. Hopeless and miserable misfits of social life, who for years have resisted all other methods, may be made happy and useful members of the community.

Leucotomy is without doubt often performed with hesitancy and inadequacy, and without very definite knowledge of the exact plane of section or the amount of white matter cut (Meyer and Beck 1945). The immediate risk of the operation is hæmorrhage due to blindly cutting across cerebral vessels which vary in position. Examination of frontal lobe sections (fig. 1) will show the wide variation in grey-matter conformation, not only between different individuals and sexes but also between the two hemispheres of the same person.

In 1942, using the Moniz method of trephining on either side of the bregma, I found that a curved probe-pointed bistoury could section the frontal white matter very thoroughly, but there was a risk of severing branches of the anterior cerebral artery in the longitudinal fissure as well as vessels deep in the sulci on the exterior of the cerebrum.

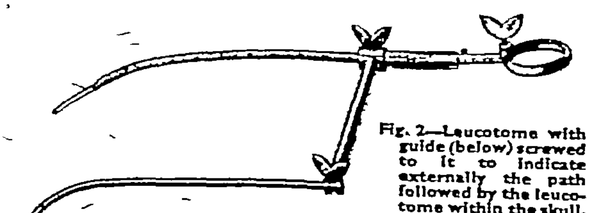

Fig. 2—Leucotome with guide (below) screwed to it to indicate externally the path followed by the leucotome within the skull. It is made by Messrs. Philip Harris, Birmingham.

Later, a sabre-shaped leucotome was given blunt edges which would not cut vessels, though they went easily through brain tissue. It was made as a cannula to give information should the lateral ventricle be punctured, for the optimal plane of section is agreed to be just in front of the anterior horn. A loop of snare wire was made to project from the cannula end (fig. 2). This was meant to cut closely under, or even into, the grey matter where the risk of cutting vessels was greatest. The wire is just sufficiently resilient to be deflected on meeting the tougher resistance of vessels big enough to bleed, but to resume its cutting once the obstruction is overcome. A centimetre scale was marked on this "cannula-leucotome." Satisfactory results were obtained, and over 30 cases have since been done without the least fear of intracranial hæmorrhage.

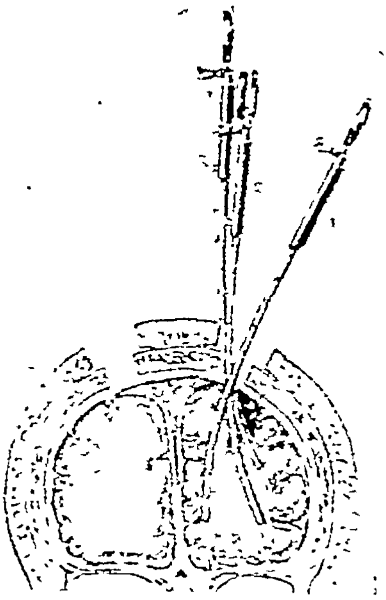

Fig. 1—Coronal section of frontal lobes, showing wide variations in cerebral anatomy of two hemispheres (drawn from different brains) and method of using leucotome: (1), (2), and (3) indicate successive positions of leucotome cutting at the site of election. (1) Leucotome approaching the falx cerebri in the longitudinal fissure; (2) leucotome swept outwards; (3) leucotome withdrawn upwards. Some brain sections show even more intrusion of grey matter and blood-vessels than that illustrated on the left side. (For clarity the guide is omitted.)

Local anæsthesia has as a rule been used, and with suitable premedication the patients are usually coöperative and unworried about the operation. Trephining has often a soporific effect.

TECHNIQUE

Some landmarks are marked on the shaven head with gentian violet—viz., the glabella; the midline point 13 cm. behind this (Freeman and Watts 1942), which is often the bregma; the orbital process of the frontal bone; a point a third of the way back from the nasion to the external auditory meatus (a calliper is used); and the upper margin of the zygomatic arch. To determine the mid-point of the vertex is not always easy, for even control measurements from the zygomatic arch on each side may be inaccurate owing to skull asymmetry. (A suitably nicked wire hoop is used.)

A bradawl is pushed through the anæsthetised scalp 3 cm. on either side of the bregma, and the skull thus pitted for the subsequent reception of the central pin of the $^1/_2$-in. trephine or burr. An incision 3·5 cm. long is now made sagitally through the puncture mark, the pericranium stripped back, and the self-retaining retractor inserted. The trephine is operated with a brace; and, when the bone button is removed, a puncture place near the centre of the exposed dura is chosen which will provoke the least meningeal hæmorrhage—for this could prove more time-consuming than all the rest of the operation.

With snare wire fully retracted into the leucotome, this is pushed down through the frontal lobe till it touches the orbital plate of the frontal bone. It is kept just anterior to the plane a third of the way back from the nasion to the external auditory meatus, for this is ordinarily just in front of the anterior horn of the ventricle, which may reach forward to a plane half-way between the nasion and the anterior clinoid processes. Should the anterior horn be punctured, fluid welling up will give the indication for reinsertion a little further forward.

The depth at which the orbital plate is reached is noted—e.g., 7–10 cm. (The bone is arched upwards.) The leucotome is withdrawn for a distance of 2 cm., and the snare wire is pushed down to project 1 cm. The leucotome is moved inwards towards the middle line, till it is judged close to the falx in the longitudinal fissure (^{1} in fig. 1). Resistance to its blunt edge is felt which will not let it go further, and the movement is done with confidence that branches of the anterior cerebral artery, even in abnormally deep sulci, will be pushed ahead and not severed.

The leucotome is now swept outwards (^{2} in fig. 1), the wire loop passing close to, or even cutting into, the thin, usually uniform layer of grey matter; the patient sometimes winces slightly as a sensitive area is touched. Occasionally sulci with contained vessels are present here, and resistance to the point is felt; the leucotome can then be withdrawn a little as required. When it is judged that the point is under the grey matter of the external surface of the brain, the instrument is gradually withdrawn upwards (^{3} in fig. 1), the snare wire being kept close under the brain surface, with the expectation that, should vessels in deeper sulci be encountered, the loop will be deflected and will not damage them.

The leucotome is removed, resterilised, and reinserted on the other side, where a similar operation is performed.

Some such technique is required to allow for the great variations in cerebral structure: differences in the extent to which grey matter intrudes on white, the depth of the sulci, the position and size of vessels, and the projection of the ventricular horn. It is expected in this way to make leucotomy (provided always that aseptic technique is faultless) no more dangerous to the patient than ordinary minor cerebral diagnostic procedures, possibly as little noxious as electric-shock therapy.

RESULTS

Detailed results of cases done with this technique will come more reasonably from the psychiatrists responsible for the patients. Only cases adjudged otherwise hopeless, of long duration, and resistant to all other treatments were treated by leucotomy. In some cases full recovery was not looked for; we hoped only for removal of suicidal, homicidal, or otherwise dangerous, destructive, or asocial habits, so that the patients should be made manageable and useful in the institution.

With this technique no death can be attributed to the operation nor has any patient been made worse. Of my 27 patients operated on since developing this technique, 4 showed practically no change, 7 are improved but still inpatients, and 15 were recovered sufficiently to resume life, and sometimes new and more responsible work, outside.

One died six weeks after operation with signs of congestion of the lung and pulmonary collapse. Necropsy showed that the white fibres of the brain had been adequately sectioned. There was no hæmorrhage, though the cut extended below to $^1/_2$ in. from the inferior aspect of the brain. In this case the superior frontal sulci penetrated $1^1/_4$ in. into the cerebrum, sulci on the medial aspect $^1/_2$ in., and those on the external aspect $^3/_4$ in., with the result that the white matter showed very irregular projections and vessels would be easily cut by a different leucotome.

Patients with signs of postencephalitic parkinsonism not only made good psychological recoveries after years of psychosis but also showed physical improvement. One with distressing symptoms of parkinsonism, chiefly unilateral, had a contralateral hemileucotomy with most satisfactory results (Schwarz 1945).

A further point must be emphasised about an operation so comparatively easy and occasionally so dramatic in its results, for it is a thrill (on occasion) to see the lines of anxiety disappear and the patient suddenly become extravert and interested for the first time in his surroundings just as the second hemisphere is cut. The decision to operate must not be influenced by the enthusiasm of the surgeon and the impatience of the relatives but must be strictly controlled by the mature experience of the institutional psychiatrist.

The work here outlined is directly due to the stimulus and encouragement of Dr. J. H. O. Roberts, medical superintendent, N. Wales Counties Mental Hospital, and to the zealous coöperation of Dr. E. Schwarz and Dr. R. S. Wilson, whose craftsmanship was so valuable in making the leucotome.

Medical Societies

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE

At a meeting of the society on June 20, with Dr. C. M. Wenyon, F.R.S., the president, in the chair, a paper on

Researches on 'Paludrine' in Malaria

was read by Prof. N. Hamilton Fairley, F.R.S. In the south-west Pacific, he said, mepacrine had been used successfully as a suppressive drug in malaria under conditions of jungle fighting. The annual malaria-rate in Australian troops in hyperendemic areas fell from 740 per 1000 in December, 1943, to 26 per 1000 in November, 1944. At Wewak, in New Guinea, however, a definite epidemic occurred in April–July, 1945, when 23·3% of the force had overt attacks. Here a strain of *Plasmodium falciparum* relatively resistant to mepacrine existed, requiring 2 tablets of mepacrine daily for its effective suppression, compared with the normally effective dose of 1 tablet daily; in infected volunteers this was not eradicated by the standard quinine, mepacrine, and pamaquin treatment followed by maintenance doses of mepacrine. Such resistance had very rarely been observed before. This strain was, however, responsible for only a part of the malaria at Wewak, most of the malaria casualties being caused by mepacrine-susceptible strains of *P. falciparum* and *P. vivax*, while the high rate of malaria casualties in this area was due to the failure of mepacrine discipline.

During the researches on malaria chemotherapy by the Medical Research Unit of the Australian Army, some 850 healthy volunteers had been experimentally infected with malaria, and in the experimental investigations on paludrine more than 200 volunteers had been experimentally infected, while many hundreds of troops with relapsing benign tertian malaria had been treated under controlled conditions with the drug. While taking 100 mg. of paludrine daily for three weeks after being infected with *P. falciparum* by infected mosquitoes volunteers developed no symptoms of malaria, parasites never being demonstrated in their blood either by microscopic examination or by subinoculation from the seventh day onwards of 200 c.cm. of blood into fresh volunteers. The negative subinoculation results on the seventh day after infection, and the subsequent failure to develop demonstrable blood parasites or attacks of malaria when drug administration ceased, indicated destruction of parasites in the pre-erythrocytic stage. In other words, the drug was acting as a causal prophylactic in falciparum infections.

While taking 100 mg. of paludrine daily for three weeks after being infected with *P. vivax* by infected mosquitoes, volunteers similarly developed no symptoms of malaria, parasites were never demonstrated in thick blood smears, and subinoculation of blood on the ninth day did not infect volunteer recipients. After ceasing paludrine, however, all these originally infected volunteers subsequently developed delayed attacks of overt vivax malaria. It was evident that paludrine was acting only as a partial prophylactic in these benign tertian infections.

Volunteers also received as many as 130 *P. falciparum* and 120 *P. vivax* infective bites while taking 100 mg. paludrine daily. During this period they were subjected to severe stresses and strains, including (1) long marches in hilly country in a tropical climate, from 30 miles in twenty-four hours to 80 miles in three days; (2) chilling by exposure in a freezing chamber; and (3) injections of adrenaline and insulin. The daily dose of paludrine was continued for four weeks after the last exposure o infection, which covered a period of two months. hroughout the three-month period no symptoms of malaria were noted and parasites were never demon-trable in thick blood smears. Some twenty-four to hirty-three days after the last dose of paludrine, overt ivax malaria developed but never falciparum malaria.

A single dose of 50–100 mg. of paludrine, given at 8, 72, 96, and 120 hours after exposure to heavy alciparum infection, acted as a complete causal prophy-actic, but 100 mg., given three hours before or 144 hours r more after exposure to infection, did not prevent vert malaria, indicating that the pre-erythrocytic parasites were much more susceptible to paludrine than were either the sporozoites or the asexual erythrocytic parasites. In larger doses the erythrocytic parasites ould be destroyed by the schizonticidal action, but it is doubtful whether paludrine exerts any lethal action on he sporozoite.

The practical conclusion reached from this and other experiments is that paludrine in a dosage of 1 tablet (100 mg.) twice weekly, given at three or four days' nterval, will entirely prevent falciparum malaria and will effectively suppress vivax malaria throughout the period of drug administration.

Normally *P. falciparum* appears in submicroscopic quantity in the blood from the seventh day after infection by mosquito, but three or four days usually elapse before parasites are demonstrable in thick blood films. Volunteers exposed to heavy biting with falciparum-infected mosquitoes and given 100–200 mg. of paludrine from the seventh to the twenty-first day were completely cured by the schizonticidal action of the drug; subinoculation of blood on the seventh day was positive and produced in the recipients attacks of malignant tertian malaria.

When hospital patients suffering from overt attacks of falciparum malaria received a course of 100 mg. of paludrine twice daily for ten days, the clinical response was satisfactory, parasites disappeared within two days from the blood, and 104 out of 105 patients were radically cured. No other drug is as effective as paludrine in the radical cure of malignant tertian malaria.

In relapsing vivax malaria the clinical response was in no way superior to that obtained with quinine or mepacrine. Insufficient time has elapsed to assess the proportion of radical cures. A three weeks' course of the drug followed by a maintenance dose of 100 mg. twice weekly for six months is regarded as holding out the best prospect of cure.

The outstanding quality of paludrine as a schizonticide is the smallness of the dose required to resolve a clinical attack of malaria. A single tablet (100 mg.) will lead to disappearance of symptoms and to disappearance of parasites from blood smears in overt attacks of malaria caused by either *P. vivax* or *P. falciparum*.

Though clinical cure is regularly attained with 100 mg., radical cure is not to be expected and recrudescence or relapse follows in a few weeks. The possibilities of this single-dose régime, however, open up an entirely new field in the chemotherapeutic control of malaria in hyperendemic areas, not only on account of its schizonticidal effect but also because of its extraordinary potency as a causal prophylactic in single doses of 100 mg. or less, given two to six days after infection.

Gametocyte production was not primarily affected by the drug. Provided the primary wave of asexual parasites was not terminated early, the secondary gametocyte wave followed its normal curve, but if asexual parasites were eliminated in the first day or two of fever, minimal gametocyte production resulted. In other words, in both *P. falciparum* and *P. vivax* infections, paludrine acts as a secondary and not as a primary gametocide. Gametocytes taken into the stomach of a mosquito from a carrier on the first day of paludrine therapy underwent normal exflagellation and fertilisation, with the formation of travelling vermicules which penetrated the gut wall and formed oöcysts. These oöcysts, however, did not grow normally, and they degenerated. Complete sterilisation of the infection resulted in mosquitoes fed on a carrier an hour after the first dose of paludrine had been administered. When mosquitoes were fed on a carrier on the second day of paludrine administration, gametocytes failed to develop as far as the oöcyst stage; this effect continued until paludrine administration ceased and the drug was completely eliminated from the blood of the carrier. Though paludrine does not directly inhibit the formation of gametocytes or modify the microscopical appearance of those already formed, complete sterilisation of the gut infection in mosquitoes (*P. falciparum* or *P. vivax*) results when 100–150 mg. has been administered to a carrier; this effect is not irreversible but persists as long as paludrine is present in the blood.

Paludrine in vitro acts on *P. falciparum* in the pre-schizont or schizont stage, inhibiting nuclear division and producing degenerative changes in the chromatin and cytoplasm. Similar changes were found in blood smears from patients infected with *P. vivax* and treated with paludrine. Interference with some enzyme or coenzyme system controlling nuclear division may be the method by which the drug adversely affects the multiplication of asexual parasites. A similar action on early exoerythrocytic forms would explain the negative subinoculation results and failure of the erythrocytic forms to appear in the blood at the normal time in volunteers infected with sporozoite-transmitted malaria while taking paludrine.

The difference between the effective therapeutic dose and the toxic dose is very considerable. Minor and transient toxic effects have followed the administration of 1 g. daily. These consisted of troublesome vomiting, which was common, and signs of irritation of the renal tract, which was rare. A transient increase in myelocytes with a maximal rise on the seventh to ninth day was often observed with this large dose. With lower doses, such as 300 mg. daily for fourteen days, no significant toxic symptoms were observed.

DISCUSSION

The President said that the evidence brought forward strongly suggested that the difference between *P. falciparum* and *P. vivax*, from the point of view of persistence of infection, lay in differences in their respective endothelial development, the first parasite passing through only 2 or 3 endothelial cycles occupying six or seven days, whereas the second had an endothelial stage persisting for several months with an indefinite number of cycles.

Brigadier J. A. Sinton, F.R.S., emphasised the potential importance of paludrine as a suppressive antimalarial drug among indigenous semi-immune populations, in whom probably relatively small doses at weekly intervals would be efficient.

Dr. D. G. Davey felt that the chemotherapy of the exoerythrocytic forms would give the answer to the problems of malaria therapy. Experiments on these lines, however, would require an organisation such as had existed at Cairns, but this centre had now shut down. Much human suffering could be relieved if a means could be found to continue such an organisation. Paludrine was only eighteen months old and more had been discovered about it than was known about mepacrine, although the latter drug was already ten years old at the beginning of the war.

Dr. C. C. Chesterman, pointing out the importance of children as reservoirs of infection, speculated on the effect of paludrine given from birth onwards. Would such a procedure be of ultimate benefit, or might it not, through inhibiting the acquisition of individual immunity, prove just the reverse? It was proposed to examine this question in a mission in Africa.

Dr. F. Murgatroyd wondered whether combining pamaquin with paludrine had any effect on lowering the incidence of relapse in benign tertian infections, as did pamaquin combined with quinine.

Dr. H. S. Stannus remarked that the evidence that paludrine acted by interfering with the normal nuclear division of the malaria parasite might have wider implications in cancer research.

Dr. J. D. KING, asked about the toxic effects of paludrine.

Professor FAIRLEY, in reply, thought it possible that in the presence of premunity the suppressive and curative dosage of paludrine might be considerably reduced and the intervals between doses increased. Premunity was bought, however, at a great price with high infant mortality, while chronic malaria in the older age-groups produced widespread ill health. If these grave effects could not be averted while at the same time retaining the advantages of allowing premunity to develop, it might be necessary to aim at complete causal prophylaxis and radical cure of overt malaria. As regards toxicity of paludrine he said there was a remarkable latitude between the optimal dose and the toxic dose. In benign tertian infections there was evidence that pamaquin and paludrine combined were more efficacious than paludrine alone, though delayed relapses still occur after a single short course of the combined drugs.

Reviews of Books

Diagnosis and Management of the Thoracic Patient

Editor: C. P. BAILEY, M.D. London: J. B. Lippincott. Pp. 334. 24*s*.

THIS symposium of articles which is published in the "American Practitioner" series serves a useful purpose in giving a clear exposition of some of the less-known facets of chest surgery, and an interesting and up-to-date account of American practice. In the surgery of pulmonary tuberculosis the chapter on resection gives the indications and potential complications of this adventurous undertaking. The technique of bronchial closure and the after-treatment of lobectomy and pneumonectomy are well discussed. The results in 32 cases were not uniformly successful, but as this form of surgery passes from the experimental to more experienced stages improved results may be expected. Another relatively novel procedure—cavernostomy—is also discussed as a useful operation in certain forms of tuberculous cavitation. The statistical section on carcinoma of the lung contains figures on incidence, metastasis, and morbidity; in a limited number of cases treatment by extirpation gives a hope of cure.

Transthoracic approach to the upper end of the stomach has certain advantages, and the possibility of maintaining an effective anastomosis between œsophagus and stomach or intestine has now made resection of lower œsophageal or gastric growths practicable. The results show that there is a considerable future in this branch of surgery. Among the commoner forms of chest disease, more space might have been spared to the suppurative conditions. Bronchiectasis, lung abscess, and chronic empyema are considered in some of their aspects, but the deliberate omission of acute empyema presupposes a standard of treatment that is rarely achieved in practice.

A Future for Preventive Medicine

EDWARD J. STIEGLITZ, M.S., M.D., F.A.C.P. London: Oxford University Press. Pp. 73. 6*s*.

IN this provocative book Dr. Stieglitz asks for a broad conception of the scope of preventive, or constructive, medicine, and regrets that the reciprocal effects of medicine and the technical, social, economic, and political changes in American life have not been appreciated. He recognises that perfect health is an abstraction, that the benefits of purely preventive measures are demonstrable only *statistically, not individually,* and that statistics have little or no emotional appeal. Almost all our public-health activity has been directed to obstetrics, child health, and the prevention of epidemic disease; now it is imperative to cultivate the fitness of the adult population and to reduce so far as possible incapacity due to such things as nervous and mental disease, cardiovascular disease, and the arthropathies. Many causative agencies are usually at work, and he divides these into predisposing, provoking, and perpetuating. He argues that attention must not be solely concentrated on provoking factors, as in the past. Since improvements depend on the coöperation of the individual, there is ample scope for enlightened health education. P and education are, indeed, fundamental in the conception of preventive medicine, for health can become a matter of inalienable right. Dr. Stieglitz under no delusions about the limitations of a St service designed to "give" health to the people by mea of legislation. The focus of attention is usually upon th administrative machinery, and any attempt to set up super-plan to dominate the future of preventive or curative medicine en masse becomes, in his view, simply a vicious impertinence. The true responsibility of society *is to make available the means by which health may be* pursued and conserved, remembering that each citizen must accept considerable personal responsibility.

An Introduction to Clinical Perimetry

(5th ed.) H. M. TRAQUAIR, M.D., F.R.C.S.E, consulting ophthalmic surgeon, Royal Infirmary, Edinburgh. London: H. Kimpton. Pp. 330. 36*s*.

IN spite of its title this book is a fairly complete guide to the subject. From the retina to the occipital cortex, the author gives an excellent account of those lesions, whether due to injury, disease, or abnormal metabolism, which affect the visual nerve paths, and therefore produce a visual field defect which can be recorded on a perimeter or Bjerrum screen. The subject matter is *non-controversial*, and has hardly been altered at *all in this* edition, but the anatomical terminology has been brought into line with modern usage. The production of the book has been much improved since its last war-time publication, and now its lucid print and wealth of illustrations leave nothing to be desired. One would have liked to hear Mr. Traquair's views on the nutritional amblyopia seen in large numbers in prisoners from Japan and the Far East; but the author has confined himself to accepted fact, and the exact lesion in nutritional amblyopia is still in dispute.

The American Pocket Medical Dictionary

(18th ed.) W. A. NEWMAN DORLAND, A.M., M.D. Philadelphia and London: W. B. Saunders. Pp. 1061. 10

"Big Dorland" is a well-tried companion of all who need to keep abreast of technical medical language. "Little Dorland," its junior by two editions as well as in size, is a plump convenient volume which will stand comfortably on the doctor's desk beside Martindale and *Clinical Methods*. It manages, by dint of smaller type and an absence of pictures, to be nearly as informative as its senior; but it must have been intended for a capacious American pocket measuring more than $6^1/_2$ in deep and 4 in. wide, able to take a book at least $1^3/_4$ in. thick.

The Modern Treatment of Diabetes Mellitus

WILLIAM S. COLLENS, M.D., chief of the diabetic clinic, Israel Zion Hospital, Brooklyn; LOUIS C. BOAS, M.D., assistant in the clinic. Springfield, Ill.: Charles C. Thomas. Pp. 514. $8.50.

IN this year of insulin's 25th anniversary the historical introduction to this book makes delightful reading. The authors classify diabetic patients, according to the severity of their disease, into nine groups, beginning with the obese mild diabetic and ending with the diabetic in coma. The doctor is shown how to calculate a diet for each type, and the insulin dosage for each of six types of case requiring this treatment is deduced from an appropriate glucose-insulin ratio. Not all will accept the usefulness of a single theoretical criterion of this kind—particularly for the child, the insulin-resistant case, and the case in diabetic coma—and at other points in the book theoretical considerations seem to outweigh clinical observation. The traditional stomach lavage for the vomiting of diabetic *ketosis is*, for example, condemned; the separate injection of soluble and protamine insulin in place of the mixed daily dose is advocated; and the pregnant diabetic is allowed to go to term. The authors believe that, with modern management, no uncomplicated case of diabetic coma should be fatal.

While the English diabetic may note with envy the detailed analysis of foods which have long been absent from his diet, his doctor may well be thankful that a national diabetic association has secured for his patients planned rations of protein and fat which usually make it unnecessary to calculate the proportions of these and of the total calorie requirements.

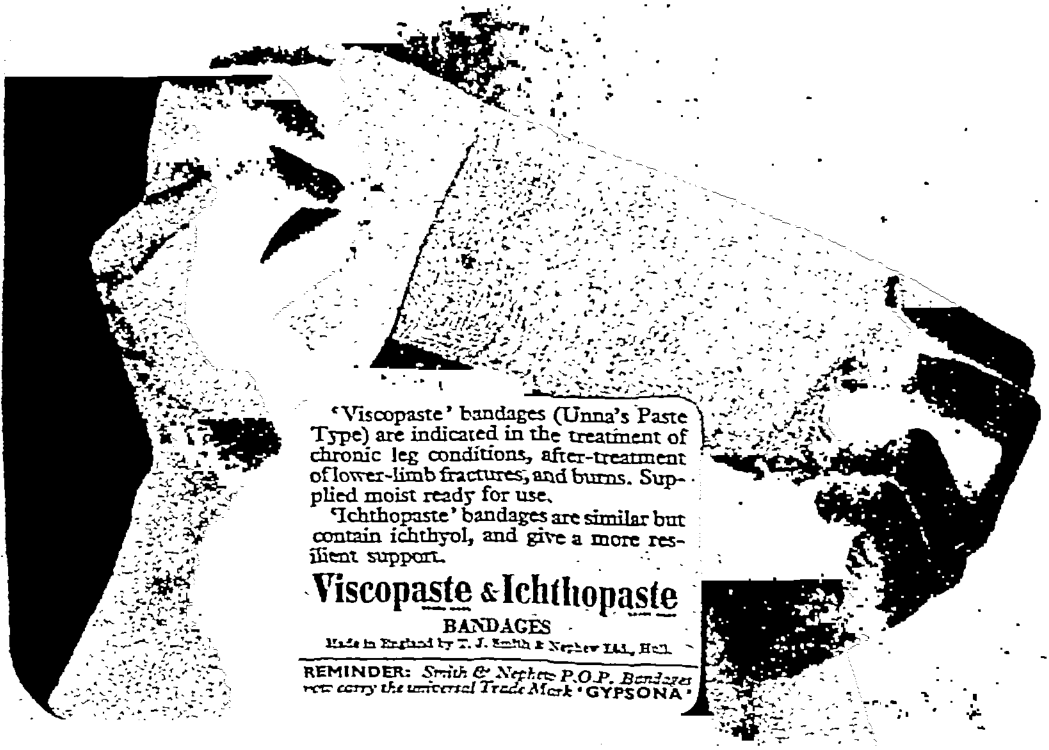
Vitamins in diseases of the nervous system

Condition	Indications	Therapeutic Agents
PERIPHERAL NEURITIS occurring in :— pregnancy diabetes alcoholism.	May indicate that the increased demand for vitamin B_1 is not being met.	**VITAMIN B_1 (Aneurin hydrochloride) Vitamins Ltd.:** 10 mg. or more daily by mouth or hypodermically.
SCIATICA facial neuralgia.	In the absence of pathological or structural lesions of a focal nature, high doses of vitamin B_1 may prove beneficial.	**VITAMIN B_1 (Aneurin hydrochloride) Vitamins Ltd.:** 10 to 100 mg. daily by mouth or by injection. Massive doses should be accompanied by either **BEFORTISS B complex capsules** or **BEMAX** to supply the other factors of the B complex.
HERPES ZOSTER and frontalis.	The pain of these conditions is lessened and the duration reduced by the addition of vitamin B_1 to other forms of treatment.	**VITAMIN B_1 (Aneurin hydrochloride) Vitamins Ltd.:** 10 to 100 mg. daily by mouth or by injection.
MÉNIÈRE'S SYNDROME	Relief has been obtained from combined therapy with vitamin B_1 and nicotinic acid.	**VITAMIN B_1 (Aneurin hydrochloride) Vitamins Ltd.:** Tablets 3 mg.—one thrice daily. **NICOTINIC ACID Vitamins Ltd.:** Tablets 50 mg.—once daily.
DEPRESSIVE PSYCHOSES	These states may be associated with a need for nicotinic acid.	**NICOTINIC ACID OR AMIDE, Vitamins Ltd.:** 50 mg. once or twice daily.

Further particulars of the various vitamin products are obtainable on request from

VITAMINS LIMITED

(Dept. L.X.J.1), Upper Mall, London, W.6.



'Viscopaste' bandages (Unna's Paste Type) are indicated in the treatment of chronic leg conditions, after-treatment of lower-limb fractures, and burns. Supplied moist ready for use.

'Ichthopaste' bandages are similar but contain ichthyol, and give a more resilient support.

Viscopaste & Ichthopaste

BANDAGES

Made in England by T. J. Smith & Nephew Ltd., Hull

REMINDER: *Smith & Nephew P.O.P. Bandages now carry the universal Trade Mark* **'GYPSONA'**

RADIOSTOL

TRADE MARK

(*VITAMIN* D_2)

Vitamin D_2 (calciferol), when sufficiently pure, may be administered in massive doses for its therapeutic effect in certain cases of arthritis and in lupus vulgaris. The purity of the product employed is of primary importance, exceptionally large doses being given in arthritis; also large doses over a considerable period are necessary in lupus. Radiostol is calciferol in highly-purified form, and it is eminently suitable for administration in high dosage.

For convenience in administration Radiostol is issued in solutions in oil containing 100,000 and 200,000 international units per gramme (for use in arthritis) and in capsules each containing 50,000 international units per gramme (for use in lupus). For routine use in the prevention and treatment of vitamin D deficiency states, Radiostol is issued in solution in oil, 3000 international units per gramme (Liq. Calciferol. B.P.) and in pellets each containing 3000 international units.

Details of dosage and other relevant information on request

Defence and attack—against chilblains

● Oral administration of calcium and vitamin D—as 'Ostocalcium'—is commonly used as a defensive measure against chilblains. A chilblain-free winter is quite possible when 'Ostocalcium' Tablets are taken regularly throughout the cold weather. If chilblains develop, however, parenteral therapy is more promptly effective. Injection of Colloidal Calcium with 'Ostelin' will frequently alleviate the immediate symptoms, and the parenteral attack can be consolidated by giving 'Ostocalcium' by mouth to prevent recurrence.

OSTOCALCIUM TABLETS

COLLOIDAL CALCIUM with OSTELIN

Manufacturers of
PENICILLIN

Colloidal Calcium with 'Ostelin' 6, 12 and 100 x 1 cc. ampoules 30 cc. bottles.

THE LANCET

LONDON: SATURDAY, NOV. 2, 1946

The Basic Salary

The House of Lords has fulfilled its function dmirably in its review of the National Health ervice Bill. Some had expected the course of the ill through the Upper House to be little more than formality; but even our abridged reports suffice o show that all the many points at issue were arefully re-examined. On those chiefly concerning octors the views of the profession were ably presented and carried proper weight. The Government ere persuaded to adopt a number of useful lterations in the Bill, and by several other amendents carried against the Government's wishes he House of Lords has compelled the Minister of Health and the House of Commons to think again. The Bill as now modified will shortly go back to he Commons, and if the changes made are not accepted there a further interchange of views will take place between the two Houses. In this the Government would have reason to be conciliatory: for unless an agreed text can go for Royal Assent before the prorogation of Parliament in about a week's time, he Bill will be lost for this session. Which would almost certainly mean that the introduction of the National Health Service was postponed.

The anxiety felt so widely about the responsibilities and powers of the hospital management committees[1] found formal expression—somewhat oddly—in an amendment declaring that these committees shall have the privilege of suing and being sued in respect of contracts into which they enter. The indignation of the metropolitan boroughs of London at the transfer of so many of their functions to the local health authority (the London County Council) was endorsed by an amendment obliging the L.C.C. to delegate these functions back to the boroughs. But the Government reverse that is of greatest interest to the medical profession was on the question whether general practitioners in the new service should receive part of their income in the form of a basic salary. Accepting the advice of Lord Moran and Lord Horder, and rejecting that of Lord Addison, the House of Lords in committee decided by 53 votes to 37 that "the remuneration of medical practitioners undertaking to provide general medical service . . . shall be fixed by the capitation method except in any cases where the Minister on the recommendation of the Medical Practices Committee considers that exceptional circumstances necessitate remuneration on a different basis."

Though the payment of doctors is one of the subjects still awaiting negotiation, Mr. Bevan has made it plain that he likes the "ingenious compromise" by which every practitioner would receive (1) a basic salary and (2) a capitation fee for each patient on his list. This arrangement, which was in not much favoured among those doctors who replied to the British Medical Association's questionary two years ago,[2] has several conspicuous advantages: it is an attempt, as the Minister put it, "to introduce into the system two desirable elements—the element of security for the individual, and the element of competition in order to sweeten and refresh the service." The basic salary would give confidence and support to the young man in the difficult days before he has enough capitation fees to provide a livelihood, and by varying its amount those responsible for the service could attract practitioners to unpopular areas, could compensate them for particularly hard conditions of work, and could recognise special experience or outstanding merit. The basic salary would bring in what Lord Addison called "a better way of paying people" which does not depend on the (not always edifying) competition for patients; but it would still leave the practitioner with a strong financial incentive to succeed in that competition—to remain, as Lord Moran puts it, on his toes. Thus the Minister's compromise is, as he claims, ingenious. Lord Horder was quite right, however, in saying that the arguments in its favour have made no impression on the profession as a whole, who "have got it firmly fixed in their minds that this is the most vital spot at which the Government can attack the independence of the doctor." The call to resist conscription into a "State salaried service" is one which rightly evokes a powerful response in medical hearts, and a major cause of resistance to the present Bill is that it empowers the Minister (if Parliament will consent to his regulations) to decide whenever he likes that all practitioners in the service shall henceforth be paid by salary alone. Moreover, though much can be said for diminishing, or even abolishing, competition for patients as well as for fees, it is not really essential to the establishment of the new service that practitioners should be paid partly by salary. Alternative expedients serving the necessary purposes could be devised, even if they proved a little inconvenient: for example, entrants to practice could be given maintenance grants; and a special bonus, or a higher capitation fee, could be paid for disagreeable work, and perhaps for special experience. Meanwhile, under the Lords' amendment, the effect of basic salaries, or even the abolition of capitation fees, could be further studied in areas such as the Highlands and Islands, where exceptional conditions clearly call for exceptional treatment. The profession can be convinced only by further evidence.

Very shortly, perhaps at the end of this month, the British Medical Association will ask each one of us whether we do or do not want our representatives to enter discussions on the regulations to be made under the Bill. If those who have to answer this question had heard the debates in the House of Lords they would hesitate long before replying in the negative; for they could scarcely fail to see that the vast and complicated project in which their help is invited is based rather on recognised necessities than on the political aims of the party now in power. The principal changes made in the scheme by Mr. Bevan when he succeeded Mr. Willink as Minister of Health concern the hospital services; and it is remarkable how much support these bold changes now receive from the hospital world. Apart perhaps from the embargo on the sale of practices, about which opinions differ, the only feature of the proposed general-practitioner services on which Mr. BEVAN can fairly be accused of being doctrinaire is his inclusion of a basic salary in the remuneration of all practitioners, *whether they need it or not.* He has now been given an opportunity to withdraw gracefully from this position, and for the sake of unity we hope he will take it. We agree with Lord HORDER that, when it comes to the point, the profession will do their utmost to work this Bill "be it good or bad." But they have yet to reach that point; and their utmost will be far more valuable if, before they reach it, every removable misgiving is removed.

Influenza B

IN 1940 FRANCIS and MAGILL independently described an influenza virus antigenically distinct from those encountered before. This has been christened influenza virus B—the original virus of SMITH, ANDREWES, and LAIDLAW being virus A. By retrospective examination of stored sera FRANCIS found evidence that virus B was concerned in an extensive influenza outbreak in California in 1936. Similar serological studies showed that some of the influenza present in England in the early months of 1939 was due to the same virus. Virus B has since been recognised as the cause of numerous outbreaks in North America, the West Indies, Argentine, Australia, and Britain. Clinically, influenza B seems to be indistinguishable from its fellow, influenza A. Earlier reports suggested that it had a more insidious onset and rather more catarrhal symptoms; but these differences have not proved to be constant. The disease has a more endemic character than A, turning up in minor local outbreaks but rarely causing major conflagrations. The larger mortality peaks in this country seem always to have been due to A. The Americans [1] have attempted to analyse curves of influenza periodicity on the assumption that two viruses, A and B, were responsible, A having a 2–3 year periodicity and B one of 4–6 years. There is likely to be a longer period between B outbreaks, because virus B is apparently a better antigen than A and gives a more durable immunity. In the laboratory, B viruses have hitherto been harder to isolate than A, since they do not readily produce symptoms in ferrets, and, as Dr. DUDGEON and his colleagues report on another page, may not be easily adapted to infect mice. Fortunately they can be persuaded, perhaps more easily than A viruses, to infect eggs; and Hirst's hæmagglutinin test can be readily applied to their recognition and study in the embryonic fluids of those eggs. As with virus A, there are serological varieties of virus B; but the importance of these races in epidemiology is still obscure.

The two papers in this issue should be read with this background of knowledge in mind. For the first time that we know of—and almost certainly for the first time in the last 15 years—virus B has been the main cause of a flu outbreak in this country. But, as both the papers show, its incidence has been capricious. The predilection for coloured victims, reported by Flight-Lieutenant JACKSON, is curious in view of the absence of reports from the U.S.A. of any specially heavy incidence among the negro population there. This tendency to hit part of a community heavily and another part hardly at all suggests that the conditions for its epidemic onslaught may be highly critical. If so, we may hope for much from preventive measures, whether these involve aerial hygiene or specific prophylaxis. Indeed FRANCIS and colleagues [2] have lately reported from vaccination which are more promising than hitherto recorded, and the experience of others America is said to be equally encouraging. We cannot tell yet whether such success against influenza B is due to greater antigenic potency of B vaccine or to the critical conditions necessary for its activity or to other circumstances in this particular trial.

The relation between influenza and pneumococcal pneumonia was much discussed [3] during the epidemic of 1917–18, when a purulent bronchitis sometimes leading to bronchopneumonia was the usual picture though a frank lobar pneumonia was occasionally seen. JACKSON encountered a high incidence of mild localising pneumococcal lobar pneumonia among his influenza patients in one unit in the Bahamas. The U.S. commission on acute respiratory diseases [4] has also recorded an epidemic of type I pneumococcal pneumonia in which many patients showed serological evidence of concurrent infection with virus B.

To the doctor seeing cases of influenza it does not immediately and obviously matter whether he is faced with virus A or B, or with "clinical influenza" due to neither. But to one who is studying epidemiology or attempting prevention the differentiation of this disease may be highly important.

Q Fever in Europe

THE observations made among Brisbane slaughter-house workers by DERRICK [1] in 1937 have now helped to reveal yet another cause of atypical pneumonia. He described 9 cases of a hitherto undescribed pyrexial illness in these men, and BURNET and FREEMAN [2] isolated the causative rickettsia, since known as *R. burneti*, from their blood and urine. DERRICK called this illness "Q fever," and its subsequent history has justified its intriguing name, though "Q" in fact merely stood for Queensland. In 1938 DAVIS and COX [3] in the United States reported the isolation three years previously of a filter-passing infective agent derived from the American wood-tick *Dermacentor andersoni*, in which it was hereditary. This organism was shown to be one of the rickettsias, and a case of laboratory infection with it in America ran a similar course to the Australian cases of Q fever. Careful comparison of the Australian and American strains of the *rickettsia* did not show any important difference between them, and accordingly the American name *R. diaporica*, given in allusion to the filtrability of the organism, was dropped in favour of *R. burneti*. Until recently the number of published cases was less than two hundred, of which the bulk came from Queensland, and apart from laboratory infections only one proved case had been reported in America.

In the original Brisbane outbreak the disease resembled mild typhus. The onset was sudden, with adache, malaise, fever, and pains in the limbs and ck. Headache was a constant and troublesome mptom, often interfering with sleep. The fever was mittent, usually ranging between 102° and 104° F, metimes ending by crisis between the sixth and ninth ys and sometimes by lysis after a fortnight or longer. he pulse-rate was relatively slow. Minor chest gns were noted in some cases. The Weil-Felix reac- on was negative throughout the disease, nor was ere any significant change in the blood picture. In laboratory outbreak at the National Institute of ealth, Bethesda, Maryland, patchy consolidation of e lungs, out of proportion to the physical signs, was own to be a feature of the disease. Accordingly *burneti* became recognised as an additional member f the group of agents, including various bacteria. he viruses of influenza and psittacosis, and the ungus *Coccidioides immitis*, capable of producing n "atypical pneumonia"

Now this disease has been reported in Europe,[4] or several outbreaks of atypical pneumonia among Allied troops in Italy and Greece, as well as in Panama, were established to be Q fever. The first outbreak to be investigated was in a British paratroop regiment early in 1945, during and after their departure from Greece; the remainder were in units of the U S. Army. Several strains of rickettsia were isolated and compared with each other and with the original Australian and American strains. Complete cross-immunity existed between all of them, and, though considerable variation in sensitivity was observed in antigens prepared from the different strains, all were believed to be examples of *R. burneti*. The epidemiology of the disease remains somewhat obscure. In Australia bandicoots form the natural reservoir of the disease, which is spread among them by ticks That cattle may acquire a natural infection has been shown by complement-fixation tests, and DERRICK suggested that the slaughter-house workmen had been infected by the inhalation of dust containing dried tick excreta brought in on the hides of cattle. No reservoir of infection or arthropod vector was discovered in the Mediterranean outbreaks. The evidence there was that the disease was a "place infection" and that case-to-case spread did not occur. The affected troops for the most part occupied billets, such as farmhouses and barns, where they were in close contact with cattle, rats, mice, and pigeons and with the accumulated dust of attics and haylofts. The hypothesis that the disease was acquired by the inhalation of the dried infective excreta of arthropods was consistent with the observed facts but awaits proof. Very few of the infected men complained of bites, which is evidence against, but by no means excludes, an arthropod vector.

Thus Q fever has a much wider distribution than was previously supposed. The possibility of cases being encountered in the British Isles should be borne in mind, since the incubation period (fourteen to twenty-six days) allows ample time for the journey from the Mediterranean to England before symptoms appear; one of the outbreaks reported by the Americans occurred in troops newly arrived in Virginia after a nine days' voyage from Naples. Imported hides might also be a source of infection. Laboratory tests for Q fever should therefore be considered in obscure pyrexias and pneumonias. The final diagnosis of the disease rests in the isolation of the rickettsias by guineapig inoculation with 5 ml. of venous blood taken in the first ten days of the illness. Affected animals develop a transient pyrexia after one to two weeks. They show little change at necropsy apart from an enlargement of the spleen. The rickettsias are sought for in smears made from the cut surface of this organ, but may not be found until several animal passages have been made. The organisms grow well in the yolk-sacs of chick embryos and can be readily demonstrated there after the inoculation of infected material.

Annotations

SIR HENRY DALE ON SECRECY

In his valedictory address as president of the Royal Society, Sir Henry Dale, O.M., a year ago spoke of the dangers arising from "security" regulations.[1] Last week he returned to the subject in a speech to the National Academy of Medical Science at Philadelphia,[2] when he suggested that war could be prevented by an international agreement not to carry on research under military secrecy. Nobody, he said, can guess how future discovery may increase the use of science as an agent of wholesale massacre; and nobody can predict what may be the result of committing the resources which produced the atom bomb to exploit other possibilities of scientific destruction. "National leaders," he continued, "may tell scientists that they must work in secrecy. We may be warned that its abandonment would make military secrets impossible and thus compromise the rights of national sovereignty. But a national sovereignty which means the right of any nation to secretly prepare the destruction of others also means the destruction of civilisation. We must tell our leaders that as scientists we are concerned not with the maintenance of military security or national sovereignty but with scientists' freedom. The universities of the world must unite in banning secrecy from their scientific work. I suggest that each nation's universities, and then the universities of all nations, should bind themselves never to accept contracts for research from the State or from industry, unless they are allowed to tell the results to the world. To the politicians I give this warning: if you insist on secrecy, many scientists will refuse to do the work involved."

CAPILLARY MICROSCOPY

PATHOLOGICAL conditions in living capillaries were first directly observed in 1879,[1] and much has since been written on the subject, but capillary microscopy of the nail-bed is still little used by clinicians, though Davis[2] points out that the technique is easy and gives no trouble or pain to the patient. Twenty-five years ago Jaensch[3] recommended that observation of the capillaries in early childhood should be a State measure, like vaccination, so convinced was he of the correlation between capillary pattern and mental development or physical disease. The government of Meresburg, Germany, was sufficiently impressed to make its school medical officers fill in a questionary on the capillary findings, psychophysical condition, and past and family histories of the pupils.

[2] Reported in the *Daily Express*, Oct. 23.

[1] Hueter, C. *Zbl. dtsch. med. Wiss.* 1879, 13, 225.
[2] Davis, E. *Amer. J. med. Sci.* 1946, 212 192.
[3] Jaensch, W., in Brugsch and Lewy's Die Biologie der Person, Berlin, 1931.

The procedure has suffered from difficulty in interpreting the microscopical appearances of the nail capillaries, especially, as Leader[4] remarks, for those of imaginative disposition. There is a very wide and varied range of the normal. Leader, and Wright and Duryee,[5] quote stunted mental and physical development, Raynaud's and Buerger's diseases, erythromelalgia, and other conditions as giving typical pictures, but such findings must still be suspected to vary with the observer. Davis emphasises the use of capillary microscopy in the discovery of petechiæ. Leader found no petechiæ in the nail-bed in patients with purpura and blood diseases, and some of the petechiæ illustrated by Davis would have been described by Wright and Duryee as mere dilatations of one or both arms of the capillary loop, but there can be little doubt that they were in fact extravasations of blood. Davis says that "petechiæ when first shed were obvious collections of red blood cells, later they became darker, and appeared as a rather homogeneous mass of pigment. If examined daily the petechiæ moved further and further away from the capillaries, and faded." In a previous paper Davis[6] gave an imposing list of conditions in which purpura had been noted. Of his 500 cases, 63% were symptomatic purpuras, and the largest categories were benign purpuras, cardiovascular diseases including congestive failure, rheumatic diseases, and bacterial infections. The degree of purpura was often very slight. In his present paper, 533 unselected patients suffering from a variety of medical conditions were examined by capillary microscopy, and 100 of them (18·4%) showed petechiæ in the nail-bed. It would be interesting to know what percentage of these petechiæ were in the arteriovenous type of capillary and what percentage in the arterial type.

More use could certainly be made of this simple investigation. Many of Davis's patients showed petechiæ in the nail-bed when no skin petechiæ were visible at any time, and in any of the numerous conditions in which purpura may be suspected the nail-bed should certainly be examined. The characteristic capillary pictures in vasomotor conditions, in preclubbing of the fingers, and in mental and physical retardation are easily memorised and sufficiently gross at times to rule out the need for imagination in their appreciation. Larger numbers of carefully observed cases must however be reported before the capillary pattern can provide a diagnosis without other stronger evidence.

FROSTED WARES

How to spread the surplus of foods during gluts over periods of famine has been mankind's problem from time immemorial. He has tried salting, pickling, smoking, drying, canning, cold storage, gas storage, and intense refrigeration, but all these processes are apt to affect both flavour and food value. Sometimes the flavour is improved, as in the canning of sardines. Usually it is changed, and even to some extent spoilt (e.g., canned apples). Rarely is the food value improved, though canners reasonably claim that the amount of vitamin C left in, say, canned asparagus or loganberries compares favourably with that of the raw materials bought on the open market and cooked at home. The ideal method of food preservation would deliver the food to the table in a state looking and tasting like the fresh material and with its food values unimpaired. The modern technique of "frosting" comes near to that ideal.

In England the technique had made some progress before the late war, when quick-frozen peas and fruits were already on the market. The impact of war brought quick freezing to a standstill, but operations were resumed in the spring of this year. In the United St the process has gone so far ahead that the housewife w likes to bake her own bread but hates the prelimina can buy frozen dough from the "stores" and only ha thaw it and put it in the oven. The American moth mustering her family for the midday meal, now cal "Get ready, everybody. Dinner's almost thawed ou Before, however, we can all enjoy the luxury of fro foods the special refrigerators must be installed by d tributors. None the less, one British firm[2] is going and soon will be offering us french beans, runner bea garden peas, and sliced cucumbers out of season much the same appearance and flavour as they wou have in season. When restrictions are removed, frost strawberries, raspberries, blackberries, and curran will be offered to the purchaser in much the same way.

The method for peas is to shell, blanch, and gra them. The blanching (which consists in heating them f $1^1/_2$ minutes to a temperature of 185° F) is necessary destroy enzymes, particularly the oxidases. The grade peas are weighed into cartons, and the wrapped carto are then passed to the air blast tunnel, where they me a current of air cooled to –35° F. On emerging from th tunnel they are stored at 0° F. Months afterwards th peas when thawed are difficult to distinguish from fres garden peas. Moreover their vitamin A is unimpaire and their vitamin C, when cooked, is much the same a that of home-cooked or of canned peas. The techniqu is young in this country and must make its way agains formidable obstacles; but in the United States, where it is older and has been encouraged rather than discouraged by war conditions, some say that it will not be long before the consumer's choice will be about equally divided between fresh, canned, and quick-frozen (i.e., frosted) foods

FIELD MARSHAL MONTGOMERY ON MORALE

IN his Lloyd Roberts lecture at the Royal Society o Medicine last Monday Lord Montgomery spoke o Morale, with Particular Reference to the British Soldie Training, he said, must from the first be directed to th selection of leaders and the infusion of discipline I battle, the characters of some grow firmer, while th characters of others are disintegrated by fear or fatigu Morale is a mental quality which maintains huma dignity and develops latent heroism; high mora draws a man forward against his own desires. It is n toughness, though tough men may occasionally perfor isolated acts of bravery.

Four basic factors are essential to high moral leadership, discipline, comradeship, and self-respec Good morale is impossible without good leaders; men are frightened at one time or another, and th they band themselves together and seek a leader. Fe makes men sluggish and indecisive, and the leade power depends on his capacity to cut through this fe paralysis by decision; the nature of the decision is le important than the fact that it is made and announc with confidence; the junior leader's greatest asset an ability to act normally in abnormal condition and to think rationally when his men have ceased think. The object of discipline is the conquest of fea whether fear attacking through the imagination as by the sight of a corpse at the roadside—or fe promoted by periods of inaction. The awareness danger, which is the basis of fear, can be partly ove come by teaching the soldier to lose his individualit and to think of himself as a member of a large bod of men, such as a battalion. To give of their best me must be united; and obedience is essential so th they comply with orders which run counter to the instincts. Discipline implies, too, a sense of duty whic for the soldier in battle, extends only to the men arou

aim. From discipline is bred comradeship; war is a rough and dirty game, but not necessarily grim. Comradeship, which is based on affection and trust, fosters good will; it is a great antidote to fear. All men have a touch of nobility, and friendship causes them to give of their best; it fills a man with warmth and strength when he feels cold and weak. The fourth essential—self-respect—may grow out of the first three. It implies an attempt to maintain personal standards. Efficiency is inseparable from self-respect; and confidence grows in the man who feels he is trusted.

Devotion to a cause is not, in Field Marshal Montgomery's view, essential to high morale. "I don't believe most soldiers are influenced by causes. I think soldiers fight for reasons which have little connexion with abstract ideas." It is true, he said, that no nation can fight an unpopular war; the soldier must be convinced of the rightness of the cause, and sometimes passive acquiescence must be altered to enthusiasm by encouragement of morale. To this rule there are some exceptions; a few officers and men are deeply moved and sustained by a cause which is, for them, more important than the ordinary components of morale.

It is possible, but difficult, to have high morale without one or more contributory factors, such as success; high morale is possible in defeat but not in long periods of defeat, while success enhances confidence in leaders and the high command. Regimental tradition may help, though in battle the soldier is concerned essentially with the present rather than with the glories of the past. Domestic worries can lower morale by making a soldier think of home and all it implies. Good administration and propaganda can also help to increase morale.

There are dangers in deliberately fostering a superb morale, because the soldier comes to think not only that he can do no wrong but that his leaders also can do no wrong; but "if the British soldier's heart is steeled, there is nothing you cannot do."

CANCER OF THE CORPUS UTERI

ON Oct. 25 at a joint meeting in London of the British Institute of Radiology, the Faculty of Radiologists, and the radiological section of the Royal Society of Medicine, Prof. J. Heyman, of Stockholm, described the radium "packing" technique used for cancer of the corpus at the Radiumhemmet since 1934. The cavity of the uterus is packed with multiple small tubes containing 8 mg. of radium element enclosed in additional filters which are cylindrical in shape and of varying sizes and thicknesses. The number of radium tubes used and the size of the filters depends on the size of the uterine cavity, while the time varies according to the amount of radium used. The method is designed to deliver approximately the same dose of radiation to the uterine muscle in all cases, irrespective of the number of applicators required to pack the cavity. Two treatments are given at an interval of three weeks, and in addition one vaginal dose of radium is applied on one of these occasions.

Professor Heyman said that of every 100 cases of uterine cancer seen at the Radiumhemmet 20–25 may be cases of cancer of the corpus. When concentration of cancer cases at large centres, as is the rule in Sweden, becomes general in other countries, this greater incidence of cancer of the corpus is likely to become more apparent, and in all probability the number of technically inoperable cases presenting themselves for treatment will form a larger proportion of the whole. Formerly hysterectomy was the treatment of choice for all but very advanced cases, but treatment is now primarily by radiotherapy. When operation is combined with radiotherapy it is the radiotherapy which plays the most important part. Only in certain cases, such as cancer of the corpus associated with large uterine fibroids, is hysterectomy the primary treatment. The operation is also performed where radiotherapy has failed, and in these it is found that there is no difficulty in removing the irradiated uterus and that a subtotal hysterectomy is sufficient.

Hysterectomy, in Heyman's view, is by no means a harmless procedure in patients over fifty years of age. In all the world literature he has found only 4 reports which include as many as 100 cases treated by hysterectomy over five years ago. Among these there is a relative five-year survival-rate of 40 to 50%, the absolute five-year survival-rate not being given. From these figures it appears that hysterectomy in the treatment of cancer of the corpus is less successful than is generally taught. At the Radiumhemmet radiotherapy is established as the primary method. The packing technique has been in use since 1934 and a five-year survival-rate of 64·9% has been obtained in cases so treated. No comparison has been possible with cases treated by hysterectomy followed by deep X-ray therapy because of the lack of significant figures published. Indeed comparable groups of cases treated primarily by hysterectomy or by radiotherapy are difficult to obtain. For example, many cases thought to be operable are found to be inoperable. Similarly some of the cases regarded as inoperable and treated by radiotherapy may in fact have been operable. The position appears to be that in the early operable cases no firm conclusion as between primary radiotherapy and primary hysterectomy can be drawn. But in groups comprising cases of cancer of the corpus in various stages of the disease, the results of radiotherapy show, in Professor Heyman's opinion, a definite superiority over those of hysterectomy alone.

RHEUMATISM IN SWEDEN

Prof. J. Axel Hojer, chief medical officer to the Royal Swedish ministry of health, addressing the Heberden Society in London on Oct. 26, said that up to 1925 the policy in Sweden was to treat rheumatism at isolated units. From 1925 onwards this policy had been reversed, with increasing concentration on centres, and latterly on university centres. In 1943 15% of the population had sought medical advice for rheumatic complaints. An additional 3000 beds were needed for the treatment of rheumatism and 2000 were to be set up at once. The proposal was to allot 500 beds for acute cases and 500 for chronic cases. The other 1000 beds would be in institutions for the chronic sick and in aftercare institutions; and about 20% of the beds would be in simple buildings, designed for patients not requiring much nursing attention. These could be built at half the cost of ordinary hospitals, and would be cheaper to operate. In another ten years, altogether 14,000–20,000 beds would be needed for the treatment of chronic diseases of old age, including rheumatism; at the moment only a third of this number was available. For outpatients, the country needed additional social workers, and more rural doctors and nurses to care for patients in their homes; at present Sweden had one doctor for every 1600 of the population. He hoped that the dearth of doctors and nurses would be corrected in another 10–15 years. In Stockholm a new rheumatism research institute was to be opened soon, and a further research centre was planned for Upsala.

Sir Wilson Jameson, chief medical officer of the Ministry of Health, said that news of experience and plans in Sweden was particularly welcome here at the present time. The Empire Rheumatism Council had had a difficult, and often thankless, task. The Ministry of Health could, he suggested, contribute much to further progress, since the best hope lay in an epidemiological and clinical approach.

THE next session of the General Medical Council will open on Tuesday, Nov. 26, at 2 P.M., under the chairmanship of the president, Sir HERBERT EASON, who will deliver an address.

questionary on the capillary findings, psychophysical condition, and past and family histories of the pupils.

The procedure has suffered from difficulty in interpreting the microscopical appearances of the nail capillaries, especially, as Leader [4] remarks, for those of imaginative disposition. There is a very wide and varied range of the normal. Leader, and Wright and Duryee,[5] quote stunted mental and physical development, Raynaud's and Buerger's diseases, erythromelalgia, and other conditions as giving typical pictures, but such findings must still be suspected to vary with the observer. Davis emphasises the use of capillary microscopy in the discovery of petechiæ. Leader found no petechiæ in the nail-bed in patients with purpura and blood diseases, and some of the petechiæ illustrated by Davis would have been described by Wright and Duryee as mere dilatations of one or both arms of the capillary loop, but there can be little doubt that they were in fact extravasations of blood. Davis says that "petechiæ when first shed were obvious collections of red blood cells, later they became darker, and appeared as a rather homogeneous mass of pigment. If examined daily the petechiæ moved further and further away from the capillaries, and faded." In a previous paper Davis [6] gave an imposing list of conditions in which purpura had been noted. Of his 500 cases, 63% were symptomatic purpuras, and the largest categories were benign purpuras, cardiovascular diseases including congestive failure, rheumatic diseases, and bacterial infections. The degree of purpura was often very slight. In his present paper, 533 unselected patients suffering from a variety of medical conditions were examined by capillary microscopy, and 100 of them (18·4%) showed petechiæ in the nail-bed. It would be interesting to know what percentage of these petechiæ were in the arteriovenous type of capillary and what percentage in the arterial type.

More use could certainly be made of this simple investigation. Many of Davis's patients showed petechiæ in the nail-bed when no skin petechiæ were visible at any time, and in any of the numerous conditions in which purpura may be suspected the nail-bed should certainly be examined. The characteristic capillary pictures in vasomotor conditions, in preclubbing of the fingers, and in mental and physical retardation are easily memorised and sufficiently gross at times to rule out the need for imagination in their appreciation. Larger numbers of carefully observed cases must however be reported before the capillary pattern can provide a diagnosis without other stronger evidence.

FROSTED WARES

How to spread the surplus of foods during gluts over periods of famine has been mankind's problem from time immemorial. He has tried salting, pickling, smoking, drying, canning, cold storage, gas storage, and intense refrigeration, but all these processes are apt to affect both flavour and food value. Sometimes the flavour is improved, as in the canning of sardines. Usually it is changed, and even to some extent spoilt (e.g., canned apples). Rarely is the food value improved, though canners reasonably claim that the amount of vitamin C left in, say, canned asparagus or loganberries compares favourably with that of the raw materials bought on the open market and cooked at home. The ideal method of food preservation would deliver the food to the table in a state looking and tasting like the fresh material and with its food values unimpaired. The modern technique of "frosting" comes near to that ideal.

In England the technique had made some progress before the late war, when quick-frozen peas and fruits were already on the market. The impact of war brought quick freezing to a standstill, but operations were resumed in the spring of this year. In the United the process has gone so far ahead that the housewife likes to bake her own bread but hates the pr can buy frozen dough from the "stores" and only thaw it and put it in the oven. The American mustering her family for the midday meal, now ca "Get ready, everybody. Dinner's almost thawed. Before, however, we can all enjoy the luxury of frost foods the special refrigerators must be installed by d tributors. None the less, one British firm [2] is going and soon will be offering us french beans, runner bea garden peas, and sliced cucumbers out of season much the same appearance and flavour as they wou have in season. When restrictions are removed, frosted strawberries, raspberries, blackberries, and currants will be offered to the purchaser in much the same way.

The method for peas is to shell, blanch, and grade them. The blanching (which consists in heating them 1½ minutes to a temperature of 185° F) is necessary to destroy enzymes, particularly the oxidases. The gr peas are weighed into cartons, and the wrapped cartons are then passed to the air blast tunnel, where they meet a current of air cooled to –35° F. On emerging from the tunnel they are stored at 0° F. Months afterwards the peas when thawed are difficult to distinguish from fresh garden peas. Moreover their vitamin A is unimpaired, and their vitamin C, when cooked, is much the same as that of home-cooked or of canned peas. The technique is young in this country and must make its way against formidable obstacles; but in the United States, where it is older and has been encouraged rather than discouraged by war conditions, some say that it will not be long before the consumer's choice will be about equally divided between fresh, canned, and quick-frozen (i.e., frosted) foods

FIELD MARSHAL MONTGOMERY ON MORALE

In his Lloyd Roberts lecture at the Royal Society of Medicine last Monday Lord Montgomery spoke on Morale, with Particular Reference to the British Soldier. Training, he said, must from the first be directed to the selection of leaders and the infusion of discipline. In battle, the characters of some grow firmer, while the characters of others are disintegrated by fear or fatigue. Morale is a mental quality which maintains human dignity and develops latent heroism; high morale draws a man forward against his own desires. It is not toughness, though tough men may occasionally perform isolated acts of bravery.

Four basic factors are essential to high morale: leadership, discipline, comradeship, and self-respect. Good morale is impossible without good leaders; all men are frightened at one time or another, and then they band themselves together and seek a leader. Fear makes men sluggish and indecisive, and the leader's power depends on his capacity to cut through this fear paralysis by decision: the nature of the decision is less important than the fact that it is made and with confidence; the junior leader's greatest asset is an ability to act normally in abnormal conditions and to think rationally when his men have ceased to think. The object of discipline is the conquest of fear, whether fear attacking through the imagination—as by the sight of a corpse at the roadside—or fear promoted by periods of inaction. The awareness of danger, which is the basis of fear, can be partly overcome by teaching the soldier to lose his individuality and to think of himself as a member of a large body of men, such as a battalion. To give of their best men must be united; and obedience is essential so that they comply with orders which run counter to their instincts. Discipline implies, too, a sense of duty which, for the soldier in battle, extends only to the men around

CARE OF CHILDREN

THE CURTIS REPORT

SOME 125,000 children, being deprived of a normal home life, have come within the terms of reference of the Curtis Committee.[1] This great company of children are provided for in many ways, and—in the usual British manner—according to widely differing standards. As it is with convalescent homes, with nurses in training, with hospital food, with treatment in sanatoria, so it is with children: those in authority are willing to do their best according to local custom and their own lights; but where lights are dim there are few precedents and no enthusiasm for borrowing a drop of oil from a neighbour. Thus Miss Myra Curtis and her colleagues found some children well placed and happy in good foster homes, and some cheerful and comfortable in homes, schools, and institutions; but they also found many living a dreary and stultifying life in "drab and scoured" surroundings, others overworked and weary in the service of the "home," and, worst of all, some neglected, dirty, ill-clad, and underfed, sharing workhouse wards with senile and mentally affected patients.

FORMS OF NEGLECT

If the overall picture is not as bad as it would have been a hundred years ago, yet it is a great deal worse than most of us have been complacently assuming; and it is right to repeat here some of the forms of neglect to which children are subject, including some of the worst examples, because the best safeguard against their perpetuation is well-informed public opinion.

The committee found that though nurseries for small children are often—perhaps usually—well run and well equipped, older children are likely to live in comfortless surroundings, with nothing to delight the eye, often with no convenient place to play, and with no toys or play materials, such as sand or clay. Their clothes are sometimes pleasant and individual (the sort of uniform which afflicted Rob when Mr. Dombey made a "Charitable Grinder" of him seems to have gone at last) but sometimes scanty or ugly. Their food is usually, but not always, adequate. They may be given no choice in their final career, being made, perhaps, into farm hands if they are boys, and almost inevitably into domestic workers if they are girls. Though it is often claimed that girls are "trained" in this work, in fact they may be given nothing but the dull chores, without training or responsibility in cooking or other skilled work. Owing to lack of domestic staff children in some homes are doing daily as much as four hours' domestic charing in addition to school-work.

In some homes run by religious bodies the need for relaxation is scarcely recognised, and children rise at six and go to bed at eight, spending the intervening hours in a solid round of domestic duties, school work, and religious exercises. In some girls' homes administered by a religious order 14-year-olds on leaving school are employed in the homes as laundry hands. In one case the laundry earned £85 a week by work for outside customers, while the girls seemed to be getting 2*s.* 6*d.* a week—"five shillings if they are very good."

The committee name the means of providing normal children with a home, in order of preference, as adoption, boarding-out, and institutional care. Yet one large voluntary body discourages adoption and insists on children who have been boarded out returning to the home for training in their teens—a rule naturally objectionable to good foster-parents who wish to take a share in settling "their" child in life.

Inspection should prevent serious abuses of children in homes, but the committee found repeatedly that the recommendations of inspectors had not been followed, and moreover that during the war inspection had often been desultory, years lapsing between visits.

WORKHOUSES AND HOMES

The worst examples of neglect were found children in workhouses, taken there as a tem measure, but kept there because no better quarters be—or had been—found for them.

In one century-old poor-law institution a family of normal children were sleeping on the same corridor as men and women and sharing a room with an unsightly hy- cephalic idiot. "They had been admitted in the middle of night, when their mother had left them under a hedge af eviction from their house. No plan appeared to have be made for them."

In a nursery (noted as exceptionally bad), linked with public-assistance institution, eight sick children were be nursed in a ward adjacent to the adult sick ward wh contained, among other chronic sick, a woman with advanc cancer of the face and also a child with chickenpox. Amo the sick children was a low-grade mentally defective gi who spent most of the day on a chair commode, and tw babies with rickets. The children wore cotton frocks, cotto vests, and dilapidated napkins. The room smelt foul. A premature baby had been isolated in a large very cold ward opposite. Some 16 healthy children in the same institution were living in a corrugated hutment, feeding, playing, an using their pots in a bare day-room devoid of toys. They wore dirty cotton or flannelette frocks and no knickers, and most of them had lost their shoes; their faces, but not their bodies, were clean.

Under the present law, healthy children over the age of 3 should only be received temporarily, or as an emergency measure, in public-assistance institutions; b the committee found many who had been there lon than the permitted 6 weeks, and some who had bee there for months at a time. These children were no attending school. The committee formed the opinio that in most such institutions the general care of childre was poor; the excuse offered was that good foster home are hard to find. But "the worst feature was ofte the complete failure to provide any kind of individual interest or notice."

The same weakness is found in some children's homes, whether provided by voluntary or municipal bodies. Homes are of various kinds: large *barrack* institutions left over from the last century; grouped "cottage" homes; small homes in ordinary dwelling-houses scattered through a district; and receiving homes, usually small, where children stay while permanent arrangements are being made for them. Some of the children in them are (like the children in workhouses) destitute and maintained under the poor-law, some are homeless children from evacuation areas, some physically or mentally handicapped, some in need of care or protection. Besides these children there are some, *including* war orphans, in foster homes and some in approved schools and remand homes. The ultimate responsibility for these children lies in several different departments: war orphans are the concern of the Ministry of Pensions: children cared for by local authorities come under th Ministry of Health; approved schools and remand homes, and also voluntary homes receiving public grants, are inspected by the Home Office; and voluntary homes certified as suitable for poor-law children are inspected by the Ministry of Health as well; mental defectives, most of whom are cared for by local authorities, come under the Board of Control.

REFORMS

Thus "the problem of providing for children deprived of a normal home life has not hitherto been dealt with as a single one." The committee have given much thought to devising means of simplifying and unifying the exercise of public responsibility. Such central control should apply, they think, not only *to the classes* of deprived children already recognised but to some groups who now fall outside the range of public care. These include children over 9 who have been taken der care by foster-parents for reward, children taken r foster-parents without reward, whether with a view , adoption or not, and children in voluntary homes not ow inspected by any public department. They think, ioreover, that when a child is found by a juvenile court o be in need of care or protection, from a local authority, hat authority should be obliged to accept the responsibility without having, as at present, the opportunity f refusal.

---

[1] Report of the Care of Children Committee. Cmd. 6922. H.M. Stationery Office. Pp. 195. 3*s.*

Responsibility at the departmental level, they suggest, hould lie with a children's branch of whatever department undertakes the work. This single central authority hould have "an inspectorate able to judge whether the onditions of the child's total welfare as a human being xist in a particular case." At the local-authority level he present defect is that no-one feels actively and personally responsible for the welfare of any individual hild. The report proposes that a single ad-hoc committee hould be formed with power to make recommendations and submit estimates direct to the council. Probably it would contain members experienced in public assistance, public health, and education, but it would not be subordinate to the committees in these subjects, or represent them. It would take over all the responsibilities which now fall to the councils under the poor-law, the Public Health Act, the Children and Young Persons Act, and the Adoption of Children Acts.

The welfare of the children would be directly in the hands of a specially chosen children's officer. "This," the committee affirm, "may indeed be said to be our solution of the problem referred to us." Usually, they think, this officer will be a woman, a specialist in child care, with high standing and qualifications, especially those of temperament, and with no other duties to distract her interests. Working with her should be an able staff, to each of whom she would allocate a group of children; they would be expected to act as the personal friends of these children, thus compensating them to some extent for the loss of direct parental interest and care.

It is interesting to compare this solution with that of Lady Allen of Hurtwood, made in her evidence to the committee[2] and again in the *Times* of Oct. 21. She points out that the children's officer (an unfortunate name, she considers) would be concerned only with the children —perhaps half the total number—who come under the care of the local authorities: children cared for by voluntary societies would be *outside* her scope. For such children the report suggests that "the head of an approved voluntary home" should be a suitable legal guardian; yet some voluntary homes, Lady Allen reminds us, discourage adoption and refuse to allow their children to be boarded out, though these are recognised as "the two most satisfactory methods of providing a substitute home for the majority of children." She wishes every child without a legal guardian, wherever placed, to become a ward of State by order of a court; and the State, working through local authorities or voluntary organisations, to be responsible for his proper care and upbringing.

The subject is intricate: where practice is so uneven, it is hard to see at once what should be the guiding principle. Possibly the recommendations of the Curtis Committee, if carried out, will help to prepare the way for Lady Allen's more comprehensive plan, in which the care of these children by the nation for the nation is recognised as a State rather than a local responsibility. Yet there is much in Mr. Kenneth Lindsay's view[3] that local care for local children comes nearer to the "parent" ideal which we all have in mind. In any case the issue is now clear, thanks to the painstaking work of the committee. Children are being deprived of the opportunity of normal mental, and in some cases of normal physical, growth; an immediate remedy is proposed, and should be tried.

THE PANEL CONFERENCE

THE annual conference of representatives of local medical and panel committees, held in London on Oct. 24 under the chairmanship of Dr. J. A. BROWN (Birmingham), discussed negotiations for a higher capitation fee.

MINISTER'S OFFER

Dr. E. A. GREGG, chairman of the Insurance Acts Committee, said that the committee, when it had asked for the Spens report to be implemented, had been met not with a refusal but with a proposal that discussion should include consideration of pay in another service not yet passed into law or approved by the profession. The Minister had been unwilling to listen to the argument that the I.A.C. was in no position to discuss this wider question. Finally the I.A.C., owing to the Minister's neglect to apply the terms of the report and in view of the grave inadequacy of the new 12*s.* 6*d.* capitation fee, had recommended insurance practitioners to place their resignation from the National Health Insurance service in the I.A.C.'s hands, and to authorise the I.A.C. to put in these resignations unless the Minister either applied the terms of the Spens report to the current capitation fee or referred the I.A.C.'s application to an independent body. This recommendation had been endorsed throughout the country. [Of those who replied, 95% were in favour.]

"I think," said Dr. Gregg, "that there must have been echoes of these things reaching Whitehall." The I.A.C. had received from the Ministry a further invitation, in which "some misunderstanding" was suggested. The misunderstanding, said Dr. Gregg, had been of the profession's temper. From the ensuing meeting the I.A.C.'s representatives had returned with a form of words they considered unsatisfactory; this included an offer of discussion on the factors common to current insurance remuneration and to remuneration in any future service, so as to apply the Spens Committee report to insurance remuneration. At the I.A.C.'s suggestion, the Ministry had issued another form of words:

> "The Minister is willing fully to apply the Spens report to the current capitation fee, with effect from Jan. 1, 1946, the increase of 2*s.* being regarded as a payment on account. To this end, he invites the Insurance Acts Committee to enter into discussions on the report forthwith, with special reference to the current capitation fee. The discussions will be conducted expeditiously."

Dr. R. W. COCKSHUT (London) claimed that a great victory had been won. "My only regret," he said, "is that it has taken place rather in private. Some say we must not kick a man when he's down. Why not? He's still breathing." The victory, he added, had been won not by the colleges but by the panel doctors; it was a victory for the British Medical Association.

The view of several subsequent speakers was rather that the first round had been won on points. Dr. GORDON WARD (Kent) confined his estimate of Dr. Cockshut's speech to an expression of relief that the general press was not represented at the conference. Had the I.A.C. any figure in mind for the forthcoming negotiations? The capitation fee of 15*s.* had been proposed only for a 100% service. "I should like the I.A.C. to say: 'Fifteen shillings or we go back to a special conference.'" (Cries of No!)

Dr. J. A. IRELAND (Shrewsbury) said that the 15*s.* mentioned in the Spens report did not apply at the present time; it had been based on the assumption of a 100% service and on 1939 figures, so that allowance must be made for betterment. There was no victory yet; but the Minister was in an awkward position. Speed in negotiation was vital; the profession was in a temper to resign.

Dr. GREGG said that the figure had not yet been determined; the I.A.C. was not tied to 15*s.* It was necessary to consider not only betterment but the addition, in 1942, of people with incomes up to £420 a year who normally could afford fees. He put a motion accepting the Minister's proposals, and a rider was added that it should be made clear that the words in the Minister's invitation "with special-reference to the current capitation fee" must not be construed as suggesting that the negotiators had any mandate to discuss anything relating to the future National Health Service. Rider and motion were carried without dissent. He then moved—

---

[2] See *Lancet*, July 27, p. 129. [3] *Times*, Oct. 23.

> that this conference authorises the Insurance Acts Committee to take any necessary action to secure the full and expeditious application of the Spens report to the current insurance capitation fee, such action to include, if the committee considers it necessary, the collection and use of the resignations of insurance practitioners,

and this was carried unanimously.

A Swansea motion seeking to impose a time-limit on the negotiations was defeated; and a proposal from Kent that withdrawal from the service, should it be deemed necessary, should be undertaken by national rather than by regional action was referred to the I.A.C. The conference agreed to seek the widest possible publicity for the reasons underlying its action, if withdrawal were decided on. Representatives congratulated the I.A.C. on its success so far.

THE REFERENDUM

Dr. A. **Beauchamp** (Birmingham) asked the conference to reaffirm its decision not to tolerate interference with the buying or selling of practices. Dr. **Guy Dain**, chairman of the B.M.A. council, said: "We are in a strong position. If you want to stand by your principles, you will vote [in the forthcoming referendum] against discussion of regulations with the Minister." The important simple principles were that any practitioner who wished should be able to enter the service, and that the right of appeal to the courts should be granted to doctors taken off the list. Dr. Dain quoted the example of Australia, where a Socialist design for a medical service had become a dead letter because the profession had refused to work it; but he did not want that to happen in this country. The council had decided to base the referendum on the single question, "Do you want the Negotiating Committee to discuss regulations with the Minister?" If the reply were no, the implication would be that the committee should take no further action to set up the new service until the principles had been conceded. At least two-thirds of the average doctor's income was derived from private practice; it should not be difficult, if the need arose, to maintain a reasonable standard of livelihood without the public service.

Dr. J. C. **Dixey** (Devonshire) suggested that the danger underlying a refusal to negotiate regulations was that the profession might eventually find itself in the same difficult position as that in which the Minister was now. The Birmingham motion was, however, carried unanimously.

Dr. Brown was re-elected chairman of the conference.

A SURGICAL OCCASION

CENTENARY OF THE ACADÉMIE DE CHIRURGIE

The Académie de Chirurgie of Paris, which celebrated its centenary on Oct. 9, is the successor of the Société de Chirurgie, founded in 1843, which itself succeeded the Académie Royale de Chirurgie, founded by Louis XV in 1731. Ten British surgeons, representing the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh, and the Association of Surgeons of Great Britain and Ireland, attended the celebrations in Paris, where they were the guests of the French government.

The centenary coincided with the 40th meeting of the Congrès Français de Chirurgie, which corresponds to the Association of Surgeons in this country, and on Oct. this opened at the faculty of medicine with a presi address by de Fourmestraux (Chartres), followed later a discussion on Pulmonary Embolism, led by Fonta (Strasbourg) and Redon (Paris). In the evening the British representatives were entertained to a government banquet in the magnificent rooms of the Mais des Alliés, formerly the house of Henri de Re Sir Max Page replied in French to a speech of welcome by M. Joxe, director-general of cultural relations in the ministry of foreign affairs, and two members of the delegation were presented with the honorary medal of the Académie.

On Oct. 8 a discussion at the faculty of medicine on conservation of the sphincters in operations for cancer of the rectum was opened by d'Allaines (Paris) and de Vernejoul (Marseilles), and in the evening the whole congress joined in a banquet at the Maison des Alliés. Next day the chief subject was the repair of peripheral nerves, with opening papers by Wertheimer (Lyons) and Merle d'Aubigne (Paris), and a contribution from H. J. Seddon (Oxford) and Ruth Bowden. In the afternoon the British party were received at the hôtel-de-ville by the municipal council of Paris under the presidency of Professor Basset, president of the Académie de Chirurgie, who reviewed the medical services of France and their possible developments in the future, dwelling particularly on their relations with the government. Addresses of congratulation were presented from the many countries joining in the congress, and afterwards the visitors went, as guests of the government, to the opera, where they were delighted by a superb ballet.

On Oct. 10 a sword of honour was presented to Prof. René Leriche on his admission as a member of the Institute of France. It was a happy ending to a great occasion, and all were glad to see this honour paid to one of the leaders of modern surgery. Thoughout their visit the British delegation were deeply touched by the reception accorded them by their surgical colleagues in Paris, by their generous hospitality, both public and private, and by the feeling of friendship they conveyed

CAMPAIGN AGAINST RHEUMATISM

THE NEW DEVELOPMENTS

At a reception held at Apothecaries' Hall last Monday to celebrate the tenth anniversary of the Empire Rheumatism Council, Sir **Wilson Jameson**, chief medical officer of the Ministry of Health, called on young doctors trained as general physicians to come forward and join with social workers and physiotherapists in tackling the medical, social, and economic problems of rheumatism. In the ten years since its birth the council had, he said, often and very properly been a thorn in the official flesh; it had done much to stimulate public interest and to guide medical opinion on rheumatism. Its plan for diagnostic and treatment centres, closely linked to the universities, was to be followed in general outline in the National Health Service. Centres were already functioning in London and various provincial towns, and the Nuffield trustees had made a generous grant towards putting the plan into effect. At present we did *not* know the causes of rheumatism and so could not classify cases properly; treatment was often of the hit-or-miss variety. The real aim was prevention, but the difficulties were too great to be overcome without Government help. Rheumatism was one of the big problems that the Government were to tackle in the new service. Sir Wilson Jameson deplored the lack of teaching on rheumatism in the medical schools.

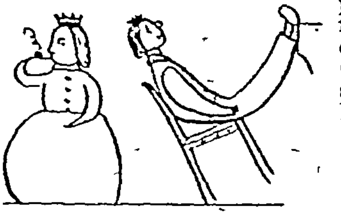
In welcoming the council's guests of honour, Lord **Horder** said that its ten years of work was at last bearing fruit. Dr. **Loring Swaim** brought greetings from the Pan-American Rheumatism Association, and Prof. J. A. **Höjer** and Dr. B. **Strandell** from the Royal Swedish ministry of health. Professor Höjer emphasised that institutes and beds were of little use in a campaign against rheumatism without the interest and coöperation of profession and public.

Ministry of Education.—Dr. J. E. A. Underwood now ranks as a principal medical officer, and Dr. R. Weaver as a senior medical officer.

In England Now

Running Commentary by Peripatetic Correspondents

AM preparing a thesis on "Character as Revealed Pipe Posture." It is not an ambitious project. To ;in with, it covers only the male segment of the population, with a few courageous exceptions, such as George Sand (when she ran out of cigars), Boadicea (in battle), Cleopatra (hookah), and Victoria (when Albert wasn't looking). Furthermore, it excludes the age-group 0–10, since rrelation of soap-bubble-pipe activity with the later d less mature fumigenetic pursuit is low. (Bubbles, ter all, are much more beautiful and much more citing than is smoke, while tobacco is considerably arer than soap.) My three character types, which rrespond vaguely with the introvert-extrovert cate-ries, are as follows:



'. . . when Albert wasn't looking . . ."

(a) The Drooper.

(b) The Jutter.

(c) The Tilter.

First, the drooper. This is a poor specimen who tempts to rationalise his feeble masseters by claiming iat it is easier to tell when one's pipe is out because ie has only to glance down into the bowl to see. This a fallacy, as a comparison of diagrams (*a*) and (*c*) ill show. A subgroup of this species smokes the pipe pside down. This is called over-compensation, a iisguided endeavour to convince the world that drooping very difficult. In a way, they are quite correct, but, s Voltaire sagely pointed out, "C'est difficile, mais ce 'est pas fumer!" referring, of course, to the fact that ie tobacco was never in the bowl of the pipe but was sually enjoying an autonomous and smouldering xistence on the front of the waistcoat. Burns of the tum 'ould be very common were it not for the fact that the rooper is usually also a drooler, a steady drip off the tem keeping the conflagration within modest limits. 'he mechanism is briefly this: the unconscious (by ind permission of C. G. Jung) neutralises the failure of he conscious via the salivary glands (by kind permission f I. P. Pavlov).

Now the jutter. This is usually a transition type: ither a drooper who is slowly integrating his personality r a tilter who is dementing.

The tilter. This posture comes easily to acromegalics nd to rear-admirals, particularly acromegalic rear-dmirals. The more erudite of my readers will have come cross the prototype of this class, one Popeye. This entleman exemplifies in full the character traits of the roup—doggedly determined in the face of overwhelming dds and underhand methods, staunchly loyal, and ommonly edentulous. Drooling is out of the question s all distillation and drainage is centripetal (by kind ermission of Sir Isaac Newton). There is only one hing to do when face to face with a foe of this description. sharp tap under the bowl of the pipe will deposit a lowing wad in the conjunctival sac of the opponent. ven should this be without effect on his composure, he nicotine will play havoc with his autonomic nerve-ndings and seriously impair his power of focusing.

* * *

Periarteritis nodosa, life-long jaundice, and leprosy vere just three of the conditions seen on a morning ound of an old poor-law infirmary which, since 1929, ias been a L.C.C. hospital; but it is not only in clinical naterial that municipal and county-council hospitals re approaching teaching-hospital standard. This round vas attended by six students, seconded for clinical raining; their coming has been acclaimed as a stimulus o thoughtful work. The staff is also well pleased to have two supernumerary ex-Service registrars—indeed, the wonder is that the work was ever done in this 500-bed institution with the normal establishment of 7 doctors, including the superintendent. But this plethora can be only transitory. Perhaps when it has passed, part-time clinical assistantships will be offered to general practitioners: their appointment would benefit the practitioner as much as the hospital; and why not give the local doctors a chance to attend clinical meetings? One complaint against the county council is the pay: an initial salary of under £800 for a resident deputy superintendent and of under £500 for a highly qualified A.M.O. cannot be counted as princely. Perhaps the council has been lucky in recruiting those who happen to believe in the form of service it offers; but even the faithful find that once married they must either quit or starve. This has resulted in a constant turnover of staff which has not made for smooth organisation; it has not been experienced in adjacent counties, where the value of professional services is assessed more generously.

* * *

This new system of medical grading in the Army is causing a lot of bother. The "good-enough-for-my-father" types are asking what was wrong with the old one. ("We won the war with it, didn't we?") The series of initial letters, each one neatly grading a bodily function, from feet (L) to eyes (EE—one for each eye), proves very confusing to those who can't remember whether L stands for Locomotion or Liver and S for Spleen or Stability. Our chief trouble has been naming the business of doing it all. Shall it be *pulheemising* or just plain (very plain) *pulheeming*. Neither is very euphonic, but pulheemising seems to have won. It sounds more distinguished to have been pulheemised than merely pulheemed. (The *s* is dropped by tacit agreement; there must be no suggestion of instability about the method even if there is about the subject.)

Like many other innovations this one has altered the meanings of a number of words. Thus a handsome profile no longer refers to a Barrymore physiognomy but rather to an unbroken series of 1's. The symbols largely remain a mystery to the uninitiated. A senior officer inquired whether it was the P or the U which recorded the results of his urine examination. Perhaps our saddest case was the Pioneer found waiting outside the M.I. room carrying a large envelope who, when asked his business, plaintively told us that he had "come to be pulverised"!

* * *

Our sub-chief is quite the most economical customer I have ever come across. It wasn't so bad when he confined himself to sticking up posters for the Ministers of Food and Fuel, but when he observed that, every time we gave a patient an electrical convulsion, some 100 volts were diverted for at least 0·3 of a second from our vital industries, I knew he wouldn't be content to leave it at that. And sure enough, the very next day he came out with his plan. We were to connect up the patient to the accompaniment of Liszt's E flat piano concerto on records. When it came to the bit where the triangle goes "ting-ting," we would press the button on the Cox-Cavendish. Next day no volts would be required. The records and Pavlov would do it all. The triangle would go "ting-ting," and, as a straightforward conditioned reflex, the patient would go tonic and clonic. The suggestion that we condition every patient in this way seemed feasible at first, till it was pointed out that the bells on our tramcars go "ting-ting" too. And before he got round to considering some other stimulus I had exposed the fallacy of the whole argument: if it were so easy to condition a reflex to the last stimulus experienced before Faraday, Galvani, and Co. asserted themselves, then all our edentulous patients should have had fits every night their wives said, "Have you taken your teeth out?" Such an incident has never come to my ears, and the whole thing provides, in my opinion, an excellent example of a theory based on a false premise. We still use the old-fashioned electrical method.

* * *

Neurosurgeon, after 6 hours of a craniotomy, "Sister, where's the clock?"

Theatre sister, "It's gone for repair, sir."

Anæsthetist, fairly sotto voce, "I shouldn't bother, Sister, stick up a calendar instead."

Letters to the Editor

THE BILL IN THE LORDS

SIR,—Few of your readers can have had the opportunity of hearing the committee stage on the Bill in the Lords; some comments from an eye-witness may therefore be of interest.

Considerable debate occurred on the relative powers of the regional hospital board and hospital management committee. Whilst it was abundantly clear that it is the wish of all parties, and the Government's intention, to decentralise to a great degree, the debate was at times quite unreal. A few clear words from the Government benches as to what was intended would have done much to disperse the miasma which continues to surround this important subject. Whilst everything reasonable should be decentralised to hospital committees, certain vital functions can only be carried out at regional level if we are to get the coördinated system we have been promised and not an anarchy of completely independent hospitals. Nor were Government speakers in possession yet of anything useful they could tell their Lordships about the delimitation of the regions. Even when the Health Bill becomes law we cannot know how the hospital service will work until these fundamentals of geography and function are made known.

The Leader of the Opposition indicated clearly that the House could only concern itself with revision—where revision was wise. It was necessary to make the Bill a better Bill. And at the committee stage some important revision was carried out. The vexed question of taking over the endowments was at last settled satisfactorily, the Government agreeing to take steps to allow the "sacred trusts" referred to by Lord Samuel to continue, and only to place endowments in a general fund when they had been given for the general upkeep of hospitals.

An important amendment that payment to practitioners should be by capitation fee only, and not partly by basic salary, was carried against the Government on the intervention of the president of the Royal College of Physicians. The persuasive and measured advocacy of Lord Moran, who was supported by Lord Horder, undoubtedly carried very great weight. Possibly not all doctors will be pleased with this amendment, but there will be complete unanimity at the stress laid by Lord Moran on the need to safeguard teaching and research in the teaching hospitals. In accepting this amendment the Lord Chancellor referred to the great authority which Lord Moran carried. Whatever be the fate of the various amendments before the Bill finally passes on to the statute-book it is clear that the Royal College of Physicians has been very worthily represented in this Council of State. By their policy of wisdom and moderation the college and its president, Lord Moran, have earned the gratitude of both the Government and the profession.

London, N.W.11. F. J. BENTLEY.

PERIODICITY OF INFLUENZA

SIR,—Last year we were warned that there was likely to be an epidemic of influenza in the winter of 1945–46. This forecast, which proved to be wrong, was no doubt based, in part at least, on the belief that the almost world-wide food scarcities and restrictions would favour such an outbreak. But was this belief justified? According to Dr. Kenneth M. Smith, of the Plant Virus Research Station at Cambridge (*Times*, June 1, 1944), "the rule that healthy organisms are more likely to stand infection than unhealthy organisms does not apply very strongly to plants and viruses." My studies of the periodicity of influenza lead me to believe that this "rule" may not apply to man and viruses either.

For the last seven years I have graphically recorded the incidence of all types of ailments among the patients in a large panel practice and I have found that every well-marked rise in the incidence of influenza is immediately preceded by a rising incidence of the common cold. This "common cold—influenza" sequence is the most striking feature of my records. Indeed so close are the two waves and so definite is their time relationship that I have come to regard them as parts of the same epidemic.

I have made another suggestive observation: well-favoured predominate among the patients the first (common cold) phase of an epidemic, the in the second (influenza) phase. Some years ago William Hamer[1] observed that during epidemics stout members of a family circle contracted colds later the slim developed influenza. But the point seems to be not merely whether patients stout or slim but whether their weight is stationary, or decreasing. My clinical observation as free from bias as I can make them—suggest that the main it is the "thrivers" who catch cold, "strivers" who develop influenza.

I have formed the hypothesis that the st of thriving favours the multiplication of organ living in the respiratory tract, thus producing the symptoms of an endogenous infection, the common col the resulting infection is spread as an exogenous infect which produces a more vigorous reaction label "influenza." If many people are thriving, and if enoug of them develop an endogenous infection at the same tim the weight of infection may be heavy enough to creat an epidemic of influenza among the strivers.

World experience of influenza during the late w supports my hypothesis. As you pointed out in yo leading article of April 13, 1946, influenza periodicity fairly stable up to 1941—the year when the world beg to tighten its belt—but since then it has been less stabl

Famine may prevail in Europe this winter. Certainly few will be well fed. In my view, however, the danger of serious epidemics of influenza is not now; it will come when the world enters the promised period of freedom from want. My observations suggest that it is in times of plenty, not during periods of privation that pandemics of influenza will occur and its periodicity be again stabilised.

If my hypothesis is true—and my own carefully collected data support it—many social scientists will have to review their premises. There is need, and opportunity, for parallel investigations by other observers. To those interested I recommend the study of sequences.

Halifax. ANDREW GARVIE

FOLIC ACID IN CŒLIAC DISEASE

SIR,—We can confirm the finding of Dr. Brody and Dr. Gore (Oct. 26) regarding the treatment of cœliac disease with folic acid. So far we have treated two cases, and in both there has been a striking clinical improvement and a reticulocyte response of over 25 % on a daily dose of only 5 mg. of folic acid. Both children, in addition to the typical clinical features, had "flat" glucose-tolerance curves and megaloblastic sternal marrows.

It is hoped to publish full details of these and other cases later; meanwhile, in view of the relative scarcity and high cost of folic acid, we feel that the efficacy of the smaller dose should be known.

H. W. DALTON.

V. K. WILSON.

Royal Manchester Children's Hospital.

CONVALESCENT HOMES

SIR,—May I, as an almoner, welcome your sug of Oct. 19 that there is need for a central agency to he and advise those who are concerned with the care of th convalescent patient? The needs of the convalescent have in this country never received the degree of study and attention that they require, and, though every almoner knows of a few excellent homes, the number is totally inadequate for the need. The regulation of vacancies through a central agency is by no means the only service that such a body could offer. Much work needs to be done in thinking out questions of feeding, furnishing, occupation, medical and social records, methods of sending reports back to the source of referral—to name only a few of the questions involved The establishment of a clearing-house for informatio and advice would remove much of the confusion, duplic tion of effort, and misunderstanding that so often aris between the management of the homes and the referrin agencies. To quote from a report recently published subject by the Hospital Council of Greater New k : "The red tape, the variations in restrictions, and failure to exchange medical and social data all ound to the discomfort and sometimes the neglect of patient."[1] I venture to believe that there are many, h among those who send patients to homes and those o receive them there, who would agree with that tement and would warmly welcome a lead towards ving their many problems. **M. J. ROXBURGH.**

lmoner's Office, Middlesex Hospital, London, W.1.

YCHONEUROSIS TREATED WITH ELECTRICAL CONVULSIONS

SIR,—In order that this correspondence may not be etracked by criticisms regarding data, I should like make the following comments. Owing to the exigency space my paper had to be severely limited, and, in rticular, tables giving in every case age, occupation, ration of symptoms, time in hospital, diagnosis, result of eatment, and period of follow-up had to be omitted.

I should also like to point out that, in this hospital, ery case is subjected to an extensive examination, and eatment is decided upon at a staff conference, when the ports of the psychiatric social workers, the psychologist, d if necessary the consulting physician, are considered relation to the psychiatrist's findings. I would stress e fact that we are not dealing with isolated cases, ferred merely for an opinion, but that we are endeavourg to cope with the vast problem of treating those fortunate members of a community of some 300,000, ho are completely crippled by psychoneurotic illness. any beneficial alterations can be effected in the home vironment, these are carried out through the agency our mental treatment department. We are completely sponsible for every patient long after he leaves spital, and no case is allowed to drift through lack accurate follow-up reports. I may add that my stateents concerning the absence of prolonged memory efects or intellectual deterioration are based on the llow-up records of over 2500 cases.

In conclusion, it may be of interest to note that, as x months have elapsed since I wrote my paper, the most cent case has now been followed up for at least fourteen onths. **W. LIDDELL MILLIGAN.**

St. James Hospital, Milton, Portsmouth.

SIR,—I have just been studying the history of sychiatry from Zilboorg's book, and I have come to the onclusion that should the value of the "intensive-lectrical-convulsive" treatment of the psychoneuroses s sponsored by the Portsmouth school be confirmed, we hall have attained one of the very greatest advances our specialty. For here were we old stagers plodding long painfully, treating our neurotics by teasing out onflicts, frustrations, and aggressions, by altering occupaons or modifying environments, when—lo and behold—e find that we have been wool-gathering, tilting at indmills, mystifying ourselves and our patients!

Apparently the difficulty of the psychoneurotic is a mple affair after all. It is merely another example of n electrical pattern in the brain gone askew; switch on e machine, change the brain-currents from anti-lockwise to clockwise, and—hey presto—the unfortunate fferer becomes happy. And what a great saving of time -ten sessions of five minutes each, as against perhaps 25 of one hour each. Instead of doubling or trebling e number of psychiatric outpatient clinics, as recomended by Dr. C. P. Blacker in his recent review (*Neurosis nd the Mental Health Services*), we can safely halve them; r analytic psychotherapy will soon become redundant, nd neurotics will be admitted direct to mental hospitals o have "all that nonsense knocked out of their heads."

And yet, is all this too good to be true? I feel that uch a radical discovery should be carefully verified in he very best research units of London, New York, and Moscow before we adopt it as a routine in all British ental hospitals.

I share Dr. J. Glaister's suspicion that we are dealing vith a serious regression in the history of the therapy of ental disorders. The fear I expressed early this year (*Brit. med. J.* 1946, i. 328) that an attempt will be made to replace long sessions of psychotherapy by short sessions of button-pressing is, alas, being fulfilled. I would stress again that the urgent social problem behind this trend is the scarcity of experienced psychotherapists.

Park Prewett Hospital, Basingstoke, Hants. **I. ATKIN.**

EPIDEMIOLOGY OF INFECTIOUS DISEASES

SIR,—One of the great problems in the epidemiology of infectious diseases is the mechanism by which infection survives through long inter-epidemic periods. Based on recent knowledge of the variability of the molecular structure of viruses the solution of this problem is here suggested.

It is noteworthy that human epidemics usually occur during a particular season of the year and that epidemic foci *often arise* simultaneously and apparently independently, suggesting some *activation* of previously acquired infection rather than direct case-to-case transmission. Shope (1943) has demonstrated that swine influenza virus, while in the lungworm, exists in a masked form and is totally non-infective until awakened to activity by some provoking stimulus. Furthermore, he maintains that the onset of a swine epizootic is determined not by the acquisition of the causative virus but by meteorological or physical conditions which favour its activation. A similar conclusion was also arrived at many years ago by Tomb and Maitra (1926) regarding the relationship of "non-agglutinating" intestinal vibrios to epidemic cholera. In an article entitled "A New Conception of the Epidemiology and Endemiology of Cholera" (1927) they wrote as follows:

> "We have therefore been driven to the unavoidable conclusion that the non-agglutinating (non-epidemic) vibrio takes on the agglutinating (epidemic) characteristic under certain biochemical-physical conditions [often seasonal] in the human intestine, the nature of which are at present unknown, and in this mutation or epidemic form is the cause of epidemic cholera. Non-agglutinating (non-epidemic) intestinal vibrios therefore in our opinion constitute the reservoir of cholera both epidemic and endemic."

In a previous article (1926) they also wrote:

> "During our investigations in the Asansol Mining Settlement [Bengal], we have met with several outbreaks of epidemic cholera in distant and isolated villages, the inhabitants of which had not been in contact either recently or remotely with any case of epidemic cholera. Spontaneous outbreaks of epidemic cholera have also been noted by other observers in other localities. Hitherto the explanation of such outbreaks has been that they owed their origin to some carrier of Koch's (infective) vibrio who existed unknown in the community. Our suggested explanation of such outbreaks now is that owing to favouring circumstances [often seasonal] the non-agglutinating (non-epidemic) vibrio changes into the agglutinating or epidemic form in one of the numerous chronic carriers of non-agglutinating vibrios in endemic areas [such as the Mining Settlement], the epidemic spreading in the usual manner by contamination of water and by contact."

The mechanism by which infectivity is increased or diminished in a virus (and by inference in bacteria also) is thus described by Fenton (1945):

> "Our best clue to the nature of gene mutations is furnished by viruses, those submicroscopic germs that cause colds, influenza, yellow fever, and a number of diseases in plants. They, too, are giant molecules containing hundreds of thousands of atoms that are linked in complex groups and series. For generations these molecules may be stable; then they abruptly change. Thus the virus which normally causes tobacco mosaic may add a few thousand atoms and become a variety that produces the much more virulent ailment known as acuba. Other modifications may cause a disease that kills the affected plant or make the virus so weak that its effects can barely be detected. Apparently a single virus strain may appear in any or all of these forms, shifting from one to another as atoms are gained or lost."

Parliament

THE BILL IN THE LORDS

Committee Stage Concluded

On Oct. 22 Lord Amulree moved an amendment to clause 28 in the National Health Service Bill providing that the care of old people should be placed directly under the control of the health authority. The Bill provided that all sick old people should be so cared for, and he feared that if we tried to separate old people who are sick from those who are healthy we should get into difficulties. In age the dividing line between sickness and health was small, and if there were to be any barrier between the two he thought the care of the older people would suffer. Today more and more old people had to live in institutions, and these did not come under a health authority. If, as was possible, it was found necessary to add some kind of sick quarters to these institutions there would be a danger that old people might tend to be kept there rather than removed to hospital. The Earl of Listowel said that the care of the aged who were not sick did not come within the *scope of the Bill, but he assured Lord Amulree that* it would be dealt with in forthcoming legislation which the Government intended to introduce for the abolition of the poor-law. They regarded that as among the most important social reforms which they hoped to carry out. The amendment was withdrawn.

Lord Llewellin moved an amendment to provide that medical practitioners who had to decide before the appointed day for the Bill to come into force whether they would enter the service should be given not less than three months' notice of the terms and conditions of the service. But Lord Jowitt, though in sympathy with the amendment, did not want to tie himself down in the Bill because difficulties might arise. The terms would be negotiated with representatives of the medical profession, who no doubt would keep their constituents acquainted with the matter as it proceeded. He hoped that it might be possible to give doctors more than three months' notice. Viscount Cranborne thought it difficult to leave the matter as it was in view of its extreme importance to the medical profession. The decision which *doctors would have to make would* affect the whole of their future lives, and it was only fair that Parliament should allow them adequate time for consideration. It would be an insult to the medical profession and to the skilful officials of the Ministry of Health to suggest that they could not devise terms and conditions of service in the period which would elapse before the appointed day. Lord Jowitt agreed that they ought to aim at six months' notice as a minimum, but he asked their Lordships not to put anything binding in the Bill in case there might be unexpected difficulties. He would, however, undertake to consult the Minister of Health and look at the matter again. The amendment was withdrawn.

BASIC SALARY AND CAPITATION FEE

Lord Llewellin moved to add the following subsection to clause 33 :

> The remuneration to medical practitioners undertaking to provide general medical services in pursuance of the provisions of this Act shall be fixed by the capitation method except in any cases where the Minister on the recommendation of the Medical Practices Committee considers that exceptional circumstances necessitate remuneration on a different basis.

As yet, he pointed out, no indication had been given of what proportion of the doctor's remuneration was to be by salary and what by capitation fee. He believed that the right way to remunerate the doctors was by capitation fee, though he realised there were areas where this would not be possible.

Lord Moran said that this matter had aroused the misgivings of many doctors who, like himself, were satisfied, generally speaking, with the hospital provisions of the Bill. The proposal to pay a doctor a salary required more justification than had hith been given. There could only be two reasons. it had been suggested, was that the Socialist before it came into office had seriously consider whole-time medical service with a basic salary, and the method proposed in this Bill had been adopted concession. If this was true it was not a good rea The other was a better one. It was said that any p titioner entering medicine might in his first year have financial difficulties, and that a basic salary £300–£400 a year might supply some measure of secur But was it *proposed* that the Ministry of Health go on paying doctors a basic salary *if they did* not any patients in their first year or two? On the oth hand, if the doctor got patients to the equivalent amou of the basic salary, then this measure of security wa no longer necessary. Not only was there very little to b said for a basic salary, but there was a good deal to b said for a capitation fee. In past years Lord Mor had been asked to advise the medical service of Navy and the Royal Army Medical Corps how to ob keen men, and the result of his investigations had sh that it was impossible, with many brilliant exceptions to keep men as keen in whole-time salaried service of that nature as in general practice where the competitive stimulant was present all the time. He was convinced that if there was anything approximating to a whole-time service great attention must be paid to incentive, and that was why he would like to see the whole of the remuneration paid by capitation fee and the basic salary dropped. It had been said there was something derogatory in competing for patients, but was this true? Would the Noble Lord on the Woolsack be demonstrating the development of his forensic skill, if instead of competing for briefs in his earlier years he had been the salaried servant of a corporation?

Lord Horder suggested that Mr. Bevan could do nothing more salutary, or more likely to further his happier relations with the B.M.A., than to accept this amendment. Several times during the committee stage the Government had given an assurance that there was no intention to nationalise the medical profession. But those statements might be made ad nauseam and there would still be firmly fixed in the minds of the medical profession the idea that that was the final intention of the Government and of the Ministry of Health. The doctors had not been impressed by the reasons given for part payment by a basic salary. They believed this to be the most vital spot at which the Government could attack the independence of the doctor, whether as a practitioner of medicine or as a man earning his living in a reputable fashion. To accept this amendment would assure those in charge of the Bill of a big element of extra confidence in the mind of the medical profession, and the Minister *had admitted* that without the coöperation of the doctors the scheme to fail. Lord Beveridge had said that the Bill was a one and he wanted to make it better. Lord Hor thought the Bill was a bad one, but he would like make it less bad. The doctors would do their best to work the Bill, good or bad ; they could not strike They must continue their work, and they must have State support in doing so. The doctor was *not* an altruist when he started in his profession ; he became an altruist in proportion as he *succeeded*. The medical services *in this country* had a great deal in their favour, and though it was the duty of the State to improve the machine, it was for the doctor to work the machine A willing worker would go a long way, an unwillin worker would go only a short way, and would not ev give to this health scheme the trial which it deserved.

Viscount Addison, who had been largely in char of the negotiations relating to the original capitatio lowance 30 years ago, admitted that he had been isappointed at the way in which it had worked. The hole tradition and practice of medicine was to frown n any unnecessary competition for patients, and he hought that was right; and the list system of payment ad by no means been beyond criticism, for inflated sts made detailed attention to patients difficult. It as because of the faults of the capitation system that he Government had adopted the plan in this Bill, nd not because they had any sinister designs. The ethod of payment could not be prescribed in the Act; must be left to negotiations, and he did not think it as possible to devise a system whereby payment ould be standardised. In remote districts the basic alary would probably have to be higher than in other laces. The Government were also convinced that ome stability was necessary for the young doctor ntering the service. Therefore he could not accept the mendment.

Viscount Cranborne, in announcing that the Opposiion peers intended to press the matter to a division, aid they felt that the balance of the argument was in avour of Lord Moran. He assured the Government hat in this question there was no element of political ias. They were trying to come to their decision on he technical efficiency of the new scheme. The Marquess of Reading held that the method of payment proposed y the Government was just and fair. Payment by apitation fees alone might lead to an undesirable cramble for patients. Could the Government say that t was not in their mind, in the present condition of ffairs, to embark on a wider scheme—a State medical ervice and State control of doctors? Viscount Addison eplied, "I can and do give that assurance." The mendment was carried by 53 votes to 37.

CHOOSING A PARTNER

On clause 34 the Earl of Munster moved an amendnent to oblige those concerned with filling a vacant nedical practice to bear in mind when choosing an applicant such considerations as family ties and the wishes of the medical partnership. The Earl of Listowel said it was the desire of the Government that partnerships should continue so long as the doctors themselves wanted to work in partnership. He thought that family or group relationships between an applicant and the area where he wished to practise would be a material factor which the executive council could not fail to take into account in advising the Medical Practices Committee about the application. Therefore, he doubted whether any express reference was needed in the Bill, but he would gladly consult with the Minister of Health to see if it was possible to draft a form of words for inclusion at a ater stage. The amendment was withdrawn.

PROHIBITION OF SALE OF PRACTICES

Speaking as a lawyer, Lord Maugham thought some of the penal provisions of clause 35 unfair and unjust to the doctors, and Lord Jowitt promised to look into some of the points again, notably the case described by Lord Llewellin of a doctor's house which was a biggish dwelling with surgery attached to it situated in a neighbourhood where most of the houses were small and occupied by tenants of the weekly wage-earner class.

THE NEEDS OF THE DEAF

Viscount Cecil of Chelwood moved an amendment providing for a supplementary service for the deaf, including the provision and maintenance of hearing-aids and the testing of hearing, running parallel to the supplementary ophthalmic service which is to be organised by the executive councils. Lord Horder regretted that the same prominence had never been given to defects of hearing as had been accorded to defects of sight. The Earl of Listowel said that the service which Lord Cecil wanted for the deaf would be better carried out, under present circumstances, by part II of the Bill, that was to say by the hospital and specialist services. Later it should be possible to set up hearing clinics in conjunction with health centres as part of the local health service. At present the amendment might even prejudice the limited service which could now be provided for the deaf. If this supplementary service were to be given by otologists and specialists they would have to be taken from the hospitals because there were not enough of them to provide for both types of service. The new and cheaper hearing-aid sponsored by the Government would be put into manufacture as soon as possible. The amendment was withdrawn.

RIGHT OF APPEAL

The Marquess of Reading moved an amendment to replace an appeal to the Minister, from a decision of the tribunal to exclude a doctor from any list or all lists, by an appeal to a High Court judge. The debate ranged over what Lord Jowitt described as a well-trampled battlefield with hardly a blade of grass left on it. He thought he was right in saying that there was no great demand for this amendment from the doctors. The Insurance Acts procedure had worked well. The Minister was entrusted with the duty of seeing that there was an efficient service, and he could not be deprived of the right to remove somebody whom he thought was unsuited. Viscount Cranborne wondered whether it would not be possible to give the doctor greater protection at the tribunal proceedings by allowing him to be represented by counsel and to call evidence, and Lord Llewellin suggested these tribunals should be heard in public and that the chairman should be a practising barrister of some years' standing. Lord Jowitt said he thought this a possible way out of the difficulty, though he suspected that the doctors themselves might object to public tribunals. He promised to do everything in his power before the report stage to see that the tribunal was a really satisfactory body. The amendment was withdrawn.

POSTGRADUATE TRAINING

On Oct. 23, the last day of the committee stage of the Bill, the Marquess of Reading moved an amendment to provide postgraduate courses for nurses employed in the service as well as doctors and dentists. Lord Horder declared that next to the doctors it would be the nurses upon whom the success of working the scheme would fall, and it had struck many people that there was inadequate reference to their work throughout this Bill. The nurse was as keen upon being kept up to date as the doctor. The discussion, Viscount Addison said, showed how badly the Government were treated. For the first time the State was making provision for postgraduate medical training, yet they received no thanks. London offered unique opportunities for postgraduate training and the Government intended to help the medical profession and the teaching colleges to develop them. The amendment related to a clause dealing with medical practitioners under part IV of the Bill who were not employed whole-time. Whole-time servants, such as nurses and any medical men who were employed whole-time, would be provided with facilities and would be expected to undergo regular refresher courses. The amendment was withdrawn.

DISCOVERY OF RECORDS

Lord Llewellin moved to insert a new clause compelling a council, board, or committee to produce documents and records. He said that all hospitals would henceforth be Crown property, and, as he understood the law, the Minister, or any officer acting under him, would be able to claim the privileges or prerogatives of the Crown. Assuming that there had been negligence he wished anyone who brought an action to have as much chance as they would have had if the hospital

Parliament

THE BILL IN THE LORDS

Committee Stage Concluded

ON Oct. 22 Lord AMULREE moved an amendment to clause 28 in the National Health Service Bill providing that the care of old people should be placed directly under the control of the health authority. The Bill provided that all sick old people should be so cared for, and he feared that if we tried to separate old people who are sick from those who are healthy we should get into difficulties. In age the dividing line between sickness and health was small, and if there were to be any barrier between the two he thought the care of the older people would suffer. Today more and more old people had to live in institutions, and these did not come under a health authority. If, as was possible, it was found necessary to add some kind of sick quarters to these institutions there would be a danger that old people might tend to be kept there rather than removed to hospital. The Earl of LISTOWEL said that the care of the aged who were not sick did not come within the scope of the Bill, but he assured Lord Amulree that it would be dealt with in forthcoming legislation which the Government intended to introduce for the abolition of the poor-law. They regarded that as among the most important social reforms which they hoped to carry out. The amendment was withdrawn.

Lord LLEWELLIN moved an amendment to provide that medical practitioners who had to decide before the appointed day for the Bill to come into force whether they would enter the service should be given not less than three months' notice of the terms and conditions of the service. But Lord JOWITT, though in sympathy with the amendment, did not want to tie himself down in the Bill because difficulties might arise. The terms would be negotiated with representatives of the medical profession, who no doubt would keep their constituents acquainted with the matter as it proceeded. He hoped that it might be possible to give doctors more than three months' notice. Viscount CRANBORNE thought it difficult to leave the matter as it was in view of its extreme importance to the medical profession. The decision which doctors would have to make would affect the whole of their future lives, and it was only fair that Parliament should allow them adequate time for consideration. It would be an insult to the medical profession and to the skilful officials of the Ministry of Health to suggest that they could not devise terms and conditions of service in the period which would elapse before the appointed day. Lord JOWITT agreed that they ought to aim at six months' notice as a minimum, but he asked their Lordships not to put anything binding in the Bill in case there might be unexpected difficulties. He would, however, undertake to consult the Minister of Health and look at the matter again. The amendment was withdrawn.

BASIC SALARY AND CAPITATION FEE

Lord LLEWELLIN moved to add the following subsection to clause 33:

> The remuneration to medical practitioners undertaking to provide general medical services in pursuance of the provisions of this Act shall be fixed by the capitation method except in any cases where the Minister on the recommendation of the Medical Practices Committee considers that exceptional circumstances necessitate remuneration on a different basis.

As yet, he pointed out, no indication had been given of what proportion of the doctor's remuneration was to be by salary and what by capitation fee. He believed that the right way to remunerate the doctors was by capitation fee, though he realised there were areas where this would not be possible.

Lord MORAN said that this matter had aroused the misgivings of many doctors who, like himself, were satisfied, generally speaking, with the hospital provisions of the Bill. The proposal to pay a doctor a salary required more justification than had been given. There could only be two reasons. it had been suggested, was that the Socialist before it came into office had seriously consider whole-time medical service with a basic salary, the method proposed in this Bill had been adopted concession. If this was true it was not a good rea The other was a better one. It was said that any p titioner entering medicine might in his first year or have financial difficulties, and that a basic salary £300–£400 a year might supply some measure of secur But was it proposed that the Ministry of Health sho go on paying doctors a basic salary if they did not any patients in their first year or two? On the oth hand, if the doctor got patients to the equivalent amo of the basic salary, then this measure of security w no longer necessary. Not only was there very little to said for a basic salary, but there was a good deal to said for a capitation fee. In past years Lord M had been asked to advise the medical service of Navy and the Royal Army Medical Corps how to ob keen men, and the result of his investigations had that it was impossible, with many brilliant exception to keep men as keen in whole-time salaried service that nature as in general practice where the competitive stimulant was present all the time. He was convinced that if there was anything approximating to a whole time service great attention must be paid to incentive and that was why he would like to see the whole of the remuneration paid by capitation fee and the basic salary dropped. It had been said there was something derogatory in competing for patients, but was this true? Would the Noble Lord on the Woolsack be demonstrating the development of his forensic skill, if instead of competing for briefs in his earlier years he had been the salaried servant of a corporation?

Lord HORDER suggested that Mr. Bevan could do nothing more salutary, or more likely to further his happier relations with the B.M.A., than to accept this amendment. Several times during the committee stage the Government had given an assurance that there was no intention to nationalise the medical profession But those statements might be made ad nauseam and there would still be firmly fixed in the minds of the medical profession the idea that that was the final intention of the Government and of the Ministry of Health. The doctors had not been impressed by the reasons given for part payment by a basic salary. They believed this to be the most vital spot at which the Government could attack the independence of the doctor, whether as a practitioner of medicine or as a man earning his living in a reputable fashion. To accept this amendment would assure those in charge of the Bill of a big element of extra confidence in the mind of the medical profession, and the Minister had admitted that without the coöperation of the doctors the scheme fail. Lord Beveridge had said that the Bill was a go one and he wanted to make it better. Lord Ho thought the Bill was a bad one, but he would like make it less bad. The doctors would do their best to work the Bill, good or bad; they could not strike They must continue their work, and they must have State support in doing so. The doctor was not an altruist when he started in his profession; he became an altruist in proportion as he succeeded. The medical service in this country had a great deal in their favour, and though it was the duty of the State to improve the machine, it was for the doctor to work the machine A willing worker would go a long way, an unwilling worker would go only a short way, and would not ev give to this health scheme the trial which it deserved.

Viscount ADDISON, who had been largely in charge of the negotiations relating to the original capitatio

Jowitt, in accepting the amendment, confessed he did not himself think it was necessary, but rienced people had expressed apprehension and t which he thought it best to remove.

FUNCTIONS OF THE LOCAL AUTHORITIES

ord Addington moved an amendment permitting al health authority to delegate some of its functions r clause 19 to borough councils. Lord Llewellin ted out that the transfer of these powers by the C. to their boroughs had been made mandatory by l Balfour of Burleigh's amendment. Lord Jowitt, eply, said he was much opposed to Lord Balfour's ndment. If it became law there would be two health norities in all the London boroughs, some working me service and some in another, and all the services e carried out in a health centre. He believed it would absolutely chaotic. Then again the amendment was y permissive. That infringed another principle which believed to be vital. "Do not leave it to the political ation of the future as to who is going to have these ers," he advised the Noble Lords. "Take your rage in both hands, and say that we put these powers n the major local authorities; there they are, there y stay, that is their job, and they cannot get out it." The amendment was withdrawn.

GENERAL MEDICAL SERVICES

n rejecting an amendment on the point Lord Jowitt e an assurance that doctors would have ample notice the terms and conditions of service before having to ke up their minds whether they were going to come or not. The Minister had agreed that they should aim a period of six months.

The Earl of Munster moved to add to clause 34 that

> The Medical Practices Committee shall, in a case where ersons have to be selected from a number of applicants, and he Minister shall, on an appeal in any such case have regard o any desire expressed by any applicant to practise with other nedical practitioners already providing general medical services n the area or part of an area concerned, and of any desire expressed y such other medical practitioners to take any applicant into ractice with them, and shall have special regard to the matters foresaid in cases where an applicant is related to any such other nedical practitioner.

ord Jowitt accepted the amendment, for he believed e Medical Practices Committee as sensible men would any case have regard to principles of this kind.

THE NEEDS OF THE DEAF

Viscount Cecil of Chelwood moved an amendment clause 41 to provide supplementary services for the af similar to those provided for teeth and eye cases. scount Addison promised to consider whether some ity of this kind to help deaf people could be inserted rlier in the Bill at the Third Reading, but he did not ink this clause was an appropriate place, because tside the medical profession there were few competent ople for dealing with defects in hearing, and therefore ere could not be a supplementary service for the deaf. eir treatment, including the provision of apparatus, ust be provided in hospitals and clinics. The amendment as withdrawn.

THE APPEAL TRIBUNAL

Lord Llewellin moved an amendment strengthening e protection given to a doctor appearing before the ibunal by giving him the following rights:

> of appearing, either in person or by counsel or solicitor or such other representative as may be prescribed, before the Tribunal and, in the case of an appeal, before a person appointed by the Minister; and
>
> of being heard by the Tribunal or the person so appointed and of calling witnesses and producing other evidence on his behalf; and that the hearing, whether by the Tribunal or the person appointed as aforesaid, shall be in public if the person who is the subject of the inquiry so requests.

le also later moved a further amendment to the seventh chedule providing that the chairman of the tribunal hould be a practising barrister or solicitor of not en years' standing. Both amendments were

DENOMINATIONAL HOSPITALS

Lord Jowitt moved the following new clause:

> . . . Where the character and associations of any voluntary hospital transferred to the Minister by virtue of this Act are such as to link it with a particular religious denomination, regard shall be had in the general administration of the hospital and in the making of appointments to the hospital management committee to the preservation of the character and associations of the hospital.

He was, he said, unable to accept Lord Iddesleigh's amendment inserting the words "and to the staff" after "committee." He agreed that it was essential that such officers as the matron and resident physician in a hospital of this kind should be of a particular denomination, but it did not matter whether the surgeon, for instance, was a Roman Catholic or a Plymouth Brother. The amendment was agreed to.

FROM THE PRESS GALLERY

Bricks and Brickbats

Opening a debate on housing in the Commons on Oct. 21, Mr. R. E. Manningham-Buller complained that thousands of people were enduring appalling conditions of overcrowding both in the towns and in the country, yet there had only been an advance of 21,149 sites on which development had begun since Mr. Bevan took office. Moreover, on the sites available, only 18,000 new permanent houses had been erected by the end of August. No-one expected the number of permanent houses to approach the pre-war monthly average of 30,000, but surely the Government's programme should have produced more than 5000 permanent houses in each of the summer months. The main reason for this sorry figure appeared to be the four-to-one rule in relation to local authorities and private enterprise, which meant that where a local authority was laggard nothing was done in the area. From the August report it was obvious that the local authorities had started twice as many permanent houses, and had finished less than half as many as private enterprise. This was not the fault of the local authorities, who were carrying a burden for which they had not been designed. Did the Government, Mr. Manningham-Buller asked, appreciate sufficiently the needs of rural areas? Between the wars something like 40,000 houses a year were built in the country, but only 3162 had been built in the rural districts while Mr. Bevan had been in office, and 3056 of these were produced by private enterprise. He warned the Minister that all his skill in rhetoric, and all his wordy vehemence would not save him from the wrath of the people who, but for his policy, might have been enjoying better housing conditions this winter.

Mr. A. Bevan, Minister of Health, claimed that the Government's decision last year to place the principal responsibility for the provision of houses upon the local authorities had been justified. By the end of August they had handed over to the building industry the job of building 155,000 permanent houses, excluding 54,000 licences given for houses for sale. He would continue to insist that houses should be built to let, and that the local authorities should be the only instrument for carrying out the housing programme. The only valid criticism of his policy was that no houses at all should be built for sale. The temporary housing programme had been so devised by the Conservatives that unfortunately its completion was now competing with the permanent programme. But the supply of building materials was now marching with the number of houses put into contract by the local authorities. One of the reasons for the slower rate of the permanent programme was the very success of the local authorities, who had put a higher number of houses into contract than the industry were able to handle, and therefore a comparatively small labour force was spread too thinly over a large number of houses.

Lady Megan Lloyd-George thought the number of workers still employed on bomb damage repairs disquieting compared with those engaged in building permanent houses. Above all, non-essential work must be ruthlessly cut. She appealed to the Prime Minister

inister of building to coördinate the

her ministries and to be responsible

had not been taken over by the Minister. Lord JOWITT agreed that it was most desirable that in proceedings against the Crown the litigant should have a very full measure of discovery, and he hoped that he would live to introduce the Civil Proceedings against the Crown Bill which would give a very wide right of discovery. But there might be a conflict of private interest with the public interest, and those concerned with Government business should have the right to communicate with each other freely without fear that their reports would be dragged out in a court of law. But subject to these reservations he would do what he could to secure that in actions relevant to this Bill there should be a complete measure of disclosure. Lord LLEWELLIN wanted words put in the Bill to ensure that documents which previously had always been compellable out of a hospital authority should also be compellable out of a regional hospital board. Lord JOWITT thought nothing further was needed in order to ensure this. The amendment was withdrawn.

THE SCHEDULES

On the third schedule, Lord LUKE moved an amendment to provide that before making appointments to fill vacancies on a regional hospital board the Minister should consult the board. Lord JOWITT accepted this amendment and also a further amendment moved by Lord Luke to provide that before filling vacancies on a hospital management committee the board should consult the committee. Lord Jowitt was, however, unwilling to agree that the boards and committees should have the right to appoint their own chairmen, but he promised to consider whether the boards might do so subject to the Minister's approval.

The Report Stage

The amendments made to the Bill in committee were reported in the House of Lords on Oct. 28. Lord LLEWELLIN then moved an amendment to ensure that doctors on the staff of a hospital, whether in an honorary or in a paid capacity, shall have the right to arrange for the treatment of their private patients there. Lord JOWITT confessed that he did not think the new words added anything to the Bill, but if they cleared up any ambiguity he was happy to accept them, and the amendment was agreed to.

ENDOWMENTS

Lord JOWITT moved to insert a proviso that endowments given to hospitals after the passing of the Bill but before the appointed day should be vested in the hospital management committees. The effect of the amendment, he said, was to put these gifts in the same position as if they had been made after the appointed day. Treasury control must always be rigorous, and it was right that it should, for all taxpayers were anxious that money should be saved where possible. But the running of a hospital on strict lines meant that many little comforts and amenities would not be provided unless the charitable came forward as they had done in the past. The Government were anxious to encourage them to do so, and he did feel that there was a danger that people would not give their money between the passing of the Act and the appointed day if they knew it would be carried over to a general fund. The amendment was carried.

Lord Jowitt moved an amendment to ensure that the Minister shall secure

> so far as is reasonably practicable, that the objects of the endowment and the observance of any conditions attaching thereto, including in particular conditions intended to preserve the memory of any person or class of persons, are not prejudiced.

He hoped their Lordships would agree that these words would give effect to what everyone wanted—that the wishes of the people who gave money to hospitals were not disturbed more than was necessary to make the hospitals efficient. The amendment was agreed to.

FUNCTIONS OF THE HOSPITAL MANAGEMENT COMMITTEES

Lord JOWITT moved to substitute the following section for subsection 2 in clause 12

> It shall be the duty of the hospital management com of any hospital or group of hospitals, subject to and in acco with regulations and such direction as may be given b Minister for the Regional Hospital Board, to control and that hospital or group of hospitals on behalf of the Board for that purpose to exercise on behalf of the Board such *functions of the Board relating* to that hospital or gro hospitals as may be prescribed.

The new subsection, like most of the other amendme was, he said, in accord with the undertaking given the Minister. But the new subsection differed from old in emphasis and form. The criticism levelled ag the Bill as drafted was that while the duty of the regi board was set out with precision, it was not really what the hospital management committee had to And that was true, for the Government intended to with the matter entirely by regulation. But they anxious that there should be the greatest measure decentralisation and devolution, and Noble Lords *not unnaturally been anxious to see this in the Bill.* must make it plain that what the committees *did th* were to do on behalf of and under the control of t boards, but he wanted to establish on the face of the that they had a real job of work to do. Viscou MAUGHAM, though he did not think the new amendm entirely carried out the desires of those who had interests of the hospital management committees heart, believed that with the help of this subsection regulations and directions which might be given by Minister would do so. But if the committees rema merely the agents of the boards they might not be to do anything without consulting the boards, and *was what the committees did not like.* He did not him believe that that was the intention of the Governm and he thought that what the Government had would ensure that the regulations and directions w be so framed that all the everyday work of the hos would be, by devolution, the business of the ho committee, to be carried out by them without con appeals either to the board or the Minister. LLEWELLIN was satisfied that the amendment did on the face of the Bill that the committees were given the control and management of the hospitals.

THE TEACHING HOSPITALS

Lord JOWITT moved an amendment to provide th the university with which a teaching hospital is associat should be provided with facilities for clinical teachi and research. He had found, he said, the joint pres of Lord Moran and Lord Horder irresistible when th asked him to put in something to show that one of t duties of a teaching hospital was to teach. He agr whole-heartedly and had therefore placed it in the fo front of the list of their obligations, for unless teachi was properly done the whole art and skill of the profess would go. He had, however, been unable to accept t suggestion of Lord Moran's amendment that the Gove ment were bound to carry out whatever the univers liked to order, for even universities might have rat *large and ambitious ideas.* He had therefore inclu in the amendment the words "Such facilities as appe to the Minister to be required for clinical teaching a research."

RIGHT OF DISCOVERY

Lord LLEWELLIN moved to insert at the end clause 13

> A Regional Hospital Board, board of governors or hosp management committee shall not be entitled to claim in a proceedings any privilege of the Crown in respect of the discov or production of documents, but this subsection shall be witho prejudice to any right of the Crown to withhold or procure t withholding from production of any document on the grou that its disclosure would be contrary to the public interest.

d Jowitt, in accepting the amendment, confessed , he did not himself think it was necessary, but erienced people had expressed apprehension and bt which he thought it best to remove.

FUNCTIONS OF THE LOCAL AUTHORITIES

ord Addington moved an amendment permitting ocal health authority to delegate some of its functions ler clause 19 to borough councils. Lord Llewellin nted out that the transfer of these powers by the .C. to their boroughs had been made mandatory by rd Balfour of Burleigh's amendment. Lord Jowitt,/ reply, said he was much opposed to Lord Balfour's endment. If it became law there would be two health horities in all the London boroughs, some working one service and some in another, and all the services be carried out in a health centre. He believed it would absolutely chaotic. Then again the amendment was ly permissive. That infringed another principle which believed to be vital. "Do not leave it to the political tation of the future as to who is going to have these wers," he advised the Noble Lords. "Take your rage in both hands, and say that we put these powers on the major local authorities; there they are, there ey stay, that is their job, and they cannot get out it." The amendment was withdrawn.

GENERAL MEDICAL SERVICES

In rejecting an amendment on the point Lord Jowitt ve an assurance that doctors would have ample notice the terms and conditions of service before having to ke up their minds whether they were going to come or not. The Minister had agreed that they should aim a period of six months.

The Earl of Munster moved to add to clause 34 that

> The Medical Practices Committee shall, in a case where ersons have to be selected from a number of applicants, and he Minister shall, on an appeal in any such case, have regard o any desire expressed by any applicant to practise with other nedical practitioners already providing general medical services n the area or part of an area concerned, and of any desire expressed y such other medical practitioners to take any applicant into ractice with them, and shall have special regard to the matters foresaid in cases where an applicant is related to any such other nedical practitioner.

rd Jowitt accepted the amendment, for he believed Medical Practices Committee as sensible men would any case have regard to principles of this kind.

THE NEEDS OF THE DEAF

Viscount Cecil of Chelwood moved an amendment clause 41 to provide supplementary services for the f similar to those provided for teeth and eye cases. count Addison promised to consider whether some y of this kind to help deaf people could be inserted lier in the Bill at the Third Reading, but he did not nk this clause was an appropriate place, because side the medical profession there were few competent ple for dealing with defects in hearing, and therefore re could not be a supplementary service for the deaf. ir treatment, including the provision of apparatus, st be provided in hospitals and clinics. The amendment s withdrawn.

THE APPEAL TRIBUNAL

ord Llewellin moved an amendment strengthening protection given to a doctor appearing before the unal by giving him the following rights:

> appearing, either in person or by counsel or solicitor or such her representative as may be prescribed, before the Tribunal nd, in the case of an appeal, before a person appointed by the linister; and
> being heard by the Tribunal or the person so appointed and of lling witnesses and producing other evidence on his behalf; nd that the hearing, whether by the Tribunal or the person ppointed as aforesaid, shall be in public if the person who is e subject of the inquiry so requests

also later moved a further amendment to the seventh edule providing that the chairman of the tribunal uld be a practising barrister or solicitor of not less than years' standing. Both amendments were accepted.

DENOMINATIONAL HOSPITALS

Lord Jowitt moved the following new clause:

> . . . Where the character and associations of any voluntary hospital transferred to the Minister by virtue of this Act are such as to link it with a particular religious denomination, regard shall be had in the general administration of the hospital and in the making of appointments to the hospital management committee to the preservation of the character and associations of the hospital.

He was, he said, unable to accept Lord Iddesleigh's amendment inserting the words "and to the staff" after "committee." He agreed that it was essential that such officers as the matron and resident physician in a hospital of this kind should be of a particular denomination, but it did not matter whether the surgeon, for instance, was a Roman Catholic or a Plymouth Brother. The amendment was agreed to.

Bricks and Brickbats

Opening a debate on housing in the Commons on Oct. 21, Mr. R. E. Manningham-Buller complained that thousands of people were enduring appalling conditions of overcrowding both in the towns and in the country, yet there had only been an advance of 21,149 sites on which development had begun since Mr. Bevan took office. Moreover, on the sites available, only 18,000 new permanent houses had been erected by the end of August. No-one expected the number of permanent houses to approach the pre-war monthly average of 30,000, but surely the Government's programme should have produced more than 5000 permanent houses in each of the summer months. The main reason for this sorry figure appeared to be the four-to-one rule in relation to local authorities and private enterprise, which meant that where a local authority was laggard nothing was done in the area. From the August report it was obvious that the local authorities had started twice as many permanent houses, and had finished less than half as many as private enterprise. This was not the fault of the local authorities, who were carrying a burden for which they had not been designed. Did the Government, Mr. Manningham-Buller asked, appreciate sufficiently the needs of rural areas? Between the wars something like 40,000 houses a year were built in the country, but only 3162 had been built in the rural districts while Mr. Bevan had been in office, and 3056 of these were produced by private enterprise. He warned the Minister that all his skill in rhetoric, and all his wordy vehemence would not save him from the wrath of the people who, but for his policy, might have been enjoying better housing conditions this winter.

Mr. A. Bevan, Minister of Health, claimed that the Government's decision last year to place the principal responsibility for the provision of houses upon the local authorities had been justified. By the end of August they had handed over to the building industry the job of building 155,000 permanent houses, excluding 54,000 licences given for houses for sale. He would continue to insist that houses should be built to let, and that the local authorities should be the only instrument for carrying out the housing programme. The only valid criticism of his policy was that no houses at all should be built for sale. The temporary housing programme had been so devised by the Conservatives that unfortunately its completion was now competing with the permanent programme. But the supply of building materials was now marching with the number of houses put into contract by the local authorities. One of the reasons for the slower rate of the permanent programme was the very success of the local authorities, who had put a higher number of houses into contract than the industry were able to handle, and therefore a comparatively small labour force was spread too thinly over a large number of houses.

Lady Megan Lloyd-George thought the number of workers still employed on bomb damage repairs disquieting compared with those engaged in building permanent houses. Above all, non-essential work must be ruthlessly cut. She appealed to the Prime Minister to establish a minister of building to coördinate the activities of the other ministries and to be responsible for building priorities. Dr. L. **COMYNS** drew attention to the serious situation in blitzed areas. In Silvertown, his own constituency in the East End of London, 16,000 families were desperately in need of accommodation. Was it any wonder, he asked, that the temper of the people was rising and that they put forward a claim for priority for their housing? He suggested that the labour shortage could be relieved in three ways—by a severe curtailment of the licences granted by local authorities and the Ministry of Works, by limiting the issue of licences by the Ministry of Works for non-essential work without regard to local needs, and by limiting the permitted registration of master builders.

Mr. C. **KEY**, parliamentary secretary to the Ministry of Health, in reply, said that talk about the failure to mobilise the private builder was beside the point, because practically all the present building was being carried out by private builders for the local authorities. In the end the four-to-one rule only operated in regard to the user of the house. In a recent circular the Ministry had urged that small builders should be brought together to build under contract for the local authorities 2 to 6, or up to 12, houses at a time. But the Government held that it was for the local authorities to decide that the houses should be provided, not for those who could afford to pay most but for those who had the greatest need. As showing the nation-wide effort of the local authorities to provide houses, Mr. Key said that whereas by March 31, 1920, out of a total of 1802 local authorities only 370 were building houses and only 715 houses had been completed, on August 31 this year of 1469 local authorities 1172 had houses built or building and had completed 6800 permanent houses. They had a further 89,584 houses under construction. Meanwhile work had been completed on the repair of 630,000 war-damaged houses, a further 89,000 had been made habitable, something like 50,000 houses had been erected, and 25,000 families had been provided with accommodation by the adaptation and conversion of houses. The labour actually employed on housing work had increased by 70% between July 31, 1945, and August 31, 1946. By the latter date the Government had provided accommodation for 200,000 families, and had under construction accommodation for another 200,000.

QUESTION TIME

Proposed Hospital Regions

Colonel M. **STODDART-SCOTT** asked the Minister of Health whether he was yet in a position to place in the library of the House a map showing the hospital regions he had in mind in the National Health Service Bill and the medical schools with which they were associated.—Mr. A. **BEVAN** replied: No. If the Health Bill becomes law in its present form it would then be my duty to consult the bodies and organisations concerned and lay an order defining the hospital regions before Parliament.

Resettlement of Medical Practitioners

Sir **ERNEST GRAHAM-LITTLE** asked the Minister of Health what provision was made for the resettlement in practice of medical practitioners whose houses were mortgaged to insurance companies at the time of their call-up to the Forces and who were faced with foreclosure by the insurance companies and found themselves, on demobilisation, homeless and without means to buy another practice.—Mr. A. **BEVAN** replied: The arrangements made to assist the resettlement of medical officers discharged from the Forces do not include the provision of money for the purchase of a practice which can normally be obtained from the financial agencies with whom the medical profession are accustomed to deal. If the Health Service Bill is approved by Parliament the purchase of a practice will, when the service comes into force, no longer be necessary.

Hospital Domestic Staff

Mr. R. W. **SORENSEN** asked the Minister of Labour whether, in order to ease the shortage of hospital nurses and domestic staff, further steps would be taken to invite applications both for training in nursing and for domestic work from foreign and colonial sources, including West Africa.—Mr. G. **ISAACS** replied that in addition to those coming from overseas under existing schemes, a thousand women selected from displaced persons now in the British Zone of Germany would shortly be arriving in this country for domestic work in T.B. hospitals. The extension of this scheme to include st nurses and also domestic workers for other types of h was under consideration.

M.R.C. Staff

Replying to a question, Mr. **HERBERT MORRISON** said t the salaries paid to the staff of the Medical Research Cou were as follows:

	Numbers	*Salar* £
Administrative officers	10	590–2
Scientific staff, including qualified assistants	204	300–2
Other staff paid monthly	171	250–7
Established staff paid weekly	63	Under
Temporary staff paid weekly (mainly under age 21)	96	Under

In addition, there are 15 scientific officers and 8 tempora staff paid weekly employed on a part-time basis, with salar pro rata within the ranges given above. The staff of t council were free to join trade unions and participate in un activities, as were civil servants.

What We Eat

Mr. **EDWARD EVANS** asked the Minister of Food how overall consumption of food in the United Kingdom September, 1946, compared with the consumption in Ju 1939; in how many main items the consumption was gre in how many it was less; and by what percentages in ea case.—Mr. **JOHN STRACHEY** replied: Comparisons for as sho a period as a month are misleading, and for the overall co sumption of food my statisticians work on a six mont period. We were eating in the first half of this year on t average about 7% less calories per head per day than befo the war. For the current six months consumption appe to be running at a rate of 2920 calories per head per day compared with 3000 before the war; thus our overall consum tion may be shown, when we get the final figures, to be no only some 3% below pre-war. But of course these averag conceal the fact that some people are eating much less, a other people much more, food than they did before the w The following figures from the *Statistical Digest* (Augu 1946) compare the actual amounts of those foods which we *out of our hands and into those of the public in* the thr *months' period, June, July, and* August of this year, wi the consumption of those foods on an average for the ye 1934–38.

In fats, butter, margarine, cooking fat, and the like, taken togeth we are each of us on the average eating about 4 oz. for every 5 o we ate before the war.

We are getting 9 oz. of tea for every 10 oz. we drank befo the war.

We are only getting just over half as many shell eggs per head we did before the war, and the same is true of bacon and ham.

Taking fresh and tinned meat together, we are eating alm exactly as much, on the average per head, as we did before the w

On the other hand we are eating:

Nearly 3 lb. of fish for every 2 lb. of it we ate before the w

Even after bread-rationing we are still eating just a lit more bread, cakes, &c., than before the war.

We are eating 5 pots of jam or marmalade for every 4 p that we ate before the war and, last but not least, we drinking very nearly half as much milk again, 47% more, th before the war.

The House must not suppose that in giving these figu I am denying the existence of a food shortage. On the contra there is still a food shortage just as there was before the w But now because of the great increase in working-class pu chasing power everybody has much nearer a fair share.

Milk-production

Replying to a question, Mr. T. **WILLIAMS** stated that estimated total quantity of milk produced, including mi fed to livestock, in England and Wales in the year end May 31, 1946, was 1402 million gallons, and that for 1945– was provisionally estimated at 1444 million gallons. T corresponding figure for 1938–39 was 1463 million gallons.

Supplies of Penicillin

Sir **JOHN MELLOR** asked the Minister of Supply whether was satisfied that sufficient penicillin was now available f United Kingdom requirements; and whether he wou revoke the Control of Penicillin Order, 1946.—Mr. Jon **WILMOT**: Although the supply position has improved co siderably, the removal of control measures would not justified at present. The scope of the order is, howeve being extended, as from Nov. 1 next, to allow registere veterinary surgeons to acquire supplies of penicillin.—Sir Jon **MELLOR**: Are we not now exporting penicillin?—Mr. **WILMOT** Yes.

Bovine Tuberculosis

ieut.-Colonel G. M. **SHARP** asked the Minister of Agriculture ther the months of delay in the identification of a tuberıus cow in a herd suspected of having caused bovine erculosis was due to unavoidable technical reasons; and ether he would exercise his powers under the Food and ıgs (Adulteration) Act, 1938, and order immediate pasteuriion of the milk from that herd.—Mr. T. **WILLIAMS** replied ıt where tubercle bacilli were found in a bulk sample of milk ken in a consuming area, the offending cow, if still in the rd, was usually detected quickly, but in a small minority cases there might be some unavoidable delay, due to the ed for biological tests. The point raised in the latter part of e question was, however, under consideration by the partments concerned in connexion with the revision of the ılk and Dairies regulations.

Care of Children

Mr. **WILSON HARRIS** asked the Minister of Health whether is attention had been drawn to the strictures passed in the eport of the Curtis Committee on the treatment of children n many public-assistance institutions; by what local or entral authority these institutions were inspected; whether here had, in fact, been regular inspection; and whether e facts cited were known by his department.—Mr. **BEVAN** replied: These institutions are supervised by county and county-borough councils and inspected by my inspectors. During the war the frequency of inspections had to be reduced and many of the defects found could not be easily remedied, but my department and the authorities did their best under war-time conditions to maintain a proper standard.

Mr. **WILSON HARRIS**: I am sure the Minister feels as strongly about this as anyone could but does he mean that the revolting conditions disclosed in this report could go on existing without anyone in a position to alter them knowing about them; if so, can he give the House a definite assurance that any steps taken under this report will provide absolute safeguards against any child being subject to these conditions in future?—Mr. **BEVAN**: The hon. member and the House generally will probably have an opportunity of considering the whole matter and they will then be able to satisfy themselves whether our proposals are sufficient to prevent a recurrence of these unhappy incidents. But I hope hon. members will not convey the impression that this state of affairs is universal, otherwise we should lose very many of the devoted workers who are at the moment feeling that they have been tainted by the general atmosphere.

Mrs. **LEAH MANNING**: In view of the last remark would it not be a good thing if the Minister published the names of those institutions against which the worst of these strictures have been made and which have given rise to the greatest public indignation?—Mr. **BEVAN**: I would like notice of that question, but I must point out that there are some difficulties connected with it. If evidence given to a Crown inquiry is to be published in this way it might stop such evidence ever being collected in future.—Mrs. **AYRTON GOULD**: Is anything being done to put a stop to bad conditions, where it has been proved that they exist, pending the statement to be made in the House?—Mr. **BEVAN**: Certainly; inspection is now proceeding more vigorously and efficiently than ever before and greater protection is given to these children.

B.C.G. Vaccine

Dr. S. **SEGAL** asked the Minister of Health to what extent supplies of B.C.G. vaccine for tuberculosis were now available in this country; and how they might be obtained.—Mr. **BEVAN** replied: B.C.G., which is used in various countries for the prevention (not the treatment) of tuberculosis, is not at present available here. Steps are being taken, however, with a view to securing its manufacture in this country.—Dr. **SEGAL**: Is it not time the Minister appointed a commission of inquiry into the relative merits of this and other vaccines for the prevention of tuberculosis among contacts?—Mr. **BEVAN**: The situation in this field fortunately changes almost from week to week, and it is indeed doubtful whether a commission of inquiry would be in a sufficiently static position to make its recommendations of any value.

Tuberculosis in Vienna

Replying to a question, Mr. J. **HYND** stated that there were 491 new cases of tuberculosis in Vienna in April, 481 in May, 658 in June, 369 in July, 382 in August, and 335 in September. The number of beds at present available for these cases in Vienna was 2500.

Obituary

T. WARDROP GRIFFITH

C.M.G., M.D., LL.D. ABERD., D.SC., F.R.C.P.

Dr. T. Wardrop Griffith, emeritus professor of medicine in the University of Leeds, died at his home in Leeds on Oct. 21, at the age of 85.

Born in Aberdeen, he was educated at the grammar school and the university there. A year after qualifying, with highest honours, in 1882, he went to Leeds, where he was to spend the rest of his life. After holding an appointment as resident medical officer at the General Infirmary, he turned his attentions to anatomy, and in 1887 was elected to the chair. The next year he took his M.D., again with highest honours. He became M.R.C.P. in 1901, and F.R.C.P. in 1908. He had wide interests, for he held appointments also as honorary physician and honorary pathologist to the General Infirmary; and in 1910 he surrendered the chair of anatomy to take that of medicine, which he retained until his retirement in 1925. His main interest was cardiology; and his Schorstein lecture of 1912 was devoted to Cardiac Problems.

J.P. Studio, Leeds

During the first world war he served, as a major and later lieut.-colonel, with no. 2 Northern General Hospital at Beckett's Park, Leeds; and in 1918 he was appointed C.M.G. From 1918 to 1927 he represented the University of Leeds on the General Medical Council. He was also honorary cardiac consultant in Yorkshire to the Ministry of Pensions, honorary consulting physician to the Leeds Public Dispensary, and consulting physician to St. James's Hospital. In 1922 his own university honoured him with the degree of LL.D., and in 1929 he received the honorary degree of D.SC. from the University of Leeds. From 1924 to 1926 he served on the council of the Royal College of Physicians.

The Leeds School of Medicine owes much to Wardrop Griffith. His teaching in the outpatient department and the wards, coupled with his devoted care for patients and his never-failing punctuality were a source of inspiration to the students of his day; and he gained the affection and regard of all who came into contact with him.

His wife, formerly Miss Louise Talbot, of Leeds, died in 1937. Two sons survive him, one of whom is headmaster of Oakham School.

Public Health

Paratyphoid Fever in Sheffield

THE outbreak of paratyphoid fever reported in Sheffield is due to Vi-bacteriophage type 2. Admissions to hospitals continue, and 94 cases were confirmed or suspected up to Oct. 28. The outbreak is peculiar in that the attack-rate is heaviest in children under 10 years of age and the maximum incidence appears to be in the 1–5 year age-group. At these ages the disease is of moderate severity. The more usual aliments have been excluded, but the vehicle of infection remains undetermined. The outbreak appears to be confined to Sheffield, but doctors in surrounding districts should be prepared to encounter cases of paratyphoid fever. By bringing suspicious illness to the notice of health departments promptly they may help the investigations.

Infectious Disease in England and Wales

WEEK ENDED OCT. 19

Notifications.—Smallpox, 0; scarlet fever, 1048; whooping-cough, 1375; diphtheria, 278; paratyphoid, 22; typhoid, 5; measles (excluding rubella), 2385; pneumonia (primary or influenzal), 407; cerebrospinal fever, 30; poliomyelitis, 20; polio-encephalitis, 1; encephalitis lethargica, 1; dysentery, 57; puerperal pyrexia, 134; ophthalmia neonatorum, 72. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals *of the London County Council on Oct. 16 was 835.* During the previous week the following cases were admitted: scarlet fever, 66; diphtheria, 25; measles, 21; whooping-cough, 20.

Deaths.—In 126 great towns there were 1 (0) from enteric fever, 1 (0) from measles, 1 (0) from scarlet fever, 11 (1) from whooping-cough, 1 (0) from diphtheria, 48 (0) from diarrhœa and enteritis under two years, and 8 (2) from influenza. The figures in parentheses are those for London itself.

Rhondda reported the fatal case of an enteric fever. There were 8 deaths from diarrhœa and enteritis at Liverpool.

The number of stillbirths notified during the week was 295 (corresponding to a rate of 33 per thousand total births), including 28 in London.

Appointments

EUSTACE, A., M.B. N.U.I., D.P.H.: medical officer of health and school medical officer, Accrington.

GEFFEN, D. H., M.D. Lond., D.P.H.: medical officer of health, borough of St. Pancras.

LLOYD, N. L., M.B. Lond., M.R.C.P.: chief medical officer, Ministry of Supply.

LOVELOCK, J. E., B.M. Oxfd, M.R.C.P.: physician i/c department of physical medicine, Hospital for Consumption and Diseases of the Chest, Brompton.

MCLARTY, I. J., M.B. Edin.: assistant medical officer for maternity and child welfare, Sheffield.

MOORE, E. H., M.B. Lpool, D.P.H.: deputy medical officer of health, Accrington.

PATERSON, A., M.D. Edin., M.R.C.P.: physician, Maudsley Hospital, London.

ROTH, M., M.B. Lond., M.R.C.P.: senior registrar, Maudsley Hospital, London.

STOKES, J. F., M.B. Camb., M.R.C.P.: assistant physician, University College Hospital, London.

WHITE, D. N., M.B. Camb., M.R.C.P.: senior registrar, Maudsley Hospital, London.

Chelsea Hospital for Women:

EVANS, A. B., M.B. Camb., F.R.C.S., M.R.C.O.G.: surgeon to outpatients.

JACKSON, I. M., M.B. Camb., F.R.C.S., M.R.C.O.G.: chief assistant.

LEWIS, T. L. T., M.B. Camb., F.R.C.S.: chief assistant.

RICKFORD, R. B. K., M.D. Lond., F.R.C.S., M.R.C.O.G.: chief assistant.

STEEL, G. C., M.R.C.S., D.A.: anæsthetist.

WOODFIELD-DAVIES, H., L.M.S.S.A., D.A.: anæsthetist.

WYNN-WILLIAMS, G., M.B. Lond., F.R.C.S., M.R.C.O.G.: chief assistant.

Births, Marriages, and Deaths

BIRTHS

HEMPHILL.—On Oct. 23, in London, the wife of Dr. Peter Hemphill—a daughter.

KREMER.—On Oct. 21, in London, the wife of Dr. Michael Kremer—a son.

MISKIN.—On Oct. 22, at Hove, the wife of Dr. G. W. Miskin—a daughter.

MOSS-BLUNDELL.—On Oct. 25, at Moreton-in-Marsh, the wife of Major A. J. Moss-Blundell, R.A.M.C.—a son.

PUGH.—On Oct. 19, at Hitchin, the wife of Dr. Griffith Pugh—a daughter.

RIDDOCH.—On Oct. 22, in London, the wife of Mr. Keith Riddoch, F.R.C.S.E.—a son.

SANDERSON.—On Oct. 20, the wife of Dr. G. H. Sanderson, of Horncastle—a daughter.

SCHOLEFIELD.—On Oct. 18, at Chiswick, the wife of Mr. John Scholefield, F.R.C.S.—a daughter.

TURNER.—On Oct. 21, at Maidenhead, the wife of Dr. Donald Turner—a daughter.

WELBON.—On Oct. 21, at Ipswich, the wife of Dr. J. W. S. Welbon—a daughter.

DEATHS

BURRELL.—On Oct. 22, at Fareham, Arthur William Burrell, M.D. Lond., M.R.C.S., aged 84.

DRYBROUGH-SMITH.—On Oct. 19, at St. Leonards-on-Sea, Ernald Drybrough-Smith, M.D. Edin., F.R.C.S.E., aged 64.

ELLIOT.—On Sept. 7, at Shoal Bay, New South Wales, Henry Pritchard Elliot, M.B. Edin., aged 75.

FELIX-JONES.—On Oct. 21, at Bournemouth, Frederick Felix-Jones, M.R.C.S., D.P.H., aged 90.

GRIFFITH.—On Oct. 21, at Leeds, Thomas Wardrop Griffith, C.M.G., M.D., LL.D. Aberd., D.SC. Leeds, F.R.C.P., emeritus professor in the University of Leeds, aged 85.

JACKSON.—On Oct. 21, at Worthing, Brevet-Colonel George Scott Jackson, C.B.E., D.S.O., T.D., M.D. Glasg.

LEDWARD.—On Oct. 19, Hugh Davenport Ledward, M.A., M.B. Camb., late of Broadway, Letchworth, Herts, aged 68.

MACDONALD.—On Oct. 26, at Barnton, Midlothian, William Kelman Macdonald, M.D. Edin.

MALLAM.—On Oct. 24, at Oxford, Ernest Mallam, D.M. Oxfd.

PEACOCK.—On Oct. 22, at Ipswich, William Henry Peacock, C.B.E., M.B. Durh.

TROUP.—On Oct. 24, at Inveresslie, Aberdeenshire, George Alexander Troup, T.D., M.D. Aberd., D.P.H.

VIRET.—On Oct. 23, Wilfrid Foster Viret, D.S.O., M.R.C.S., aged 36.

Notes and News

MORE NURSES

THE demands which nursing is going to make on the woman-power of the country can no longer be met from the yearly quota of girls who obtain the school certificate, and Sir Ernest Rock Carling, F.R.C.S., speaking at the Southend Municipal Hospital on Oct. 19, declared that examinations were anyhow a false guide to the women who were wanted. He would like to see established a two-year basic course in the art and craft of nursing, open to girls without any difficult entrance examination, to be taken by all recruits, which would at the end entitle them to the name of "nurse"—not assistant nurse. In a further course of 1½ to 2½ years for all whose education was adequate, specialisation might begin early, and these students would attain to the title of nursing-sister (surgical), (children), (obstetric), and so on. From the best of this class would be chosen those who would graduate from the staff colleges which he would like to see set up in every region or group of regions, each allied to a university. Their graduates would provide the matrons, sister-tutors, and sisters-in-charge.

Going on to speak of the future functions of these leaders of the profession, Sir Ernest suggested that the work of the matron might be divided between wardens, who would be in charge of the nurses' colleges and hostels, and administrators of high rank who would not attempt to preserve a day-to-day knowledge of all the diverse fields of technical competence. That would be left to the sisters in charge of medical and surgical units, whose status was enhanced in proportion as treatment became more technical. Indeed, Sir Ernest thought, the sister-in-charge had had a raw deal from the Rushcliffe Committee; for in his opinion hers is the supreme position in the nursing world of the future.

INDUSTRIAL HEALTH IN CROYDON

AT Croydon, which up till now has had seven or eight doctors employed on part-time factory work, an industrial medical council has been formed to provide employers with clinical and advisory services. The council is prepared to undertake the examination of employees, the treatment of factory injuries, and the training of first-aid personnel; and to advise on hygiene in the factory, prevention of sickness, observation of young workers, and food. According to the *Manchester Guardian* (Oct. 24) it is suggested that the smaller firms should organise themselves into groups of four and six, all of whose employees would be attended and advised by one doctor; and the Croydon Chamber of Commerce has agreed to assist in this arrangement. The scheme has been initiated principally by Sir Ernest Cowell, F.R.C.S., who sees the council as the prototype of a national scheme.

HEBERDEN SOCIETY'S DINNER

AT a dinner given by the society in London on Oct. 25, Dr. C. W. Buckley, the president, proposing The Future of Rheumatology, recalled that the society, now celebrating its tenth anniversary, had originated and developed almost side by side with the Empire Rheumatism Council. A new stage in the campaign was beginning, in which the disease was to be studied from its origin; the first objective must be to educate the general practitioner in the early manifestations of the disease; the general public, too, should be taught the importance of seeking prompt medical advice. Prof. L. S. P. Davidson said that central and local authorities had been slow to support the campaign because they had hitherto not been satisfied that the scientific and clinical approach were up to the required standard; indeed, physicians, including those in teaching hospitals, had run away from the problem. Now, however, the Ministry of Health and the Department of Health for Scotland were willing to help. Professor Davidson expressed his faith in a sound future service for the elucidation of the problem. Dr. W. S. C. Copeman, proposing The Guests, said that the presence of Lord Moran, P.R.C.P., indicated that the society had attained adult status. He also welcomed as a guest Lord Horder, an honorary member of the society, to whom the success of the campaign was largely due; Lord Horder had taken an active part in the campaign against rheumatism from the first, when "he found this a medical Cinderella of easy virtue." Dr. Loring T. Swaim, replying for the guests, said that since the formation of the American Rheumatism Association the general public's interest in the disease had been aroused. Moreover, in every American university udents were having a course of instruction on the disease. r. Birger Strandell said that the Swedish Medical Society ad lately established a rheumatism section; the problems n his country were similar to those in Britain.

ONCESSIONS TO NURSING CANDIDATES WITH WAR EXPERIENCE

ASSISTANT nurses who have been enrolled by virtue of two ears' whole-time nursing since the war began may be granted remission of six months in the normal three-year period of raining for State registration. This concession already applies to men and women who have had suitable nursing experience in the Forces or as members of the Civil Nursing Reserve, the British Red Cross Society, or the St. John Ambulance Brigade. Men and women with not less than two years' active nursing experience in one of the above categories will also be eligible for a remission of one year in the normal two-year period of training for the Tuberculosis Association's certificate: they may be allowed to take part I of the examination on entry to training.

Application should be made to the hospital or sanatorium where the candidate wishes to train.

THE SMOKE EVIL

IN his presidential address to the National Smoke Abatement Society at Brighton on Oct. 24, Sir GEORGE ELLISTON said that the society's policy is no longer a counsel of perfection; it has now become a matter of urgent necessity on the lowest economic grounds alone. "There is little use the Ministry of Fuel and Power and other Ministries lamenting the shortage of coal for every purpose—industrial, domestic, and export—when we scatter no less than 2½ million tons of it unburnt into the air to cause damage to our buildings and possessions, which with other costs conservative authorities have estimated at £2 million per week. . . Fantastic as it may seem, we are in effect employing 10,000 miners to produce smoke, and a far greater number of other people in clearing up and making good all the damage it does." The fight against the smoke evil, which for generations had wasted so much of the nation's health and wealth, was now, Sir George thought, entering its final and decisive stage. "The full implementation of all that is contained in the Domestic Fuel Policy Report, the provision of new kinds of legislation, and the early establishment of expanding smokeless zones—all these and other policies are practicable, and give well-defined objectives that when they are won will mean the virtual end of smoke."

A report to the conference showed that, of 200 local authorities questioned, about a quarter have considered the possibility of heating buildings from a central source, as has been done successfully on the Continent. In all parts of the country antiquated grates burning solid fuel are being fitted in new houses because of the acute shortage and high cost of modern types able to burn both soft coal and other solid fuel. One speaker said that in the ordinary domestic grate only 10% of the potential heat in the coal is usefully employed, and another recalled that more than two years ago the *Housing Manual* of 1944 urgently recommended that the new types only should be used in all new houses. "We hear with dismay that appliances of obsolete pattern are still being produced and supplied to housing authorities."

SAFETY UNDERGROUND

IT will be recalled that some weeks ago a London Transport electric train overran the buffers after the collapse and sudden death from heart-failure of the motorman. Precautions against such accidents as this fall into two groups: (1) engineering devices, such as automatic signalling and "dead man's handles"; and (2) the medical selection of motormen. We are informed that operative staff employed by the London Passenger Transport Board are carefully investigated after any lengthy illness or whenever their complaint may be associated with sudden incapacity. They are also examined at promotion and at the ages of 60, 62, and 64, and their vision is tested at the ages of 50 and 55. Regular medical examination may reveal some of the causes of sudden complete incapacity; but others, such as angina pectoris, petit mal and grand mal, narcolepsy, and congenital cerebral aneurysm may remain undetected in the absence of a preliminary complaint by the patient. Fortunately sudden illness from these causes seldom occurs without some preliminary incapacity; and experience has shown that the man's sense of responsibility prompts him to declare his symptoms.

CARE IN MILK CERTIFICATION

THE Ministry of Food is appealing to doctors to observe scrupulous accuracy in certification when patients ask for priority milk and to confine the issue of certificates to the categories sanctioned. During the late war priority allowances to invalids amounted to about 200,000 gallons a week; they now stand at 1,300,000 a week, though there is no reason to suppose that there has been a corresponding increase in invalidism.

The supply situation this winter will be such that unless a reduction to the war-time level is attained the weekly allowance to normal consumers will probably have to be reduced to below the present 2 pints. After Nov. 30 no medical certificate for priority milk dated before Nov. 3 will be valid, and the Ministry hopes that doctors will take this opportunity for recertification to explain to applicants for certificates that stricter criteria are imperative. Failing improvement it may be necessary to curtail the allowances to invalids or to reduce the number of priority categories.

CANCER EXPLAINED FOR THE LAYMAN

IN a little book[1] designed to provide the non-medical reader with factual information about the nature, diagnosis, and treatment of cancer, and to stimulate his interest in cancer research, Dr. Berenblum uses in the main non-technical and simple language. Where technical terms are unavoidable they are clearly explained and are included in a glossary. Eight pages of diagrams and photographs provide simple, well-chosen visual aids to a comprehension of the problems discussed. The frequency of cancer, the influence of heredity and environment, and the essential nature of the disease are discussed, and the author does much to dispel the prevalent but erroneous belief that, since nothing is known about cancer, one man's opinion is as good as another's. He sketches present-day methods of treatment and puts them in a favourable light, without ignoring their limitations. The exact difficulties which face those in search of an ideal curative agent are set forth candidly, which will give laymen some data on which to judge extravagant claims.

Among experts, the chapters on the nature of cancer and research would be likely to provoke some adverse comment, but it is not for the expert that they were written. The likely effect upon the layman is difficult to judge: he will certainly gain insight into the complexity of the whole problem and will realise that workers in this field have accomplished much.

University of Oxford

In a congregation on Oct. 17, the following degrees were conferred:

B.M., B.Ch.—J. G. Byrne, I. M. Shepherd, J. C. Edwards, L. H. Truelove, E. O. Field, M. S. de Mowbray, Marion C. Robinson (all in person); C. H. Kaye, E. L. Newell (in absentia).

University of Cambridge

The following degrees were conferred on Oct. 19:

M.D.—Elchon Hinden, W. B. D. Malle, H. L. Ellis.

M.B., B.Chir.—M. Q. Birkbeck, E. A. D. Boyd, Rodney Finlayson, B. O. Reed, P. F. C. Jackson, J. H. Jacobs, I. M. Ramsden (by proxy); E. L. McDonald, M. G. Cox (in person).

M.B.—J. L. Morgan (by proxy).

Messrs. Eli Lilly & Co. have undertaken to provide $3500 for research on the relation of radiation to chemotherapy. The work will be carried on in the department of radiotherapeutics, under the direction of Dr. E. Friedmann.

University of London

Dr. M. A. Rushton has been appointed to the university chair of dental medicine tenable at Guy's Hospital medical school. Dr. C. V. Harrison has been appointed to the university readership in morbid anatomy tenable at the British Postgraduate Medical School.

Royal College of Surgeons of England

A meeting of fellows and members will be held at the College, Lincoln's Inn Fields, W.C.2, on Wednesday, Nov. 13, at 5.30 P.M.

The Bradshaw lecture will be delivered on Thursday, Nov. 14, at 5 P.M., by Sir Heneage Ogilvie, who is to speak on Surgical Handicraft.

Ministry of Pensions

Prof. N. Hamilton Fairley, F.R.S., has been appointed honorary consulting physician in tropical medicine to the Ministry.

---

[1] Science versus Cancer. By I. Berenblum, M.D., M.Sc., demonstrator at the Sir William Dunn School of Pathology, Oxford. London: Sigma Books. Pp. 116. 6s.

Board of Control

The Board of Control are returning from St. Annes-on-Sea to London and from Nov. 11 their address will be 32, Rutland Gate, Knightsbridge, S.W.7. (Telephone: Kensington 3456.)

General Board of Control for Scotland

The appointment of Dr. H. B. Craigie as a medical commissioner has been announced. Dr. Craigie is at present deputy superintendent of Whittingham Mental Hospital, Preston.

Reablement in Scotland

The Fitness Centre at Gleneagles Hotel is to be transferred next year to a part of Bridge-of-Earn Hospital. Mr. Joseph Westwood, Secretary of State for Scotland, has decided that reablement shall be available to people from all types of industry, with special recognition of miners' requirements.

Demonstrations in Neurology and Psychiatry

At St. George's Hospital medical school, London, clinical demonstrations in neurology and psychiatry are to be held at 4.30 P.M. on Thursdays, by Dr. Anthony Feiling and Dr. Desmond Curran. The first demonstration will be given by Dr. Feiling on Thursday, Dec. 5.

Demonstrations of Contraceptive Technique

On Thursday, Nov. 7, at 2.30 P.M., a practical demonstration of the technique of the use of a variety of contraceptive methods will be given at the C.B.C. clinic by Mrs. Marie Stopes, D.SC. Medical practitioners may apply for tickets to the secretary, C.B.C., 108, Whitfield Street, London, W.1.

Rural Life Conference

A rural life conference has been arranged by the Church Missionary Society, to be held at High Leigh, Hoddesdon, Herts, from Jan. 7 to 10, 1947. The aim is to further the study of man in relation to his environment. Applications should be directed to the acting secretary, Rural Life Conference, C.M. House, 6, Salisbury Square, London, E.C.4.

Prize for Work on X Rays

The Royal Society of Edinburgh will award in 1947 a David Anderson-Berry medal, together with a sum of about £100, for the best recent work on the therapeutic effect of X rays on human diseases. The last date for applications, which may be based on published and unpublished work, has been postponed to Jan. 31, 1947. Entries should be addressed to the general secretary of the society, 22, George Street, Edinburgh, 2.

Ministry of Health

Dr. G. A. Clark, late professor of physiology and dean of the medical faculty at Sheffield University, has been appointed to the whole-time staff of the Ministry of Health as a principal medical officer.

On the retirement of Dr. R. E. Whitting at the end of August, Dr. C. F. Good became principal medical officer (insurance service). Dr. W. D. Hopkins is now a principal medical officer and Dr. L. M. Ladell and Dr. A. R. Doyle are senior medical officers (insurance service). Dr. E. Martin has retired.

Our annotation on staff organisation in the Ministry (1946, i. 932) should have included the name of Dr. Percy Stocks (General Register Office) as a senior medical officer.

Electroencephalographic Society

The standardisation and interpretation of results was discussed at the society's autumn meeting at the Maudsley and Runwell hospitals on Oct. 4 and 5, when a number of European workers attended. "If we are to attempt to bring electroencephalography to an exact science," said Prof. E. D. Adrian, F.R.S., the president, "it is essential that we formulate common standards and common terms which will form the basis of an international E.E.G. language." The society's primary object is the exchange of information on the science and practice of electroencephalography. It also aims to maintain a high standard in technique and the interpretation of records; to this end it has issued recommendations on the criteria of abnormal records and on the performance of E.E.G. apparatus. It is intended that membership shall be accepted throughout the world as implying a high standard in technique and interpretation. The society is willing to advise any centre or institution. The hon. secretary is Mr. G. Parr, 68, Compton Road, London, N.21.

Causes of Death

The Minister of Health has appointed the following med committee to advise the Government on the forthcom revision of the international list of causes of death:

Sir Ernest Rock Carling, F.R.C.S. (chairman), Dr. C. F. Br Prof. A. J. Lewis, F.R.C.P., Dr. A. H. T. Robb-Smith, Mr. Ear Holland, F.R.C.O.G., Prof. N. Hamilton Fairley, F.R.C.P., Prof. A. Bradford Hill, D.SC., Dr. Percy Stocks, Dr. Mel Mackenzie, Prof. Sydney Smith, M.D., Prof. W. W. D. Thomson,

The present classification of causes of death, first adop by the International Institute of Statistics in 1893, has be revised five times. The next revision, due to be made in 19 and the establishment of an international nomenclature diseases are to be carried out under the auspices of the Wo Health Organisation.

Return to Practice

The Central Medical War Committee announces th the following have resumed civilian practice:

Dr. R. H. DOBBS, 135, Harley Street, London, W.1.

Mr. CHARLES DONALD, F.R.C.S., 66, Harley Street, London W.1 (Langham 2878).

Mr. D. LL. GRIFFITHS, M.B.E., F.R.C.S., 14, St. John Str Manchester, 3 (Blackfriars 9598).

The laboratory chemicals section of the British Drug House Ltd. has been transferred to new works at Poole, in Do leaving more space at Graham Street and Wharf Road London, N.1, for the pharmaceutical and medical side of their work. Inquiries for this section should now be addressed to the B.D.H. Laboratory Chemicals Group, Poole, Dorset. (Tel.: Poole 962.) Mr. Frank Hartle, PH.D., F.R.I.C., secretary of the Therapeutic Research Corporation of Great Britain Ltd., has been appoint manager of the scientific services department of the Br Drug Houses Ltd.

Fifty Indian probationary nurses are to be trained in Sydney metropolitan hospitals. Hospitals in other State capitals may train a further 60 nurses, most of whom will go to Melbourne.

Diary of the Week

NOV. 3 TO 9

Monday, 4th

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fi W.C.2
5 P.M. Mr. Terence Millin: Surgery of the Prostate.

Tuesday, 5th

CHILBLAINS IN SERVICEWOMEN

ALBERTINE L. WINNER
O.B.E., M.D. Lond., M.R.C.P.
LATE LIEUT.-COLONEL R.A.M.C.: HON. MEDICAL CONSULTANT FOR WOMEN'S SERVICES IN THE ARMY

E. S. COOPER-WILLIS
M.A. Camb.
LATE CAPTAIN ARMY GENERAL LIST

IN the winter of 1942 the Auxiliary Territorial Service (A.T.S.) authorities began to receive reports that chilblains were causing a serious loss of efficiency among their personnel; so they asked the medical department of the War Office for help.

It seemed necessary to obtain first some accurate information on the incidence of chilblains, the amount of disablement caused, and the effect of service and employment. An inquiry was carried out by means of a questionary, which was answered by a carefully planned sample of the A.T.S. This questionary was framed by one of us (A. L. W.) with some help from experts, but not, as it transpired, enough. The replies were a sad warning of the dangers of unskilled surveys—questions were misunderstood and stupidly answered, and even when the form was correctly completed the results were impossible to code and compute with certainty. The only thing we got out of this survey was a remarkable list of the remedies which had been found to benefit the sufferers.

This questionary was therefore scrapped and another prepared, this time in conjunction with Major B. B. Swann and E. S. C.-W., both statisticians. The second questionary was issued in the autumn of 1943. It was distributed by the statistical officers at Command Headquarters at home, in close coöperation with the medical and A.T.S. authorities there, and it reached a sample of over 3000 Servicewomen, who completed the form, whenever possible, in the presence of an officer, who dealt with questions about the form and tried to ensure that it was correctly answered. The completed forms * were examined to remove obvious inconsistencies and mistakes, and the remaining forms were sorted and tabulated by Hollerith machinery. The answers to 3003 questionaries were analysed. It was found that the age-distribution of the sample was that of the A.T.S. as a whole, though it had been deliberately selected in that it contained specified numbers of girls in the main jobs.

In assessing the results that follow it should be remembered that the population at risk consisted mainly of healthy young women under 40 (those over 40 were a tiny proportion). Information was not sought from women over 40 or from men. There is, however, a general (but not scientifically proved) impression that male troops have a much lower incidence of chilblains.

Results

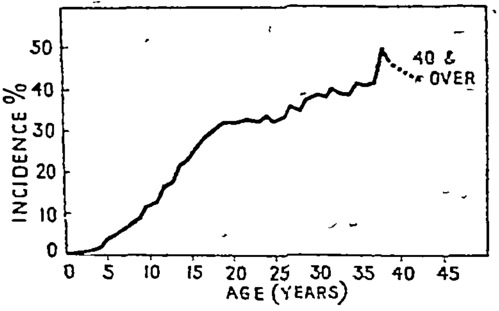
INCIDENCE

We obtained incidence-rates for chilblains at different ages by studying the histories of the girls as given in their replies. We could thus relate the number of girls who said they had started but not yet stopped chilblains at a given age, say 25, to the number of girls who had reached or passed 25 years. This method had two advantages over the more obvious one of relating those at each age who still suffered to the numbers in the sample at each age. First, it enabled us to get incidence-rates for the earlier ages before girls join the A.T.S.; secondly, the incidence-rates obtained are based on larger numbers of cases than those of the simpler method, and hence in that respect are statistically more reliable.

As the figure shows, the incidence of chilblains, as estimated, is much influenced by age. It rises steadily up to the age of 40 or so—in fact, over the whole range of ages for which our sample gives reliable results.

Applying these incidence-rates to the whole A.T.S., we estimated that at the end of 1943 about a third of the women had chilblains in winter and perhaps another sixth had had chilblains at some time in their lives. Thus, of this sample of healthy young women, at least half will have had chilblains before they are 40. The figure of a third agrees fairly well with an estimated incidence of 30% found by the cruder method of relating those who said they suffered in winter to the total of the sample. It seems doubtful how far the rates found among the A.T.S. can be applied to the civil population, especially in peace-time. We cannot say whether A.T.S. service has specifically influenced liability to chilblains, but there is reason to think that the war years have seen an increase in their prevalence. The percentage chances of starting and of stopping chilblains at each age, computed in an analogous manner to that described above for incidence-rates, showed that the chances of starting chilblains are greatest between the ages of 15 and 16, and the chances of stopping them greatest at 20.

Below are shown the results of subdividing our data into two parts, and calculating the chances of starting chilblains, based on the girls' histories up to October, 1939, and similar figures based on the four war years October, 1939, to October, 1943. The rates suggest a considerable increase in the chances of starting chilblains from the age of 18 years onwards during the war period. This increase is not related to war service but to the war years, and starts in the winter of 1939–40, before many had joined up. This confirms the French reports cited below.



Incidence of chilblains from childhood to middle-age, calculated from the replies to a questionary among A.T.S. personnel.

Age (yr.)		*Chance (%) of starting chilblains in one year, estimated from experience—* *(a) Before Oct., 1939*		*(b) Oct., 1939–Oct., 1943*
14 and 15	..	3·5	..	3·6
16 and 17	..	3·2	..	3·3
18 and 19	..	2·0	..	2·7
20 and 21	..	1·2	..	2·6
22–25 ..	..	1·0	..	2·2
26 onwards	..	1·0	..	1·6

LOSS OF EFFICIENCY

Of the 910 girls who had chilblains, 290 (i.e., 32% of them, and 10% of the whole sample) said that their chilblains hindered them in their normal activities, and 213 of these said that their chilblains had sometimes prevented their carrying out certain normal activities.

Normal activity	*Percentage of those who had chilblains*	*Percentage of whole sample*
Dressing and undressing	1	..
Carrying on normal work	6	2
Walking	17	5
Playing games	13	4

These figures, being based on the sufferers' own replies, are unlikely to err on the side of understatement. Hence we may conclude that the amount of serious incapacity and actual interruption of work caused by chilblains was negligible from the Army's point of view. The loss to the sufferer's efficiency, when it fell short of complete incapacity, cannot be estimated from this inquiry.

---

* Copies of this form, and of two other appendices, will be sent to readers who require them. Application should be made, in writing, to the Editor of THE LANCET, 7, Adam Street, Adelphi, London, W.C.2.

INTERVALS FREE FROM CHILBLAINS

We asked whether, and between what ages, sufferers had enjoyed periods of respite from the complaint, but the question was unfortunately misunderstood by many of the girls. As a result we cannot calculate the absolute frequency of such intervals. We can, however, examine their relative frequency at different ages, and this suggests that temporary freedom from chilblains is commonest between the ages of 25 and 30.

FREQUENCY OF CHILBLAINS AMONG RELATIONS OF SUFFERERS

Girls who had chilblains said more often than did girls who did not have chilblains that one or more near relations had also suffered. The differences in the figures given below are suggestive but need not necessarily be interpreted as meaning that there was really an incidence among the relations of sufferers higher than that among the relations of girls who had no chilblains; for sufferers are likely to be more interested in the chilblains of their relations, or else to be informed of them by way of consolation. It is noteworthy that the highest stated incidence—that among brothers and sisters of girls who still suffered—was not much higher than that estimated for the A.T.S. as a whole.

	1646 girls who had never had chilblains	*447 who no longer had chilblains*	*910 who still had chilblains*
A parent suffered ..	4%	10%	20%
A brother or sister suffered	12%	26%	34%
An aunt, uncle, or cousin suffered ..	2%	4%	5%
No near relation suffered	84%	65%	50%

The percentages total more than 100 because some girls said that more than one relation had chilblains.

INFLUENCE OF A.T.S. OCCUPATION ON CHILBLAINS

There is evidence of a definite association between being in certain A.T.S. occupations and having chilblains. The results we found may be summarised as follows (they are discussed in more detail below):

(1) Office workers—i.e., officers and clerks—appear to have been more liable to chilblains than those in other occupations.

(2) Cooking appears to affect chilblains favourably.

(3) Office workers get chilblains more often on their hands and less often on their legs, feet, and ankles than do other girls.

(4) The reverse is true of cooks and other indoor non-sedentary workers—i.e., storewomen, postal workers, and anti-aircraft plotters—whose chilblains are more common on the legs, feet, and ankles, and less so on the hands, than are those of other girls.

(5) There was no evidence that exposure—i.e., in outdoor occupations, such as anti aircraft operational employments—had any effect one way or the other. The only exception is searchlight personnel, possibly the most exposed of all, where the incidence is significantly reduced.

Incidence.—Out of some 21 trades † the actual incidence of chilblains in our sample is above the average—i.e., 30%—among officers, clerks, and drivers of motor vehicles, whereas it is below the average in cooks, teleprinter operators, and searchlight personnel:

	No. of cases
Officers	109 (66%)
Clerks	412 (38%)
Drivers of motor vehicles.. ..	141 (43%)
Cooks	345 (17%)
Teleprinter operators	132 (15%)
Searchlight personnel	100 (16%)

These differences are the only ones we judge to be statistically significant.

The above results should not be too readily accepte as evidence of the influence of occupation on incidence, nor can these percentages be taken as reliable estimat for the A.T.S. as a whole. The samples of each trade ar small and had mostly to be selected from a few units f reasons of economy. Hence we cannot tell whethe the girls are really representative of their trades. We can, however, obtain additional evidence from the answe to the question on how service in the A.T.S. has affecte chilblains. The answers for the 1357 girls who had some period suffered from chilblains were as follows:

No change or no answer	52%
Stopped or better since joining A.T.S.	28%
Started or worse since joining A.T.S. ..	20%

In the absence of any way of telling what would ha happened to these girls if they had not joined the A.T.S we cannot evaluate the effect of A.T.S. service on t whole group. We can, however, compare the relati frequencies of favourable and unfavourable effects on gir in the various trades. We find that officers and clerk have been affected for the worse and cooks for the bett by their service:

	Better	*Worse*	*No of cases*
Officers	14%	42%	83
Clerks	23%	29%	207
Cooks	37%	8%	118

These are the only differences we can accept as statistical significant. We did not examine in detail how far the differences between trades might be due to difference in the ages of the girls in the sample. At the date of th survey over three-quarters of the A.T.S. were between 1 and 26 years old, ages over which the incidence of chil blains did not seem to change much.‡ The largest age differential was expected to be between officers and othe ranks. Correction of the rate for officers for this differenc would only mean a reduction of about 10% in it. More over, the question of the effect of A.T.S. service on chil blains should be very much less affected by age-differen tials than the crude incidence of figures, as the chances o starting and of stopping chilblains are nearly equal ove the relevant range of ages. Hence, where the two tests lead to similar results, we feel fairly confident that age-differences cannot explain the observations.

Sites.—Among the 910 girls who still had chilblains the percentage frequencies of the various sites were as follows:

Feet	48%
Hands	28%
Ankles	13%
Legs	9%
Ears	1%
Other places and no reply ..	1%

We find the following outstanding differences from th above between office workers and indoor non-sedentar workers:

	Officers and clerks	*Cooks, storewomen, plotters, and postal workers*
Hands	34%	19%
Feet, ankles, legs	65%	78%
Elsewhere, &c. ..	1%	3%

EFFECTS OF MENSTRUATION

The monthly period did not make any difference t the chilblains of the 1357 who had ever had them, 1 thought their chilblains were better and 1% worse durin menstruation.

CONDITIONS AGGRAVATING CHILBLAINS

We asked in the questionary whether any of the lis of conditions or circumstances aggravated a girl' chilblains. The percentage frequency of the answers i given below, based on the 910 who still suffer. There did not appear to be any significant difference between trades.

---

† Set out in appendix II (obtainable on written application to the Editor).

‡ Data on the effect of age on chilblains are set out in appendix II (obtainable on written application to the Editor).

Hot-water bottles and sitting by the fire ..	24%
Cold dry weather	19%
Cold damp weather	19%
Tight shoes or gloves	9%
Protracted standing	8%
Exposure to draughts	6%
Being out of doors	6%
Keeping hands wet	5%
Changing from battle dress to Service dress	2%
Unclassified	2%

REASONS FOR CHILBLAINS STOPPING

The reasons given by those who no longer suffered for the cessation of their chilblains did not suggest that in many cases the usual remedies and treatments were found very effective if sought. In more than half the cases the girls did not know why their chilblains stopped, and in only about 26% were the cures ascribed to home remedies or doctors' treatment.

Don't know and no answer	55%
Home remedy or doctors' treatment ..	26%
Change of occupation or moving to another part of the country	19%

TREATMENT USED

The first questionary asked "What have you done for your chilblains that makes them better?" and the replies provided an interesting sample of folk medicine, magic, medical fashion, and the results of patent-medicine advertising. There are 78 remedies suggested, and we list them below as a revelation of the resource and variety which results from the absence of any specific well-authenticated remedy:

Ointments

Zinc ointment
Sulphur ointment
Wintergreen ointment
'Mentholatum' ointment
'Iodex'
Lanolin
Herbalist's ointment
'Snowfire'
'Grasshopper' ointment
'Germoline'
'Zambuk'
'Diamond Chil Cure'
'Nulrose'
'Chilipaste'
'Panacell'
'Zeekol'
'Mystic'
'Lazarus'
'Itsit'

Lotions

Methylated spirits
Surgical spirit
Tincture of iodine
Hydrogen peroxide
Pot. permanganate
Tinct. benzoin co.
Menthol in surg. spirit (14·5%)
Spirits of camphor
Chalk and vinegar
'Sloan's liniment'
'T.C.P.'
'Vick liniment'
'Dettol'
'Milton'
'Cadum'
'Ayrton Saunders C.C.'

Other local applications

Whisky
Lard
'Radox'
Cajuput oil
Castor oil
Camphorated oil
Snow
Turpentine and mustard
'Elastoplast'
'Camphor ice'
Ammonia and opheldeldox
'Antiphlogistine'
Ichthyol
Raw potato
Roasted onion
Onion dipped in paraffin
Paraffin
Urine §

Internal remedies

Halibut-liver oil
'Adexolin'
Calcium
'Calsimil'
Colloidal iodine
Vitamin C
Hay tea
'T.C.P.'

General applications

Hot and cold bathing
Salt-water baths
Mustard baths
Hot water
Ultraviolet light

Other treatments

Eating green vegetables
Eating cheese
Drinking milk
Exercise
Extra clothes
No artificial heat
Woollen coverings
Crêpe soles
Boots
Insoles
Fresh air
Chamois leather

Survey of Literature

The literature of chilblains is enormous and on the whole very unsatisfactory. There are a few classical papers which are really valuable and a great mass of contributions advocating a specific treatment with ætiology adapted to conform with the alleged results. The literature has not been summarised for sixteen years. The best general descriptions are those of Klingmüller and Dittrich (1926–27), Dittrich (1929a), Haxthausen (1930) with very full bibliography, and Buerger (1937). Dubreuilh and Petges (1911) are the main source for rare types and sites.

The first accurate pathological description and the first clear differentiation from frostbite were made by Hodara (1896), but the most important modern histological studies are those of Klingmüller and Dittrich (1926–27) and Dittrich (1929a), who concluded that the essential lesion was an inflammation of the smallest arterioles and capillaries, with hyperkeratosis, thrombosis of the minute vessels, and œdema; they grouped together, under the term "perniosis," ordinary chilblains, cutis marmorata, perniosis folliculata, and erythrocyanosis frigidus. This last condition, seen on the legs (especially of women), has a large literature of its own and is outside the scope of this paper, but most modern writers agree that it is similar to, if not identical with, chilblains.

The main ætiological factor is generally agreed to be cold, but Leduc, (1927) thought chilblains were first-degree burns due to incautious exposure to heat after chilling. An interesting development of this idea is Keining's (1940) distinction between autumn and spring chilblains: autumn chilblains developing mainly in women on hands and feet, due to cold and damp alone; winter chilblains commonest in male agricultural labourers, on the hands, and associated with cold plus the increasing radiation from the spring sun. There is, however, no unanimity about what factors predispose certain individuals to chilblains. Many Continental authorities regard them as manifestations of tuberculosis (Permin 1903, Stephani-Cherbuliez 1936 with excellent bibliography), but most workers now regard the chilblain merely as a *locus minoris resistentiæ* providing good soil for a tuberculous process—e.g. Bazin's disease (Dittrich 1929b, Jausion, Meunier, and Somia 1941). Others have sought to incriminate a dietetic or environmental factor; an "epidemic" of chilblains of abnormal severity was described in Germany during the inflationary period in 1921–22 (Katz 1922) and in France during the very cold winter of 1940–41 (Rabut 1941, Bordet 1941, Jausion, Somia, and Meunier 1941, Mouriquand et al. 1942). Specific dietary deficiencies incriminated have been vitamin P (Jausion, Somia, and Meunier 1941) and vitamin A (Mouriquand et al. 1942).

Other factors blamed have been hypogonadism (Charron 1925), pituitary dysfunction (Lereboullet 1922), focal sepsis (MacKenna 1937), and intestinal toxæmia (Robertson 1920, Savill 1926). Wright (1897) described diminished coagulability of the blood, thus providing the basis for the popular treatment with calcium; but Percival and Stewart (1924) showed that the blood-calcium level was consistently normal, and that no improvement was produced by raising it with parathyroid, and Hallam (1930) could not confirm Wright's findings concerning coagulability.

The present trend, however, is to correlate chilblains with some defect, inherent or acquired, in the peripheral circulation. Dittrich (1929a) regards the histological evidence as in accordance with this, and Hallam (1930) has drawn attention to the association with acrocyanosis. Moreover Barber (1926b) described a case in which the presence of bacterial emboli apparently conditioned the site and onset of chilblains, and Lewis (1941) points out the prevalence in limbs the seat of old poliomyelitis. There is some experimental work tending in the same direction. Ackermann (1936) sought to prove that there was a sympathetic hypotonia ; but, conversely, Brack (1940) thought he had demonstrated vasoconstriction and excessive loss of heat. Dittrich (1929a and b, 1936) and Lippert (1936) considered the essential feature was over-reaction to cold, whereas Lewis (1941) interpreted his experiments as showing a normal reaction to cold in an already abnormally cold skin. Finally Schröder (1944) demonstrated an abnormally slow response to warming in the skin of subjects disposed to chilblains.

---

§ cf. Heinz and von Noorden (1921).

A few other points in the natural history are of interest. The only estimates of general incidence we have been able to trace are those of Hallam (1931), who found that the incidence in 1000 casualty patients was 5·3%, in 1000 medical patients 9·2%, and 1000 tuberculous patients 13·2%. A high incidence in tuberculous patients has also been recorded by Permin (1903) and Stephani-Cherbuliez (1936). Stephani-Cherbuliez (1936) and Hallam (1930) also give age-distribution curves. A familial incidence is mentioned by Barber (1926a) and Watson (1941). Barber (1926b) also makes the interesting observation that sufferers from chilblains are of two distinct types : the stout phlegmatic "lymphatic" type, and the thin nervous type. A peculiar type of "senile chilblain" was described by Meneau (1897), and other rare clinical types by Dubreuilh and Petges (1911), Dubreuilh (1921), and Piechaud and Cazenave (1925). Finally there is a curious and probably highly significant geographical distribution of the literature, which is mostly British, French, German, and Swiss. The only really good American paper is that of Buerger (1937), and all other American papers we have been able to trace deal with rare reactions to cold and not at all with what we understand by chilblains.

The literature of therapy is confused and extensive, and serves only to reinforce the contention that there is no specific remedy. An attempt to review it in detail would take many pages, and it has already been adequately done, by von Noorden (1928) and Haxthausen (1930). All agree that measures to improve the general health are important and that adequate clothing is also essential. The most interesting recent contributions to treatment are the use of sympathectomy (Goldsmith 1936), previously mentioned by Dore (1928), and paravertebral sympathetic block (Simmons 1945) ; the addition of Grenz rays (Goldsmith 1936) to an already impressive armamentarium of physiotherapeutic measures, the revival of passive hyperæmia by Herxheimer (1942), originally described by Mitchell (1926), and the use of vitamins A and P, as previously described. Other recent suggestions have been histamine and bee venom (Watson 1941), fluorescein (Lefevre and Dubarry 1941), and 'Priscol,' (benzylimidazolin) (Brack 1940). All these have their warm advocates, but a scrutiny of the work published over the last forty years inspires only a scepticism and mistrust of all these alleged advances, and a conclusion that the radical and scientific remedy for chilblains has not yet been discovered.

Discussion

The results obtained in this inquiry are not as final and clear-cut as we should have liked, and some of them are not easy to evaluate. Certain clinical conclusions are, however, justified.

It appears that, if the A.T.S. can be accepted as representative of the healthy female population, at least half, at any rate under war-time conditions, will have had chilblains by the time they are 40 years old. It does not appear that these lesions are really disabling except to a very small proportion of women, and the loss of working time involved in the Army was not thought to justify the expenditure of money and man-hours which would have been required either for a scientific investigation into their cause or an elaborate trial of various remedies. The investigation was not, therefore, carried any further except for a very rough trial of one remedy discussed below. However, we are under no illusion about the discomfort, even misery, caused by chilblains which do not actually disable, and the very high incidence seems to require further research when more normal conditions prevail.

The relation to employment, though not conclusive, is suggestive. The general trend is consistent and appears to indicate that (1) office workers are more liable to chilblains than are those whose work is active ; and (2) those whose work is in offices tend to get chilblains on their hands, and those who stand most of the day get them on their feet. This seems to indicate that one factor is circulatory stasis.

The incidence in outdoor workers is certainly not above the average, except for motor drivers, whose work may keep them in one position for long hours. Cold must be a factor, for chilblains as a rule only develop in winter. On the other hand, we are informed by our American and Canadian colleagues that chilblains are almost unknown over there in spite of their bitter winters, and they attribute this to the universal practice of heating (or overheating) their rooms, cars, and trains, and wrapping up really warmly when they go out. Their statements are borne out by the lack of American and Canadian literature mentioned above. Some confirmation of this view is provided by the fact that the only sedentary workers to have a relatively low incidence are the teleprinter operators, whose delicate machines necessitate their offices being kept at a warm and constant temperature. Possibly our national dislike of centrally heated rooms may not be quite so healthy as we fondly think.

The familial factor is suggestive but nothing more, in view of the notorious fallibility of the human memory, and in view of the unobservant character of the average person. This point could only be settled by a large-scale questioning of numerous families, and would be an interesting piece of research for the family doctor who could do much to elucidate the natural history of chilblains.

The apparent increased incidence since the war is not easy to explain. It apparently started from the first winter, long before any fuel or food shortage had made itself felt ; it may be partly related to the very hard winters of 1939–40 and 1941–42, but it is interesting in view of the German findings of 1921–22 and the French reports of 1941–42 mentioned above.

The therapeutic position is wholly unsatisfactory. The fact that 78 remedies had been used, allegedly with success, seems to indicate that none is specific. The basis of most seems to be counter-irritation or the administration of calcium or of vitamin. The use of urine is a fascinating relic of ancient magic, and it would be interesting to know why the onion must be roasted or dipped in paraffin. No-one mentioned thyroid medication, which is surprising, since there is some evidence that both the obese hypothyroid and the thin anxious type are especially liable to chilblains ; indeed few of the numerous remedies mentioned in the medical literature occur in our list.

Therapeutic trials were no part of this investigation, because the difficulties of planning and controlling research on a large enough scale on a condition not found in hospitals were thought at this juncture to be cessive. But one particular ointment was given a ugh and ready trial in various parts of the country:

	Parts		Parts
henol . ..	1·0	Soft paraffin	25·0
amphor	6·0	Hard paraffin	7·5
alsam of Peru ..	2·0	Lanolin anhydrous to ..	100·0

he instructions issued with it were either (1) the affected art to be immersed in hot water at bedtime, dried care- ully, and the ointment applied; or (2) the ointment o be rubbed in night and morning. About 2600 one- unce tubes of this were issued and distributed to rdnance depots, clerical units, and operational anti- ircraft units. The reports from the medical officers vere almost uniformly favourable, many of them stating hat under the influence of the ointment chilblains were ess painful and healed rapidly, some saying that it was the best remedy they had met. We do not, however, deceive ourselves that this is more than an efficient palliative which probably acts by stimulating local circulation.

Summary

An analysis has been carried out on 3003 questionaries filled in by A.T.S. officers and auxiliaries, concerning the incidence and natural history of chilblains.

When the incidence at different ages was calculated, it was found that at least half the women would have had chilblains by the time they were 40 years old.

Actual time lost from work was very small.

The incidence rises steadily up to the age of 40. The most likely age for starting was 15–17, and for stopping 20–22 years. There was also a tendency to have a clear interval between the ages of 25 and 30 years.

There is some evidence that, in this group at least, chilblains have been more prevalent during the war years, though not during war service.

Office workers have a higher incidence than have those in active occupations.

Outdoor exposure does not appear to have any effect.

Office workers tend to get chilblains on their hands, whereas those whose work involves much standing get them on their feet.

There is some indication of familial influence on chilblains.

Very many remedies are reported as having proved beneficial, and it is concluded that none is specific.

The formula of a useful palliative ointment is given.

The published work on the subject is reviewed.

Our thanks are due to Lieutenant-General Sir Alexander Hood, Director-General, Army Medical Services, for his interest and permission to publish this paper; Brigadier R. M. B. MacKenna, consulting dermatologist to the Army, for constant help, stimulation, and advice; Captain C. M. B. Large, late R.A.M.C., who did much of the hard work in preparation and analysis; and the Command statistical officers and others who administered this survey. Last but not least we testify gratefully to the courtesy and helpfulness of the library staff of the Royal Society of Medicine.

FOOTNOTE

Our report was shown to the late Sir Thomas Lewis a few months before his death. He said that, in his opinion, the next part of the investigation should be to determine the critical temperatures and humidities of the environment associated with the onset of lesions; to inquire whether turbulence of air currents in rooms or offices affected the onset; and, more particularly, to determine the temperatures of the extremities of the subjects during the period preceding the onset of chilblains. This last question was designed to discover whether there was a common or an individual temperature below which all persons liable to chilblains would get them. It was not practicable to carry out such investigations under Service conditions, but the suggestions may be of interest to other workers.

TRAUMATIC PULMONARY ŒDEMA

TREATED WITH CONCENTRATED PLASMA

GAVIN CLELAND
M.B.E., M.B. Edin., F.R.C.S.E.
MAJOR R.A.M.C., SURGICAL SPECIALIST

PULMONARY œdema due to trauma carries a grave prognosis. It was observed not infrequently in battle casualties, and its causes included blast, petrol explosions, chest wounds, fat-embolism, and accidental over-transfusion with either blood or saline. In civilian accidents it is observed in burns due to underground explosions (in miners), in petrol explosions, in accidental inhalation of noxious gases in industry, and in accidental overtransfusion. Except in overtransfusion, accepted methods of treatment are not very successful.

In seeking to control pulmonary œdema due to blast, burns, or chest wounds in battle casualties, I brought into use intravenous concentrated plasma as an addition to the more usual therapeutic measures. The results of this method appeared so striking that I brought the method to the notice of fellow Army surgeons in Italy in February, 1945, in the hope that they would explore more widely its life-saving possibilities. Since that time I have been told by several of my colleagues of success attending the use of the method in their hands. It therefore seems that the method should be brought to general notice in the hope that it may prove as useful in pulmonary œdema due to trauma in civilian accidents as it did in battle casualties.

Pulmonary œdema is characterised by severe respiratory distress and pronounced cyanosis. Large quantities of frothy mucus are thrown up into the trachea and well up through the larynx. According to the degree of consciousness present, attempts are made by the patient to cough up the frothy mucus. Auscultation of the chest detects coarse crepitations throughout which sound very

close to the stethoscope. Danger to life lies in drowning through vast quantities of mucus in the alveoli and bronchial tree.

RATIONALE

I have observed on many occasions that concentrated plasma administered intravenously reduces œdema in second-degree burns, apparently by its direct action in raising the osmotic pressure in the capillaries. If this can be done in traumatic œdema in other parts of the body, it should be possible in pulmonary œdema due to trauma, though not in pulmonary œdema produced by circulatory failure as a terminal event or due to overtransfusion.

It is argued that, by withholding other fluids, the reduction in œdema could be maintained long enough to allow adequate local and general oxygenation to take place, with a resultant return to a nearly normal state of the lung capillaries. This would prevent any tendency for the condition to recur. In cases where pulmonary œdema had not developed but could be expected, the raised osmotic pressure would tend to prevent œdema.

The results described below appear to be compatible with the truth of this thesis.

METHOD

Many of the recognised methods of treatment for pulmonary œdema of traumatic origin are included, for it must be emphasised that concentrated plasma, intravenously administered, is an addition to them, not a replacement of them.

(1) Atropine gr. $^1/_{50}$ is administered intravenously to diminish bronchial secretion to a minimum as soon as possible. It is considered that the atropine can have no direct bearing on the pulmonary condition.

(2) So that maximal oxygenation may take place, as much of the mucus in the bronchial tree as possible must be removed. If the condition has only recently developed and consciousness has not been lost, the patient is encouraged to cough up as much of the mucus as possible. Often, however, the patient is either comatose or semicomatose. If this is so, the patient is laid supine, and the foot of the bed raised, to encourage the mucus to flow towards the larynx. A tube is passed, under direct vision, into the trachea, and the mucus is sucked out. The injection of 'Coramine' 3–5 c.cm. intravenously at this stage will often produce a temporary return of the cough reflex. This will bring still more of the mucus into the scope of the suction tube.

(3) Oxygen is given continuously by a method which ensures the maximal concentration of that gas in the nasopharynx. The B.L.B. mask has proved efficient for this, save in particularly restless and irritable patients, in whom the nasal catheter was used.

(4) The above-mentioned measures are instituted as rapidly as possible, and the administration of concentrated plasma intravenously is begun coincidentally. Originally, double-strength plasma was used (the dried equivalent of 800 c.cm. of human plasma dissolved in 400 c.cm. of sterile water). Latterly, triple-strength plasma has been used (the dried equivalent of 1200 c.cm. of human plasma dissolved in 400 c.cm. of sterile water). The plasma is administered at a rate of about 80 drops a minute, and little difficulty is experienced in maintaining the flow if slight pressure is used. A dose of 400 c.cm. is usually adequate, but occasionally up to 800 c.cm. is required.

(5) Other fluid intake should be limited, to obtain the maximal benefit from the increased protein concentration in the circulating blood.

(6) Should it be proposed to use the method in accelerating recovery from pulmonary œdema as a result of overtransfusion, an adequate venesection is a necessary preliminary to the infusion of the concentrated plasma.

ILLUSTRATIVE CASE-RECORDS

In the following cases the pulmonary œdema was due to various kinds of trauma. This shows the wide application of the method.

CASE 1.—An officer was admitted to a C.C.S. with widespread burns due to a petrol explosion. His general condition was good, but standard-strength plasma was administered by slow drip, because a great quantity of fluid was being lost from the burns.

Operation under continuous 'Pentothal' anæsthesia. All the second- and third-degree burns of face and ears, including the lips and the inside of the mouth, the second- and third-degree burns of both hands, with gloving of the hands, and the second-degree burns of both knees (patient was in shorts at the time of burning) were cleansed and dressed with sulphanilamide powder and soft-paraffin gauze, and the hands were immobilised in the position of function in plaster.

During anæsthesia vast quantities of mucus welled up into the trachea, and patient became very cyanotic despite the administration of oxygen. Pulmonary œdema was diagnosed on the additional evidence of widespread coarse crepitations in the chest. The administration of the anæsthetic agent was stopped, atropine gr. $^1/_{50}$ was given intravenously, and the trachea was sucked out under direct vision. During the latter procedure, burning of the larynx was observed by the anæsthetist.

As the effects of the pentothal wore off, the cough reflex returned, and further quantities of mucus came within the scope of the suction tube. At the same time double-strength plasma was substituted for normal plasma until 400 c.cm. had been administered. This was followed by a slow normal plasma drip. Twenty minutes later, on leaving the theatre, patient's colour was good, and moist sounds in the chest, previously abundant, were reduced to a remarkable degree.

There was no tendency for the pulmonary œdema to recur, and thirty hours later the patient was fit for evacuation to a base hospital.

In this case it was considered that the pulmonary œdema was the result of burns of the respiratory tract.

CASE 2.—A lance-corporal, on admission to an advanced surgical centre, was extremely ill owing to a sucking wound of the right midaxillary line caused by a machine gun bullet, and other injuries.

No details are available of the preoperative infusions administered, but the resuscitation was being carried out by an officer whose realisation of the dangers of transfusion in recent chest injuries was such that he had to be persuaded to give any infusions, and then gave them only very sparingly.

Operation under chloroform and ether followed by ether administered by the Oxford vaporiser (field surgical units did not carry gas-and-oxygen in those days). An obvious sucking hæmopneumothorax was present in the right midaxillary line. The abdomen showed no definite signs of penetration.

The chest wound was laid open and a fracture of the sixth rib found. The soft tissues were excised, and enough of the fractured rib was removed to permit inspection of the pleural cavity. A large hæmatoma of the lower lobe of the lung was seen, and there was no visible rent in the diaphragm. The wound was closed in layers. A perforating wound of the right elbow, related to the chest wound, shattering the lower end of the humerus and the elbow-joint, was excised and immobilised in a padded plaster. A perforating wound of the buttock required no operation. At the end of operation, hæmoptysis was observed.

After return to the ward, patient's condition was extremely grave, and oxygen was administered continuously. During the next three or four hours there was a gradual recovery, and consciousness was regained for a short period. About six hours after operation the patient gradually lost consciousness and appeared to be moribund, and large quantities of mucus welled up into the trachea. Widespread coarse crepitations were heard in the chest.

Treatment was instituted along the lines already described, double-strength plasma being used. The immediate response was dramatic, owing to clearing of the airway by suction followed by administration of oxygen, and over the next half-hour the moist sounds in the chest were observed to be diminishing. This "drying" effect continued, and the œdema did not tend to recur. Consciousness was regained half an hour after treatment was begun.

Five days later patient was fit for evacuation, there having been no further evidence of pulmonary œdema. Six weeks later it was learnt that the chest was considered as healed and only the orthopædic problem of the shattered elbow remained.

CASE 3.—An officer was injured by the explosion of a mine under the jeep in which he was riding. The force of the explosion was such that the jeep disintegrated and large parts of it (and of his fellow passenger) were never found.

On admission to an advanced surgical centre patient was cold, clammy, pulseless, unconscious, and appeared moribund, with a blood-pressure of 50/? The prognosis was hopeless.

The injuries were (1) bilateral blast injury of the lungs, diagnosed on the history, cyanosis, some respiratory embarrassment, and widespread coarse crepitations throughout both lungs; (2) a very large laceration of the sagittal line of the scalp without obvious fracture of the skull, which suggested that his head had met with sufficient violence to cause loss of consciousness; (3) lacerations over the left parietal and occipital regions of the scalp; (4) a traumatic amputation of the right forearm, with shattering of the elbow-joint and fracture of the lower end of the humerus on the same side, with great coincident muscle damage; (5) two penetrating wounds of the right shoulder region; (6) a simple fracture of the left medial malleolus, with much bruising and great displacement of the fragment; and (7) severe contusion of the right ankle.

The blast injuries of the lung were regarded as being of the greatest immediate seriousness. It was felt that there was almost no hope that the patient would become fit to stand operation. Blood-loss had obviously been severe, so blood-transfusion was started slowly because of the chest condition. After two pints of blood had been administered there was no evidence of any response. Pulmonary œdema then manifested itself, pink frothy sputum welling up from the trachea. The depth of unconsciousness was such that the cough reflex was absent.

Treatment was begun with atropine gr. $^{1}/_{50}$ intravenously, tracheal suction, and continuous oxygen. Coramine 5 c.cm. was given intravenously while the tracheal suction was being carried out, and a temporary but helpful return of the cough reflex was obtained. Triple-strength plasma 400 c.cm. was administered at a rate of 80 drops a minute.

In half an hour the colour had notably improved and the pulmonary œdema was disappearing. The cold clamminess of the body had been replaced by general warmth and superficial vasodilatation. The blood-pressure was rising steadily but slowly. Three hours after starting treatment for the pulmonary œdema the blood-pressure had reached 110/80, and the pulmonary œdema did not tend to recur. Semi-coma still persisted. It was now judged to be the suitable moment for operation (eight hours after admission and at least twelve hours after wounding).

Operation, under very light pentothal anæsthesia, consisted of rapid reamputation of the arm through the level of the fracture of the humerus, excision of all other wounds, and rapid one-layer closure of the scalp wound over sulphanilamide powder. The fractured ankle was manipulated and a padded plaster applied.

The condition of the patient did not deteriorate during the operation, but in the next two hours after operation the axillary temperature rose to nearly 105° F, beginning to fall thereafter on the application of cooling measures. This hyperpyrexia could have been the result of a reaction to the plasma or of some injury near the heat-regulating centre, and did not recur.

Ten months later patient was alive and well, having recovered from severe psychological disturbances which were present on his return to consciousness.

CASE 4.*—A sepoy, by the explosion of a shell very close to him, received multiple injuries, including a badly shattered right femur, with very gross and extensive muscle damage, necessitating high thigh amputation.

After operation the breathing became difficult, cyanosis appeared, and the semiconscious patient made poor attempts to cough up the large quantities of mucus in his bronchial tree. Coarse crepitations could be heard throughout the chest. Early pulmonary œdema was diagnosed, and treatment was begun with 400 c.cm. of triple-strength plasma, followed by 400 c.cm. of double-strength plasma. This produced a resolution of the pulmonary œdema, which did not tend to recur. However, patient gradually became more unconscious, despite the absence of external evidence of head injury, and died three days after being wounded.

As the patient was an Indian a necropsy was not done. The differential diagnosis lay between blast injury of the lung and brain, fat-embolism, and a combination of both. In any case naked-eye necropsy in the field would not have established a final diagnosis.

The important fact remains that the pulmonary œdema was controlled and death was due to the cerebral condition.

CASE 5.—A guardsman had been injured by a shell which landed so close to him that, when he came to, he found himself lying on the edge of the shell crater. His only external injury was a tangential laceration of the knee, just involving the joint without damaging the bone.

On admission his breathing was laboured, pulse-rate rapid, and he was slightly cyanosed. No mucus was welling up into his trachea, but high-pitched rhonchi were heard all over the lungs. He was a very much sicker man than his external injury warranted, and he was diagnosed as a case of early and perhaps slight blast injury of the lungs. Later he coughed up a little blood, which tended to substantiate the diagnosis.

He was given 400 c.cm. of triple-strength plasma at about 80 drops a minute. A severe rigor came on after about 200 c.cm. had been given. The rate of administration was diminished and morphine gr. $^{1}/_{4}$ administered, after which the rigor ceased.

Within an hour the cyanosis had disappeared, breathing had become easy, and the general condition had improved. No operation was performed beyond injection of the knee-joint with penicillin and applying suitable splintage. No further anxiety was caused by his chest condition.

This case is described because it is justifiable to suppose that concentrated plasma played a part in averting pulmonary œdema.

COMMENT

It appears clear that the initial improvement in the cases of pulmonary œdema described above can be attributed to the standard measures applied. The outstanding advantage which appears to result from the use of concentrated plasma is the tendency for progressive improvement and the remarkable absence of any tendency for the condition to recur. No case which is described above has required more than one clearing of the trachea by suction.

DANGERS OF CONCENTRATED PLASMA

Reactions of various degrees of intensity may arise, but these do not differ from the reactions which may arise when normal plasma is used to replace plasma loss. Excluding those cases in which bad plasma is used mistakenly, reactions only appear to be really dangerous when a serious hyperpyrexia develops. By careful observation this may be anticipated and the infusion stopped. If, on the other hand, it appears that death is a certainty from the pulmonary œdema unless administration of the plasma is continued, a fresh amount of plasma may be prepared and given through a fresh giving set, and the pyrexia controlled by the usual cooling measures.

In cases where the pulmonary œdema is caused by overtransfusion, an adequate venesection is a necessary preliminary to the use of the concentrated plasma, or the condition will be aggravated. I have seen such a case treated mistakenly with triple-strength plasma without venesection, with aggravation of the condition. This case subsequently responded to venesection when the error was pointed out. I have used it in such a condition, after ordering a preliminary venesection, and been well pleased with the rate of return to normal of the lungs.

---

* This patient and case 5 were treated with concentrated plasma, at my suggestion, by Major D. E. Stephens, S.A.M.C., to whom I am indebted for the case-records.

SUMMARY

Intravenous concentrated plasma has seemed to be a valuable addition to recognised methods in the treatment of pulmonary œdema due to trauma.

Illustrative cases are described.

There has been no tendency for the pulmonary œdema to recur, in the types of cases described, after this treatment.

Apart from the risk of reactions to the plasma, the method is dangerous only if applied, without preliminary venesection, in cases of pulmonary œdema due to overtransfusion.

ACUTE PHOSGENE POISONING

EFFECTS OF PLASMA REPLACEMENT

EXPERIMENTS WITH DOGS AND GOATS

COLSTON RESEARCH FELLOW 1935–37

From the Experimental Station, Porton, Wilts

DURING the war 1914–18 two types of clinical cases were observed in men exposed to lung-irritant gases: the "blue" case and the "grey" case.[1] The "blue" case showed congested veins and was benefited by venesection. In the "grey" case severe circulatory collapse and leaden cyanosis, with rapid thready pulse, were evident.

In the experiments described by Cameron and Courtice[2] and in other experiments where dogs and goats have been exposed to pure phosgene, signs resembling those of the "blue" case in man have not been seen. As œdema develops, the plasma volume falls, the blood concentrates, the peripheral veins collapse, and the blood-pressure is maintained at first but fails later. Acute phosgene poisoning in these animals thus resembles the "grey" case seen in man.

The logical treatment of such cases of phosgene poisoning would be transfusions of plasma or serum, to maintain the falling plasma volume and so improve the general circulation. The picture is complicated, however, by the fact that the animal is at the same time suffering from anoxæmia due to insufficient oxygenation of the blood in the lungs. The experiments of Cameron and Courtice suggest that, as the lung capillaries appear to be completely permeable to the plasma proteins, any transfusion of a protein solution to improve the general circulation would at the same time increase the pulmonary œdema and so decrease the degree of oxygenation of the blood in the lungs. It was hoped, however, that, by improving the peripheral circulation, the increased blood-flow to the tissues would counteract any decreased oxygenation of the blood in the lungs. The effects of plasma, serum, and concentrated serum were therefore investigated in dogs and goats after exposure to phosgene.

METHODS

Unanæsthetised dogs and goats were exposed to phosgene (440 mg. per cubic metre for various times) in a static chamber and were transfused about sixteen hours after exposure when hæmoconcentration was well marked.

The plasma or serum was given by drip transfusion into a vein in the foreleg. The animal remained quietly on a table during the course of the transfusion, which usually took 30 min. The drip apparatus used for human transfusions in the Army was used. The amount of fluid given was calculated from the rise in Hb % caused by the phosgene before the transfusion began. When four-times-concentrated serum was given, the amount was only a quarter of the calculated plasma loss.

Blood samples were taken from the jugular vein before exposure to phosgene, sixteen hours after exposure, and immediately after, and two, six, twenty-four, and forty-eight hours after transfusion if the animal survived. The Hb % and plasma-protein concentration of the blood samples were estimated, the former by the Haldane hæmoglobinometer, and the latter by microkjeldahl digestion and nesslerisation. The serum or plasma given *did not cause agglutination* of the recipient's cells in any case.

Dog serum and plasma were used in these experiments with dogs, and goat serum and plasma with goats. To obtain the plasma and serum, normal dogs and goats were bled about 20% of their blood-volume by venepuncture of the jugular vein and suction. Strict aseptic precautions were taken. The dog serum was dried by the Army Transfusion Unit and was reconstituted when required as normal or four-times-concentrated serum. The dog plasma and the goat serum and plasma were all used fresh.

RESULTS IN DOGS

In these experiments 13 dogs have been transfused: 5 with four-times-concentrated serum, 4 with normal serum, and 4 with normal plasma. The results of all experiments have been similar.

Four-times-concentrated Serum.—Two dogs were exposed to the phosgene concentration for 10 min. Both were very ill sixteen hours later, with laboured respiration, cyanosis, and collapsed peripheral veins, the Hb of one having risen from 81% to 114%, and the other from 80% to 108%. After transfusion the symptoms became much worse, one dog dying two hours after, and the other seven hours after, transfusion.

Six other dogs were exposed for a shorter time, 6 min., to the same concentration of phosgene. The general symptoms of these dogs sixteen hours later were not so severe as those of the first 2 dogs. Three were transfused with four-times-concentrated serum, and 3 were left as controls. Fig. 1*b* shows the mean results of the two groups. The degree of hæmoconcentration was much the same in both groups sixteen hours after exposure to phosgene. Immediately after transfusion, in the treated group, the Hb % fell slightly, but two hours later it had risen again to a level above that before treatment. Thereafter the level of hæmoconcentration ran parallel with that in the control group. The plasma-protein concentration in the treated group was maintained by the proteins transfused; but, even so, much of the protein injected must have left the circulation. The treated animals were clinically worse after the treatment; but, as the pulmonary œdema was not too severe at the beginning, they all survived in spite of the transfusion. It was felt that, if a second transfusion had been given to try to dilute the blood, death would have resulted.

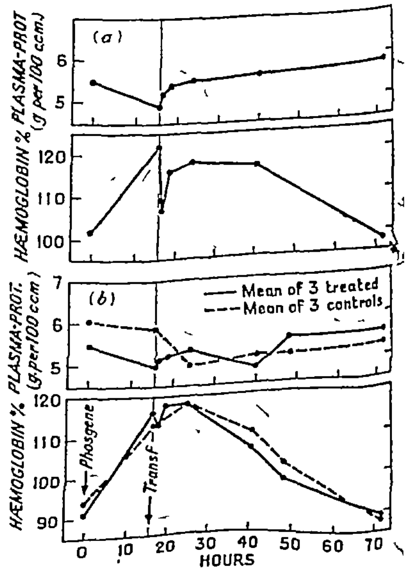

Fig. 1—Effects of transfusion after exposure to phosgene in dogs: (*a*) transfusion with normal serum; (*b*) transfusion with four-times-concentrated serum.

[2] Cameron, G. R., Courtice, F. C. *J. Physiol.* 1946, 105, 175.

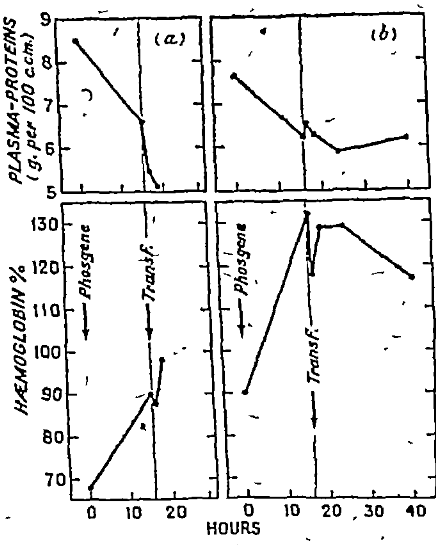

Fig. 2—Effects of transfusion after exposure to phosgene in goats: (a) transfusion with normal plasma; (b) transfusion with normal serum.

Concentrated serum, which contained 22–24% of protein by analysis, therefore had no lasting osmotic effect in withdrawing fluid back into the circulation from the lungs. On the contrary, the fluid, together with the protein it contained, rapidly passed out of the circulation, and presumably some of it passed into the lungs, thereby increasing the degree of anoxæmia.

Normal Reconstituted Serum.—Of the 4 phosgenised dogs transfused with normal serum, 1 died two hours after, and 1 six hours after, transfusion, and 2 survived. In 1 case there was no hæmodilution, and in the other 3 dilution was transient. The general condition of the dogs, as determined by rate and type of respiration, cyanosis of tongue and gums, and sounds in the chest on stethoscopic examination, was worse in all cases after the transfusion. Fig. 1*a* shows the effects in one of the dogs that survived. The plasma-protein level was raised, but the hæmodilution which took place immediately after the transfusion was not maintained.

Fresh Normal Plasma.—Of the 4 phosgenised dogs transfused with plasma, 1 died two hours after the transfusion and 3 survived. Hæmodilution in all cases was transient; and since the condition of the dogs was worsened by the transfusion, it was thought that a further transfusion would have led to death. The plasma-protein level fell even more in all cases after transfusion.

RESULTS IN GOATS

Three goats were transfused with normal plasma and 2 with normal serum. The results of all experiments were similar. Two typical experiments are depicted in fig. 2. The general behaviour of goats closely resembled that of dogs. The transfused fluid had either a temporary effect or none at all in diluting the blood, and the general condition of the animal was always very much worse after transfusion.

DISCUSSION

From all these experiments the following conclusions may be drawn:

(1) The fluid transfused, whether concentrated serum, normal serum, or normal plasma, passed out of the circulation very quickly, depending, on the whole, on the severity of the symptoms before transfusion.

(2) The proteins of the transfused fluids also left the circulation, but serum had a better effect than plasma in maintaining or slightly raising the plasma-protein concentration.

(3) The general condition of the animal was invariably much worse as a result of the transfusion.

(4) It was impossible in very severe cases of phosgene poisoning ever to give enough fluid by drip transfusion to dilute the blood, so rapidly did it pass into the lungs. In less severe cases the dilution of the blood was only temporary after a single transfusion, but the clinical condition of the animal was made much worse; hence a second transfusion would almost certainly have led to death.

This question of transfusion in cases of hæmoconcentration and peripheral circulatory collapse in the presence of pulmonary œdema has arisen in conditions other than phosgene poisoning—e.g., after inhalation of nitrous fumes and other irritant gases. Presumably in all such cases of pulmonary œdema the capillaries of the lungs are affected. The experiments described show that these capillaries allow the passage of the normal plasma of the animal in the first instance, and likewise of the transfused plasma or serum. It was hoped that concentrated serum would, temporarily at least, withdraw some of the œdema fluid by osmotic action, as the transfused serum passes through the pulmonary circulation before the general systemic capillary bed. This hope was not justified by the experiments with dogs. Transfusions in the presence of gross pulmonary œdema are therefore definitely detrimental.

It is possible to have cases of shock due to thermal burns accompanied by only a slight degree of pulmonary œdema due to the inhalation of irritant gases such as nitrous fumes. In such cases great care should be taken if transfusions are given, as it is probable that a non-lethal exposure to a lung-irritant gas can easily be made lethal by repeated transfusions of plasma or serum.

SUMMARY

The effects of transfusions of four-times-concentrated serum and of normal plasma and serum have been investigated in dogs and goats with phosgene poisoning.

The transfusions have no lasting effect in relieving the hæmoconcentration and have a definite detrimental effect by increasing the pulmonary œdema. Transfusions are therefore contra-indicated in the presence of gross pulmonary œdema.

We are indebted to Brigadier Sir Lionel Whitby, of the Army Transfusion Service, for drying the dog serum used in these experiments. Our acknowledgments are also due to the Director-General, Scientific Research and Development, Ministry of Supply, for permission to publish this investigation.

SALT DEFICIENCY IN SPRUE

D. A. K. BLACK
M.D. St. And., M.R.C.P.
MAJOR R.A.M.C.; MEMBER OF G.H.Q. (1) SPRUE INVESTIGATION TEAM AND CENTRAL MILITARY PATHOLOGICAL LABORATORY

It is well recognised that in both tropical and non-tropical sprue the blood-pressure is lower than normal in some patients. Thaysen (1932) found a systolic blood-pressure of less than 100 mm. Hg in 7 of 13 patients with non-tropical sprue. Though a fall in blood-pressure is more common in long-standing cases of sprue, it is also found in some soldiers who contract the disease on war-time overseas service; of 41 soldiers with sprue who had been in India for four years or less, 4 had a systolic blood-pressure of less than 100 mm. Hg and a diastolic of less than 65 mm. Hg. Some such patients show not only hypotension but also signs of peripheral circulatory failure; these form an important group, in spite of their small numbers, for the occasional fatal case of early sprue is drawn from their ranks. The cause of the hypotension presents something of a problem, for in these early cases anæmia has not become gross. Moreover protracted malnutrition cannot be accepted as the sole cause of the hypotension, which may be observed in patients who are not conspicuously wasted in comparison with others who have had the disease for longer periods but whose blood-pressure has remained normal. The present series of observations was directed towards finding some more adequate explanation of the low blood-pressure in this group of patients.

Methods.—The following analytical methods were used:

Serum-sodium: uranyl zinc acetate precipitation.
Serum-potassium: cobalti-nitrite precipitation.
Serum-chloride: Volhard-Harvey titration.
Blood-urea: urease-Nesslerisation.
Plasma volume: vital-red method.

Chloride was determined in urine and stools by the open Carius method; sodium and potassium were determined on ash extracts of stools and urine.

GENERAL CLINICAL FEATURES

The ten patients investigated all had tropical sprue, contracted during their period of service in the India-Burma theatre of war. All of them had steatorrhœa, fat accounting for more than 30% of the dry stool weight. All had lost 10 kg. or more of body-weight. Glossitis was common but not constant. The duration of symptoms was less than a year, and none of the cases showed the severe degree of anæmia which is common in sprue patients coming under observation at a later stage of the disease. The appetite was capricious, and in several cases reluctance to take adequate amounts of food and fluid interfered with therapy; thirst was not complained of. Abdominal distension was general. Two of the patients had profuse watery diarrhœa at the time of investigation, and several others gave a history of diarrhœic episodes, separated by longer periods in which the stools were pale and bulky but well formed. A few of the patients, but not all, had had cramps.

These ten patients were selected from several hundred cases of sprue which passed through the same hospital in 15 months. The basis of selection was low blood-pressure with asthenia. All the patients in the series had a diastolic blood-pressure of 70 mm. Hg or less; the lowest blood-pressure recorded was 74/45 mm. Hg. Though "asthenia" cannot be reduced to quantitative terms, these patients formed in this respect a sharply differentiated group. The great majority of patients with steatorrhœa of a few months' duration are surprisingly well, even though they may have lost much weight; but the patients in our series were listless, lay flat in bed, and were incapable of exertion. The superficial veins were collapsed, and the pulse was thin and rapid. The muscles and subcutaneous tissues were flaccid, and the skin wrinkled, more so than in other patients who had lost a comparable amount of weight. The skin was pale, though they were not anæmic.

The following case-record may be taken as representative of the more severely ill patients in the series.

ILLUSTRATIVE CASE-RECORD

A man (case 10), aged 22 years, with a year's tropical service, had had, since 1939, epigastric pain, heartburn, and occasional vomiting after fatty meals. A barium meal had not disclosed any abnormality. No previous diarrhœa, dysentery, or malaria.

The serum-potassium on Sept. 23 was 20·2 mg/100 ml. The alkal reserve on Sept. 29 was 47·3 vol/100 ml.

Present illness began in May, 1945, when he was in Eastern Bengal. The onset was sudden, with the passage of copious frothy watery stools. Loss of appetite and abdominal distension were present from the beginning, and he became very weak. Flatulence and abdominal discomfort were prominent symptoms from the onset, whereas tongue signs did not appear until 3 months after the diarrhœa began. He was evacuated to base, and admitted to this hospital on Sept. 20, 1945.

On admission he was severely ill and showed clinical sign of dehydration: dry wrinkled skin, coated tongue, an diminished intraocular tension. Pulse weak and dicrot superficial veins noticeably collapsed. Blood-pressure 100/ fell to 90/65 when the man sat up; pulse-rate 90, rising to 96 on sitting. Appetite poor, but he took fluids well. Tongue painful and reddened at the tip and sides, depapillated, but not fissured. Abdominal distension present, with flatulence Patient passing ten pale fluid copious stools daily.

The patient's weight was 87 lb., his normal weight bei 154 lb. A blood-count showed Hb 12 g./100 ml., red c 3,000,000 per c.mm. A 3-day specimen of fæces weigh 3·5 kg., the dry weight being 239 g. This contained 36% fat, the total output of fat in 3 days being 87 g., of whi 82 g. were split. No mucus or inflammatory exudate w found in the stools.

Progress.—Patient was put on a sprue diet containi 118 g. of protein, 45 g. of fat, and 159 g. of carbohydrate day, the total calorie intake being 1513 a day. This d contains less than 5 g. of salt a day, and it was supplement during the first three days of observation by 5 g. of salt bring the salt content nearer a normal level. Even on t diet, comparatively restricted in salt, the serum-sodium le rose, and concurrently the patient's circulatory state improv so that by Sept. 24, four days after admission, his pulse-r had fallen to 72 per min., and his blood-pressure was 104/ mm. Hg lying, but rose to 110/75 mm. Hg on sitting up.

After three days on a "normal salt" diet the patient w put on a "high salt" diet, with 25 g. of added salt a da this had to be reduced after three days to 15 g., for t patient's appetite became capricious, and he passed increas amounts of watery stools.

Specific sprue therapy with parenteral liver extract w begun, and sulphaguanidine was given in a total dosage 70 g. in four days; the stools became formed within thr days, the wet weight being 300 g. a day.

The general condition improved rapidly, and a month aft the start of treatment the patient's weight had risen fro 87 to 128 lb. His blood-pressure was normal, tongue sig had disappeared, and he felt well, though his stools remain bulky and he was passing 96 g. of fat in three days.

LABORATORY FINDINGS

In table I are given the results of the estimation plasma volume and hæmatocrit, and of serum-sodiu serum-chloride, and serum-potassium in ten patient In the calculation of the plasma volume per kg. t patient's actual weight at the time of estimation has bee used; had the normal body-weight been used, the valu would have been lower by 10% or more.

Seven of the patients had a *plasma volume* of less tha 2·5 litres, and two of them less than 2·0 litres. Five of t patients had a plasma volume of less than 45 ml

The hæmatocrit readings lay mostly between 40% and 6%; but one high value of 50% and two low values of 36% and 37% were observed. Later estimations of the hæmatocrit percentage showed that these normal values did in fact represent a moderate hæmoconcentration: for, when the plasma volume rose with therapy, the hæmatocrit percentage fell to values just below the usual normal limits. The *serum-sodium* values were uniformly low, ranging from 288 to 320 mg./100 ml. (112 to 139 mEq./litre). A control series of five sprue patients with gross steatorrhœa, but with a normal blood-pressure, gave values for the serum-sodium ranging from 318 to 354 mg./100 ml. Moreover, normal values were found for the serum-sodium in four of the patients reported in table I, on whom it was possible to obtain a blood sample after recovery. The *serum-chlorides* were also low, but less markedly so than the serum-sodiums (range 515–608 mg./100 ml., 88–104 mEq./litre). The *serum-potassium* was done in seven patients, and in none of them did it exceed the upper limit of normal. The highest *blood-urea* was 60 mg./100 ml., and in five other patients the blood-urea was over 40 mg./100 ml.

This group of observations indicated that in these patients hypotension and circulatory failure were associated with low serum-sodium and serum-chloride levels, and less constantly with a low plasma volume. They gave no evidence whether the observed sodium deficiency was caused by inadequate intake or by excessive loss of electrolytes, or whether diminished activity of the suprarenal gland might be responsible for the hypotension, as suggested by Thaysen (1932). In the later patients of the series, treatment with salt, either by mouth or intravenously, was followed by the disappearance of the circulatory collapse, and the serum-sodium rather slowly returned to normal levels. The excretion of chloride in the urine was low, of the order of 3–5 g. a day, but chlorides were never absent from the urine The urine and fæces of case 10 were collected over a 15-day period after his admission, and again for a 3-day period after he had completely recovered from dehydration, but while he was still passing large amounts of fat in the fæces. Tables II–V give the results of blood, urine, and stool analysis, and the mineral intake and output for corresponding periods.

TABLE III—URINE ANALYSES IN CASE 10

Period	Vol. ml	Sp gr	Sodium		Chloride		Potassium		Urea g	Urea clearance: % of average normal
			g	mEq	g	mEq	g	mEq		
1	3135	1·012	0·14	6·1	4·7	132	0·12	3·1	57	80
2	4415	1·012	0·31	13·5	14·6	412	1·06	27·2	59	63
3	3000	1·010	0·21	9·1	10·2	288	0·68	17·4	40	46
4	4830	1·006	1·03	44·8	8·6	242	0·65	16·7	44	50
5	3640	1·007	1·08	47·0	9·2	259	0·75	19·2	97	85
After	7570	1·031	17·5	762·0	30·5	860	3·0	77·0	53	86

All periods are of three days, and the figures for sodium, chloride, potassium, and urea represent the total excretions in each period. Periods 1–5 are consecutive, starting from Sept. 22; the "after" period was the three days Nov. 12–14, at which time the patient had a normal blood-pressure but was still passing fatty stools.

The blood estimations (table II) showed a low serum-sodium level which rose rapidly when salt was added to the diet. The serum-chloride level was not so low as the serum-sodium initially, and it rose to within normal limits more rapidly. The initial plasma volume was lower than the value obtained after recovery, but the difference was not striking. The hæmatocrit percentage fell when dehydration was corrected, and later rose again to a normal value as the patient's general state improved. The blood-urea level during the dehydration period lay within the normal range but was higher than after recovery; Kirsner et al. (1943) comment on the fact that blood-urea may show little increase in moderate degrees of salt deficiency. However, the urea clearance (table III) was depressed at the time when the blood-urea level was highest, and the 3-day output of urea also fell. Comparison of the results in table II with the clinical data in the appended case-record on patient 10 shows that correction of the anomalous blood findings was attended by only partial clinical improvement. The pulse-rate fell, the blood-pressure rose, and the peripheral circulation improved. There was some gain in weight, but the patient continued to pass very large fluid stools, his appetite was poor, and he felt no better. It was obvious that salt deficiency had been responsible for only a part of the complex clinical picture, and rapid improvement in his general condition took place only after he was treated with sulphaguanidine and parenteral liver.

TABLE IV—FÆCAL ANALYSIS IN CASE 10

Period	Wet weight g	Dry weight g	Total fat g	Sodium		Chloride		Potassium	
				g	mEq	g	mEq	g	mEq

MINERAL BALANCE AND EXCRETION

There was retention of sodium, chloride, and potassium throughout the first observation period of 15 days. In the case of sodium and chloride, this took place on dietary intakes varying from less than 10 g. to more than 20 g. of sodium-chloride a day, even though abnormal amounts of sodium and chloride were being lost in the stools. The retention of sodium and chloride was accompanied by a rise in their serum concentrations. In the after-period of three days the patient was in sodium balance and was excreting rather more chloride than he took in; there was still a retention of potassium, which may have been related to the fact that he was still putting on weight rapidly. Though the dietary intake of sodium and chloride, when expressed in milli-equivalents, was approximately equal, more sodium than chloride was retained, except during period 1, when the patient was on a diet containing less than 10 g. of salt a day. This suggests that in the period before our observations,

TABLE V—INTAKE AND OUTPUT OF ELECTROLYTES IN CASE 10

Period	Intake						Output					
	Sodium		Chloride		Potassium		Sodium		Chloride		Potassium	
	g	mEq	g	mEq	g	mEq	g	mEq	g	mEq	g	mEq
1	10·1	440	16·7	470	10·3	264	4·6	206	5·9	166	1·1	29
2	27·8	1210	43·0	1210	9·9	254	9·2	401	22·7	640	2·9	73
3	20·0	870	31·2	852	7·9	206	9·2	401	14·2	401	5·6	143
4	12·8	557	20·0	563	4·2	108	4·4	193	10·7	301	2·7	68
5	10·9	474	17·9	504	8·8	226	1·9	82	9·6	270	3·6	91
After	18·2	792	28·4	800	11·0	282	18·0	791	30·5	861	7·1	182

The potassium intake was derived entirely from the food, and its variability was due to the patient's having been unable to take different items of the measured diet at different times. The sodium and chloride were derived partly from the diet, and partly from supplementary sodium chloride, to the amount of 5 g/day in period 1, 25 g/day in period 2, 15 g/day in period 3, and 10 g/day in periods 4 and 5 and the "after" period.

when salt deficiency was actually developing, loss of sodium had exceeded loss of chloride. Even in the observation period loss of sodium in the stools was much greater than loss of chloride; and normal intestinal secretion is known to contain more sodium than chloride (Gamble et al. 1945). The total loss of sodium and chloride in the stools was greatly in excess of the negligible amounts found in normal stools. Even in the after-period, though chloride was practically absent from the stools, they still contained 0·5 g. of sodium in three days; at this stage the stool was still bulky and contained much fat, but the ratio of dry to wet weight was within normal limits. The greater loss of sodium than of chloride in the stools was clearly reflected in the urinary excretion of these ions. In the first observation period the urine contained only 6·1 mEq. of sodium in 3 days, whereas in the same time 132 mEq. of chloride was excreted. After some days on diet with added salt, the chloride output in the urine was still more than five times as great as the sodium output. Only in the after-period were sodium and chloride excreted in equivalent amounts. These findings indicate that salt deficiency in this patient was complicated by acidosis; the kidneys conserved base rigidly but continued to excrete chloride in significant amounts. Further evidence of acidosis may be found in the alkali reserve of 47·3 vol./100 ml. and in the finding of 113 mEq. of ammonia plus titratable acidity in one 24-hour specimen of urine.

DISCUSSION

The clinical and laboratory findings in these patients are those of dehydration due to salt deficiency. Similar episodes of dehydration are not uncommon in cœliac disease, and Prunty and Macoun (1943) describe a case of non-tropical steatorrhœa with hypotension and low serum-sodium and serum-chloride levels. The comparative frequency of salt deficiency as a complication of tropical sprue does not seem to have been appreciated, for electrolyte studies in this disease have been almost confined to calcium and phosphorus metabolism.

The chief cause of salt deficiency in these patients is almost certainly the loss of sodium and chloride in the bulky, often fluid, stools. It may be left an open question whether the sodium and chloride in the stools represent unabsorbed dietary salt, or intestinal secretion which has not been reabsorbed in the usual way. The greater loss of sodium than of chloride suggests that intestinal secretions form a large part of the fluid stool. On the other hand, increasing the intake of saline fluid in case 10 was followed by a threefold increase in the bulk of the stool, which decreased again when the saline intake was reduced. Visscher et al. (1944) have shown that absorption of sodium, chloride, and even water is not a simple process of diffusion, but may differ by 200-fold from rates calculated from concentrations of these substances; and it is not impossible that an active process of this kind should be impaired in severe sprue, or even in chronic starvation. Although diarrhœa is the main cause of salt deficiency in these patients, the salt intake is also concerned; anorexia interferes with the intake of salt and salt-containing foods, and thirst is relieved by fluids which contain little or no salt. Our observations suggest that adrenal insufficiency, suggested by Thaysen (1932) as a cause of hypotension in steatorrhœa, was not an important factor in our patients. No increase in the serum-potassium was observed; and in case 10 sodium was adequately retained by the kidneys. Moreover, Prunty and Macoun (1943), in their case of salt deficiency in idiopathic steatorrhœa, found no biochemical evidence of adrenocortical deficiency. Sprue patients with hypotension do not respond clinically to therapy with desoxycorticosterone acetate (Leishman 1945).

Therapeutic Implications.—When the likelihood of salt deficiency in cases of sprue with profuse diarrhœa is appreciated, much can be done in the way of prophylaxis. The diets normally used in the treatment of sprue are of no more than average salt content, and they require to be supplemented by the liberal addition of salt in cooking and seasoning, in any patient who develops diarrhœa. When anorexia interferes with the intake of food, it becomes even more important to give salt besides fluid. Skimmed milk, which forms a high proportion of the early sprue diet, contains less than 0·2 g. of salt per 100 ml.; the addition of 0·3 g./100 ml. (1·5 g. per pint) is well tolerated. Orange-juice and lemon-juice, fortified by 0·45 g. of salt per 100 ml., are suitable as drinks, and we have found that sprue patients take them well. A daily intake of 15 g. of salt should be aimed at in the sprue patient with diarrhœa in the tropics; the actual food in a sprue diet supplies only 5 g. of this, and the remaining 10 g. has to be added in seasoning and in weak saline drinks.

In established salt deficiency more intensive salt therapy by mouth has to be given. Though these patients do not usually complain of thirst they take saline fluids well. The limit to the amount of saline fluid which can be given by mouth is set by increase of diarrhœa, and improvement on oral therapy may take some days. In only one patient of this series was it necessary to give saline by vein. Even more important than replacement therapy is the necessity of cutting short the watery diarrhœa which is present in nearly all these patients. Though the stools have not shown the exudate of bacillary dysentery, sulphaguanidine has been found effective in four patients of this series whose diarrhœa did not respond to diet and rest in bed. Parenteral liver should also be given as part of the general treatment.

With treatment on the lines suggested, all the patients in this series made a good recovery from their acute state of circulatory insufficiency. The stool fats, as might be expected, were not restored to normal, though they became less when diarrhœa was arrested. The patients were, however, brought from a state in which they seemed likely to succumb to one in which routine therapy for sprue could be applied and take effect.

SUMMARY

Between 5% and 10% of patients with sprue acquired on military service have had a low blood-pressure, asthenia, and signs of peripheral circulatory failure.

Ten such patients had low serum-sodium and serum-chloride levels, and in some cases a plasma volume which was low in relation to body-weight. Of these abnormalities the low serum-sodium level was the most pronounced.

A balance experiment on a typical patient showed abnormal loss of sodium, and to a less extent of chloride, in the fæces; in the urine, sodium was rigidly conserved, while chloride was excreted, though in amounts less than normal.

When the patient was put on a high intake of salt, sodium and chloride were both retained, and the serum-sodium and serum-chloride rose to normal levels; the blood-pressure rose, and clinical signs of dehydration disappeared, though the abnormal loss of fat in the stools was not affected.

It is considered that such patients show the clinical and biochemical pattern of salt deficiency, modified by some degree of acidosis, owing to the preponderant loss of sodium over chloride in the stools.

Loss of electrolyte in copious watery stools is thought to be the main cause of the salt deficiency, but diminished intake of salt in anorexic patients is also a factor.

The results reported do not suggest adrenal insufficiency, for the serum-potassium was not increased, and conservation of base by the kidneys was adequate.

Treatment by increasing the salt intake to 15 g. a day corrects the dehydration in a few days, and intravenous saline had to be given in one patient only.

If watery diarrhœa does not respond to diet and rest in bed, replacement salt therapy should be supplemented by sulphaguanidine, which has been found to check this type of diarrhœa.

I am indebted to the Director of Medical Services in India for permission to publish this paper, and to Colonel R. N. Phease, Officer Commanding Central Military Pathological Laboratory. The patients described were under the care of Lieut.-Colonels W. C. Smallwood and K. D. Keele, R.A.M.C., whose coöperation and interest in the work are much appreciated. I am grateful to Prof. R. A. McCance for many valuable suggestions both in planning and interpretation.

MYOCARDIAL FIBROSIS FOLLOWING ARSENICAL THERAPY

REPORT OF A CASE

J. R. EDGE
M.D. Leeds
FORMERLY RESIDENT MEDICAL OFFICER, PINDER FIELDS EMERGENCY HOSPITAL, WAKEFIELD

This case is reported in view of the rarity of focal myocarditis following arsenical treatment. I have not been able to discover any report of a case in which a patient recovered from arsenical coma and later died of chronic congestive heart-failure, apparently also due to arsenicals.

A man, aged 41, stationed in West Africa, noted a penile sore on Oct. 25, 1944. On Nov. 25 the sore was still present. Kahn reaction + + +. He started a course of weekly injections of neoarsphenamine; the sixth and last injection of the series was given on Dec. 28, 1944, and the sore healed.

On Jan. 26, 1945, a further injection of neoarsphenamine was given, and on the 29th he reported sick with malaise, headache, and weakness in both hands. On the 30th he became restless and irritable and rapidly lapsed into coma, responding only to painful stimuli. Temperature 102° F, very restless, tongue dry. No neck-rigidity. Fundi: veins congested, otherwise no abnormality. Cranial nerves normal. Apparent weakness of left arm and leg. Tendon jerks present and equal. Plantar responses flexor. An attempt at lumbar puncture failed. Given quinine gr. 10 t.i.d. (no record of blood films available).

On Feb. 2 his general condition had improved, but he was still unable to answer questions. Left arm and leg spastic, abdominal reflexes absent, both plantar responses extensor. By the 19th he could coöperate normally, but had no memory of events for the previous three weeks. The left arm was spastic, with greatly increased tendon jerks; coördination impaired in both arms. Abdominal jerks absent. Leg jerks equal; power and coördination normal; plantar responses flexor. He was slightly breathless at rest in bed, with œdema of the legs and sacral cushion. Heart not enlarged clinically; sounds faint; pulse of poor volume; blood-pressure 105/80 mm. Hg.

On May 19 orthopnœa increased, jugular veins overfilled and pulsating, œdema still present, liver enlarged, crepitations at both lung bases.

On June 16 he was admitted to Pinder Fields Hospital. He had no previous history of rheumatism; in spite of twelve attacks of malaria in two years, he said that he was in robust health until just after the injection of neoarsphenamine on Jan. 26, 1945. He had been a heavy beer drinker. His relations had noted no change in personality.

On examination: a coöperative patient, with moderate cyanosis of nose, ears, hands, and feet; breathing slightly laboured at rest in bed; veins of neck full to angles of mandible; pitting œdema of ankles and over sacrum; liver enlarged to percussion; spleen not palpable. Pulse-rate 110 per min., pulse regular but of poor volume; arteries not palpable; blood-pressure 115/90. Apex-beat diffuse; cardiac dullness extended 5½ in. to left of midline. Sounds faint; third heart sound present at apex; pulmonary second sound slightly increased; constant soft apical systolic bruit. Moist crepitations at bases of both lungs.

Central nervous system: residual spastic paresis of both arms, greater on the left, with grossly exaggerated tendon jerks and severe incoördination. Abdominal jerks absent: leg jerks present and equal; plantar responses flexor. No evidence of peripheral neuritis. Fundi: veins congested, otherwise no abnormality.

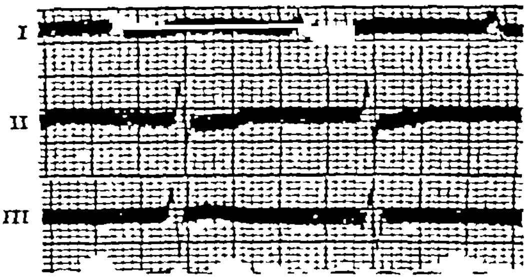

Fig. 1—Electrocardiogram: limb leads, showing small voltage, and diphasic flat T wave in leads I and II.

Radiography of chest (July 4) showed gross general cardiac enlargement: aortic arch normal; severe hilar and pulmonary congestion, especially at base of right lung. No evidence of tuberculosis.

Blood-count (July 4): Hb 86%, red cells 5,300,000, white cells 16,000 per c.mm. (polymorphs 41%, lymphocytes 18%, monocytes 4%, eosinophils 37%). Subsequent counts showed that the eosinophilia was maintained. Films persistently negative for malarial parasites.

Other investigations: test-meal showed acid secretion slightly below normal; stools repeatedly negative for parasites; no abnormalities in urine. Electrocardiogram showed a very small voltage in all limb leads, with a diphasic flat T wave in leads I and II (fig. 1). In the chest leads (fig. 2) the main deflection was downwards, and C.F.5 showed notching of the ventricular complex. Blood Wassermann and Kahn reactions on July 4 and August 1 were negative.

Diagnosis.—He presented the picture of chronic myocardial impairment without hypertension or evidence of rheumatic disease. Electrocardiography showed no evidence of bundle branch block or posterior wall infarction. Beriberi heart was a possibility. It seemed difficult to associate the condition with syphilis.

Treatment and Progress.—The congestion was slightly improved after treatment with mercurial diuretics; the pulse-rate dropped to 90 per min. Full doses of digitalis and intramuscular injections of 'Benerva' 50 mg. daily for fourteen days had no effect. His condition did not alter until early in August, when he developed a low-grade bronchopneumonia; the œdema then increased, and he became progressively drowsier and died on August 18. The pulse remained regular throughout.

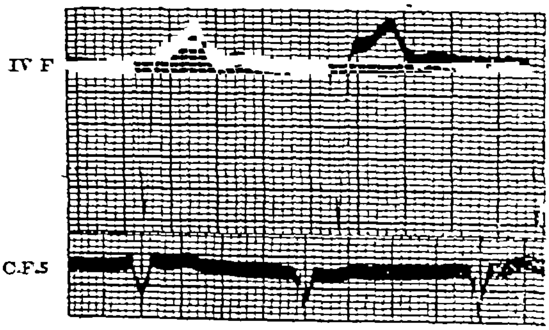

Fig. 2—Electrocardiogram: chest leads, showing main deflection downwards. C.F.5 shows notching of the ventricular complex.

NECROPSY

There was gross œdema of the legs, genitalia, and sacral cushion; no skin petechiæ. The peritoneum contained abundant clear fluid, and there was a large clear pleural effusion on the left side.

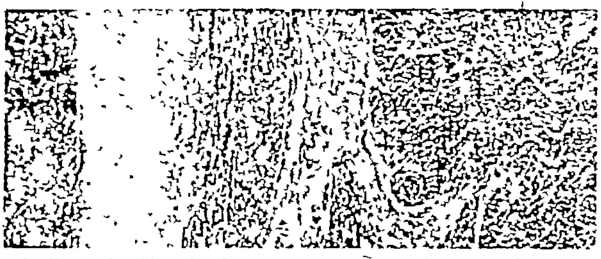

Fig. 3—Extensive fibrosis of myocardium, dense subendocardial fibrosis, and adherent mural thrombus. (H. and E. × 14.)

Heart weighed 520 g. Pericardium normal. Generalised dilatation of both ventricles; walls not thickened. Heart muscle pink and flabby; two minute fibrous scars in wall of left ventricle. Endocardium lining both ventricles greatly thickened, apical third of left ventricle being completely filled with greenish-red adherent thrombus; no thrombus found in any other chamber. Valves healthy; coronary arteries normal except for a small patch of atheroma $^1/_2$ in. from beginning of left coronary; aorta likewise healthy except for two small patches of atheroma in ascending part.

Lungs: left lower lobe collapsed; much congestion with terminal bronchopneumonia. No infarcts seen; no evidence of tubercle other than a thick adhesion at right apex.

Liver weighed 1950 g., with characteristic nutmeg changes. Spleen weighed 420 g.; capsule tense; pulp very firm, fibrous, and intensely congested. *Kidneys* congested; no infarcts. *Brain* œdematous; cut surface exuded free fluid; no other abnormality; no evidence of old thrombosis. *Intestines:* no parasites found.

Microscopical Examination.—Heart showed extensive focal myocardial fibrosis, evidently the result of complete healing of an antecedent necrotic process. The scars were very telangiectatic, and there was much hæmatogenous pigment in phagocytes. There was very dense subendocardial fibrosis, with firmly adherent mural thrombus, showing early organisation (see figs. 3–5). Silver technique revealed no spirochætes. *Spleen* much congested; excess of melanin pigment. *Brain:* sections from cerebellum, gyrus rectus, and thalamus revealed no abnormality. Unfortunately the rest of the brain was discarded before further sections could be taken.

DISCUSSION

Ransome et al. (1945) have suggested that some cases of arsenical encephalopathy are really cerebral malaria. Though the patient had previously had twelve attacks of malaria, the onset of symptoms shortly after an injection of neoarsphenamine, given at a month's interval after a previous course, is in keeping with arsenical encephalopathy (Rabiner et al. 1943). Congestive heart-failure was found as soon as the patient recovered from the encephalopathy. A cerebral vascular accident, due to meningovascular syphilis, is improbable, especially in view of the normal appearance of the brain post mortem.

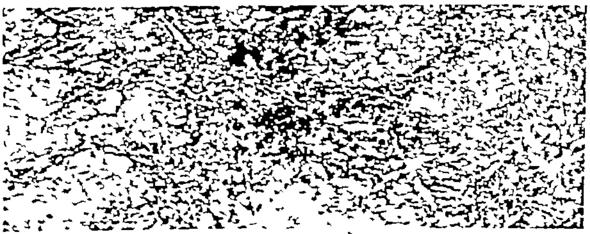

Fig. 4—Focus of fibrous tissue. (Mallory × 40.)

The most likely sequence of events therefore seems to be that at the same time as the encephalopathy developed there was acute focal necrosis of the heart muscle, neither process being sufficiently severe to kill the patient immediately. After regaining consciousness he lived seven months, during which the necrotic areas in the heart muscle became completely fibrosed. The persistent eosinophilia is of interest, as it is thought to have an allergic basis (Brown and McNamara 1940); no ca for it was discovered.

There was never any direct evidence of vitamin complex deficiency in this case. Since treatment w started exactly a month after the appearance of th chancre, and there was never any evidence of secondar syphilis (the patient was infected in Africa), the pos bility of syphilitic myocarditis (Warthin 1925) is remo

Brown and McNamara (1940) collected 7 cases o acute interstitial myocarditis following arsenical therap and added a case of their own; all these cases occurre in the course of exfoliative dermatitis and were rapidl fatal. They describe exudate, hæmorrhage, and minut foci of muscle necrosis, with heavy infiltration of whit cells, mainly eosinophils; the blood-vessels were normal, and the necrosis was not perivascular.

Smith and Furth (1943) describe 3 cases of fibrosis o the endocardium and myocardium ("Fiedler's myocarditis") in which there was gradually progressive congestive heart-failure of obscure ætiology for 8 years, 9 months, and 8 months respectively. The clinical, pathological, and histological findings were strikingly similar to those in the present case. A common feature was the great weight of the heart, which in the present case could presumably be accounted for by the large thrombus in the left ventricle and by hypertrophy of the severely damaged myocardium called upon to work for seven months. There was no history of any of these patients having had either syphilis or arsenical treatment, and in all there was evidence of long-continued dietetic insufficiency. Smith and Furth postulate vitamin-B complex deficiency as the probable cause; they review previously reported cases of Fiedler's myocarditis and suggest that the condition is probably a variant of beriberi heart.

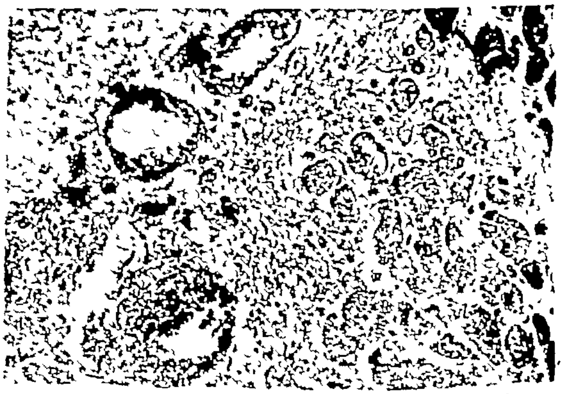

Fig. 5—Dilatation of blood-vessels within an area of scar tissue. (H. and E. × 250.)

In the nervous system the commonest findings in arsenical encephalopathy are small perivascular hæmorrhages, œdema, plugging of capillaries, and perivascular necrosis (Wilson 1940). There is also evidence of primary necrosis of nerve-cells; Rabiner et al. (1943) describe a case in which fatal cerebral symptoms developed after 'Mapharsen'; they found discrete acellular areas of focal necrosis, as well as diffuse necrosis with astroglial reaction, in the cerebrum. These lesions were distinct from the vascular lesions usually described. Lichtenstein (1942) describes primary cell degeneration, with proliferation of the astroglia, in cases of postarsenical myelitis.

Lydon (1944) argues that primary cellular damage, as opposed to vascular damage, is the essential lesion in arsenical encephalopathy. He believes that nerve-cells, being highly developed, are the most susceptible to damage, but thinks it possible that other tissues may be similarly affected; he describes changes in the liver in a fatal case, without jaundice, possibly due to arsphenoxide, 'Mapharside.' He draws attention to similarities between arsenical and Wernicke's encephalopathies, and suggests that vitamin B_1 is a reasonable prophylactic and therapeutic agent in both conditions. He suggests that "the administration of arsenic calls for excess of some other factor necessary for efficient cell metabolism."

Focal myocardial necrosis may evidently follow either arsenical therapy or chronic nutritional deficiency. Brown and McNamara (1940) suggest that in post-arsenical cases the lesion is a primary cellular necrosis; the findings in the present case appear to represent the end-result of such necrosis in a case which survived.

Severe arsenical reactions may be more widespread than is usually realised; further observation is required to determine whether there is any relationship between nutritional deficiency and arsenical reactions.

It is suggested that in fatal cases of arsenical encephalopathy organs other than the brain should be examined histologically more often.

SUMMARY

A fatal case of focal myocardial fibrosis is described n which the evidence suggests that the lesion was due o neoarsphenamine. The heart lesion manifested itself n the patient's recovery from arsenical encephalopathy.

My thanks are due to Dr. W. D. Forsyth, medical superintendent of Pinder Fields Hospital, and Dr. H. H. Moll, onsulting physician to the hospital, for permission to publish his case; Dr. J. D. Spillane for his opinion on the nervous esion; Prof. M. J. Stewart for his opinion on the slides and or reading the proofs; and Mr. R. J. Manby, of the University f Leeds, for the photomicrographs.

Medical Societies

LIVERPOOL MEDICAL INSTITUTION

At a meeting of the institution on Oct. 24, with Dr. G. F. **Rawdon Smith**, the president, in the chair, a symposium on the

Use and Abuse of Sulphonamides

was opened by Dr. **Douglas Riding**, who dealt with the subject from the biological and physicochemical aspects. While he appreciated the tremendous value of the sulphonamide drugs to the clinician, as a pathologist he was disturbed by the potentialities for abuse in the new chemotherapeutic agents. In spite of our imperfect knowledge of disease processes, immunology, and enzyme chemistry, intelligent use of the sulphonamides might well mean the difference between death and life for patients suffering from such desperate conditions as puerperal sepsis, pneumococcal infections in the elderly, and cerebrospinal fever. What he deplored was "unscientific, indiscriminate, and mass bombing of every inflammatory battlefield with the sulphonamides." He then discussed the chemistry of the sulphonamides, with particular reference to the changes in pharmacological action brought about by modification of the essential groupings in the sulphanilamide molecule. Speaking of specific metabolite antagonists, he remarked that one could hardly hope to dabble in the fields of pharmacology and chemotherapy without some knowledge of the effects of competitive and non-competitive inhibitors on the velocity of enzymatic reactions. "A sulphonamide drug," he concluded, "is a chemical key which fits many doors in the castle of metabolism. Make sure it is the dungeon and not the pantry door which you lock, and if you are doubtful about the door, keep the key in the bottle in your consulting-room!"

Dr. C. A. **Clarke** thought the sulphonamides were given far too often in undiagnosed cases. It was much more difficult to decide whether a sterile pleural effusion in a young adult was tuberculous if sulphonamides had been given. He reviewed some surgical conditions in which a penicillin umbrella was used, and mentioned the attempted prevention of recrudescences of rheumatic fever by giving sulphonamides during the winter months. He then referred to the administration of sulphadiazine to 75,000 people in a Mexican town, which speedily stopped an epidemic of cerebrospinal fever. In his opinion toxic reactions were rare provided plenty of fluids were given and courses limited to about a week. The routine administration of the drugs in the tonsillitis ward was dangerous because of the risk of agranulocytosis. The main future of the sulphonamides lay in prophylaxis; in the treatment of established diseases they would slowly be replaced by penicillin and other antibiotics.

Dr. A. O. **Ross** said that in venereal diseases sulphonamides were of value in the treatment of gonorrhœa, non-specific urethritis, chancroid, lymphogranuloma inguinale, and granuloma venereum, but had no lethal effect on *S. pallida*. Sulphathiazole was the sulphonamide of choice in the treatment of gonorrhœa in doses of 6 g. daily for five days. The urine should be alkaline and there should be a copious fluid intake. Minor toxic reactions, especially in private patients, were more common than formerly, and this was probably a sensitisation caused by previous improper administration for a trivial complaint. This militated against the effectiveness of the drug in more serious illnesses. Because sulphonamides substantially reduced the infective period of gonorrhœa, fewer cases than expected, pro rata with syphilis, had occurred in the last few years. It was regrettable that sulphonamide treatment of gonorrhœa was being ousted by the more effective penicillin, since the latter masked the possible coincident infection with syphilis. In the sphere of venereal diseases, the greatest abuse of the sulphonamides had been the irrational habit of prescribing them in subtherapeutic doses to women complaining of vaginal discharge, before establishing the diagnosis by laboratory methods.

The **President** expressed the opinion that pushing any drug to the patient's extreme discomfort in the way of depression and nausea was unjustified. In erysipelas the sulphonamides often gave dramatic results.

Dr. R. W. **Brookfield** recalled the teaching of the late Prof. Hill Abram that when once the indications for a drug were well established it should be given in full dosage to produce the optimum effect rapidly. This certainly applied in the case of sulphonamides. The doctor's confidence in using a drug was considerably increased if he were well acquainted with the possible toxic effects and their relative frequencies. While the danger of agranulocytosis had been rightly stressed, its frequency appeared to have been exaggerated, since in that gathering, representing many aspects of medical practice, no-one seemed to have seen a fully developed case of severe agranulocytosis definitely attributable to sulphonamides. Little stress seemed to have been placed on dermatitis due to sensitisation. This had been a problem of some magnitude in the Far Eastern theatre and many soldiers and airmen had been invalided home because of intractable dermatitis resulting from the external application of one of the sulphonamides. So serious was the problem that it was in general forbidden to exhibit sulphonamides externally and internally in the same subject. Possibly the severe reactions seen were largely conditioned by the effects of bright sunlight, since skin reactions did not seem to be nearly as common in this country.

Dr. **Lennox Johnston** maintained that the administration of sulphathiazole to all cases of "influenza"—a provisional diagnosis attached, in general practice, to almost all varieties of infections, many of which turned out to be acute bronchitis, incipient pneumonia, &c.—was invaluable in shortening the illness and incapacity. Except in doubtful cases of gonorrhœa in the female, as Dr. Ross had pointed out, it was advisable to give 5 to 6 grammes as early as possible, and before a final diagnosis could be made.

Dr. F. **Glyn-Hughes** did not think there was much danger of general absorption when a sulphonamide was applied locally, so long as it was incorporated in a cream with a 'Tylose' or similar base. Impetigo and all streptococcal infections of the skin responded very well to such treatment and he did not hesitate to reinforce the effect by giving the drug internally at the same time. He had seen only one case of agranulocytosis and this was sufficiently rare to justify publication. He agreed that penicillin was superior to the sulphonamides in sycosis and some other staphylococcal infections, but sulphathiazole cream was an excellent remedy. He had not had a fatal case of pemphigus neonatorum since using sulphonamides, and for the same reason gonococcal ophthalmia had lost most of its terror. Dermatitis herpetiformis could be controlled by sulphonamides, and many cases of pemphigus responded, at least temporarily, when all else failed. He had always regarded lupus erythematosus as a manifestation of streptococcal infection, and had found that most recent cases responded well to sulphonamide therapy, though he agreed that search for the focus of infection was necessary; he had seen recovery in 3 acute cases of this disease when a sulphonamide was the only drug used. As a routine all cases of erythema multiforme received the drug, and there was no better treatment.

Dr. G. Y. YARDUMIAN said that in general practice sulphonamides should be used as a prophylactic in many diseases before an actual diagnosis was made, perhaps not in full doses. This would raise the morale of patients to some extent, since many of them asked for these drugs. If and when the patient was sent to hospital the amount of drug given and the duration of treatment should be stated. Sulphonamides were most beneficial in lobar pneumonia, but though the temperature came down on the second or third day this did not mean that resolution had taken place, since it may be delayed. They were also very useful in puerperal fever and erysipelas. When the patient was under sulphonamide treatment other means of helping him must not be forgotten, and plenty of fluids, warmth, and rest in bed prescribed.

Dr. G. WILLIAMSON said that sulphaguanidine had relieved anxiety in cases of bacillary dysentery in a mental hospital. All cases with clinical indications—e.g., pyrexia, diarrhœa with blood and mucus—were given a full course and within 48 hours were relieved of symptoms. Laboratory confirmation was not waited for in clinically positive cases but was obtained at the first opportunity. It was preferable to get clinical improvement rather than wait for laboratory tests before starting sulphaguanidine treatment.

Reviews of Books

1. Penicillin: its practical application

Editor: Sir ALEXANDER FLEMING, M.B., F.R.C.P., F.R.C.S., F.R.S., professor of bacteriology in the University of London at St. Mary's Hospital. London: Butterworth. Pp. 380. 30*s*.

2. Penicillin: its properties, uses and preparations

Published by direction of the Council of the Pharmaceutical Society of Great Britain. London: Pharmaceutical Press. Pp. 199. 10*s*. 6*d*.

3. Penicillin in General Practice

J. L. HAMILTON-PATERSON, M.D., pathologist to Redhill County Hospital, Edgware. London: Staples Press. Pp. 95. 5*s*.

4. Practical Points in Penicillin Treatment

G. E. BEAUMONT, D.M. Oxfd, F.R.C.P., physician to the Middlesex Hospital; K. N. V. PALMER, M.B. Camb., M.R.C.P., acting medical registrar at the hospital. London: J. and A. Churchill. Pp. 16. 1*s*. 6*d*.

WITH the exception of the handbook prepared by the medical staff of 21 Army Group and a special number of the *British Medical Bulletin* (1944; 2, no. 1), both of which had a somewhat limited circulation, no convenient and selected summary of the many original papers on penicillin therapy has been published. The removal of restrictions on the sale of penicillin to doctors gives occasion for the appearance of these four books, each of which gives sound guidance to those whose experience with penicillin is limited.

The books all give clear directions on dispensing and storage, with indications as to how much latitude can be allowed, and the one prepared for the Pharmaceutical Society points out that recent batches of penicillin are more stable than those of two years ago but that the potency of any batch is only approximate. On the clinical applications of penicillin there is little disagreement between the books. More attention than seems deserved is given by all to continuous administration; while useful in hospital practice, this is not easy elsewhere and seems to be less used than it was two years ago.

In the first book, one chapter of which has appeared in THE LANCET (1946, i, 805), Sir Alexander Fleming has called on the services of many others who have contributed to our knowledge of the subject; the account of his discovery and its development, and the chapter by Mr. Porritt and Professor Mitchell, are outstanding. Each chapter has a well-chosen list of references.

Seldom has so much information been compressed into two hundred pages as in the second book. The chemical assay of penicillin, the many methods of oral administration, and the various regulations under the Therapeutic Substances Act are all discussed in detail. The principles rather than the minutiæ of clinical application are stated clearly and the book is informatively illustrated.

The authors of the two shorter books write on the practical applications of penicillin from their own experience. Dr. Beaumont and Dr. Palmer give admirable directions for the technique of intramuscular injection.

Human Biochemistry

I. S. KLEINER, PH.D., professor of biochemistry and physiology, New York Medical College. London: H. Kimpton. Pp. 573. 30*s*.

MANY books are now being written on the clinical aspects of biochemistry, and it becomes a task to choose a novel title from "clinical biochemistry," "biochemistry in or of medicine," "clinical pathology," and "clinical diagnosis by laboratory methods." This book with its original title is more biochemical than clinical, but a chapter on clinical applications of biochemical tests is informative and useful. The remaining 28 follow the orthodox order, discussing physical chemistry, protein, fats, carbohydrates, enzymes, hormones, vitamins, urine acid-base balance, and the like.

Biology of Tissue Cells

ALBERT FISCHER, director of the Biological Institute, Carlsberg Foundation, Copenhagen. London: Cambridge University Press. Pp. 345. 31*s*. 6*d*.

THIS imaginative and stimulating book on tissue culture should appeal not only to specialists in this branch of biology but to all who are interested in the physiology of growth. As the author states in the preface, "it does not pretend to be a monograph nor a textbook, but includes a collection of experimental data on the subject, arranged in their proper relation to the main problems of biology and physiology." For this reason the work is less technical and of much greater general interest than most books on tissue culture. It deals mainly with unorganised growth in vitro—with cultures of actively migrating and dividing cells which have lost their normal histological arrangement and functional activity. Dr. Fischer regards such cultures not as colonies of independent individuals but "as primitive cell states or organism-like systems." He records much fascinating information about the biology of these systems; the laws which limit and control their growth, the structure, behaviour, and especially the interdependence of their component cells, their nutritive requirements, and their senescence and rejuvenation. Only certain aspects of organised growth in vitro are considered. Although this part of the book contains some interesting suggestions and ideas, it is inferior to the rest; for the remarkable capacity of many tissues for almost normal histological and sometimes anatomical development is not sufficiently stressed.

The translation from the Danish is adequate and the meaning usually clear, though there are some small errors of idiom and grammar. The bibliography is incomplete and sometimes inaccurate, owing, no doubt, to war-time difficulties, and a larger index would have been welcome. These, however, are trivial flaws in an important and eminently readable

Vitamins in disorders of the circulation

During the time—nearly 20 years—in which Vitamins Ltd. have been working on nutritional subjects, dramatic advances have been made in the recognition of deficiency conditions and diseases, and in the appropriate uses of vitamin therapy.

In disorders of the circulation the effect of B_1, preferably with other factors of the B Complex, on certain heart conditions is well known. A combination of vitamins and minerals greatly helps the assimilation of iron in deficiency anaemias. The value of vitamin K in promoting prothrombin formation is perhaps not generally appreciated.

Condition	Indications	Therapeutic Agents
1. CARDIAC CONDITIONS. **(a) Beri-beri heart.** **(b) Congestive failure with oedema associated with mild degrees of vitamin B_1 deficiency.**	Vitamin B_1 is needed for both these conditions possibly in high doses.	**VITAMIN B_1 (Aneurin hydrochloride) Vitamins Ltd.** Ampoules : 10, 50 or more mg. daily. Tablets : 3 mg. twice or thrice daily. **BEFORTISS B Complex Capsules, Vitamins Ltd., or** **BEMAX** to supply the other factors of the B complex.
2. CIRCULATORY DISORDERS without congestive failure, e.g., Varicose veins.	Vitamin B_1 in high doses has been found to relieve pain.	**VITAMIN B_1 (Aneurin hydrochloride), Vitamins Ltd.** By injection or by mouth. 10 mg. or more daily.
3. BLOOD DISEASES. **(a) Anaemias.**	Iron deficiency anaemias are frequently complicated by vitamin deficiencies.	**COMPLEVITE** Tablets of 2 colours to be taken in equal numbers. One of each colour thrice daily provides : Vitamin A - 4,000 i.u. Vitamin B_1 - 0.60 mg. Vitamin C - 20.0 mg. Vitamin D - 300 i.u. Calcium - 160 mg. Iron - 68 mg. Iodine, Manganese, Copper } not less than 10 parts per million *at time of manufacture*
	The macrocytic anaemias such as Addisonian pernicious anaemia and sprue have been found in preliminary trials to respond to folic acid.	It is hoped that folic acid will soon be available in this country for therapeutic trial.
(b) Hypoprothrombinaemia. **Haemorrhagic disease of the new-born.**	The prothrombin is normally low for the first few days of life.	**VITAMIN K, Vitamins, Ltd.** One tablet (10 mg.) daily to the mother during the last month of pregnancy or every 6 hours if seen first in labour, or 5 mg. by injection to the infant.
OTHER CONDITIONS **Hepatic diseases obstructive jaundice.**	Low prothrombin is here associated with defective absorption of vitamin K from the absence of bile salts in the intestine.	**VITAMIN K, Vitamins Ltd.** One tablet daily with bile salts.
Ulcerative Colitis.	Where fat absorption is defective.	**VITAMIN K, Vitamins Ltd.** One tablet daily

Precedents

THE object of administration is to create conditions in which work can be done smoothly and well. That is indeed the main reason for forming the National Health Service. Like the autonomic nervous system of the human body, such a service should perform its administrative functions unobtrusively and without obstructing in any way the activities it exists to subserve. It is a means, not an end; and it will be a failure unless it proves itself a better means than those already used with partial success. The Government are rightly trying to improve on the empirical and haphazard organisation of the past; but the price paid for rationalisation would be too high if it led to the medical work of this country being run on bureaucratic lines. Mr. BEVAN has delivered the hospital service from the hands of local authorities, and there are grounds for hoping that the Ministry of Health, making more use of professional advisers, will try to avoid a stultifying control.[1] A special effort will, however, be needed to prevent the installation of bureaucratic machinery round the regional boards by which the hospital services are soon to be administered.

The task of each of these boards will be very big. In an address lately given as president of the Hospital Officers' Club, Mr. C. M. POWER has calculated that, if there are 20 regions, each board, serving an average of 2 million people, will have 125 hospitals (not counting mental institutions) with 30,000 beds and a staff of 15,000, and will dispose of some £6 million a year. To cope with these duties it will require, he thinks, at least five committees—finance; staffing; planning; supplies and equipment; building and establishment—and also a number of subcommittees dealing separately with such subjects as tuberculosis and nursing. It is obvious that, if the members of the board and its committees (who will be unpaid) meet only occasionally, much responsibility will rest on its officers; and unless the right arrangements are made from the start, there is grave risk of these officers developing a bureaucratic outlook and procedure which would offset the benefits obtainable from planning the regional service as a whole

In an article[2] which deserves further attention, a correspondent has pointed out that there are two possible lines of development—two conceptions now competing for supremacy:

> "On the one hand, we have the comparatively simple 'service' conception of the regional organisation, with departmental officers and staff, each possessing their defined sphere of responsibility, directing and inspecting the various departments of hospital activity. Thus, to take one or two examples at random, we should have a regional nursing officer responsible for the standard of nursing throughout the hospitals, without whose assent a matron would be foolish to venture upon any innovations in nursing technique or organisation. We should have a regional financial officer, without whose blessing no hospital committee would care to incur expense for which there was no precedent. We should have, too, a regional architect, to whom projects would stand referred for translation into plans and estimates."

While admitting the many advantages of such a scheme our correspondent felt that it would raise the status of the regional officer at the expense of the people managing the hospitals, who will never pull their weight unless they have scope both for initiative and, in moderation, for mistakes. "If these people begin to feel that wisdom lies not in making their own decisions but in ensuring that their activities will commend themselves to the regional officers heaven help us." The alternative which he proposed would reproduce a striking feature of the sector organisation of the E.M.S., where authority was vested in professional personnel—medical, nursing, and administrative—who themselves already occupied posts of responsibility at the principal hospitals concerned: he would make it a rule that "no-one shall be appointed to a post carrying regional authority who does not already and concurrently hold a 'key' position in his or her respective sphere." This, however, is not enough by itself; and his complementary suggestion is that the regions should adopt the practice of King Edward's Hospital Fund whereby, on major issues, accredited representatives of the hospitals always have an opportunity to meet the appropriate subcommittee of the fund. He recommends the principle that "whenever questions of policy arise on which opinions may differ, decisions shall be reached, not by an official applying to the papers on his desk criteria of some central policy, but always in discussion across the table with those responsible for the execution of the project." The Nuffield Provincial Hospitals Trust makes use of the same excellent method.

There remains the problem of the constitution of the boards and the way in which professional opinion can best be presented to them. Elsewhere in this issue the same correspondent, quoting the experience of voluntary hospitals, argues that the views of the profession will be most helpful to the board if they come in the form of considered recommendations from an advisory committee. He believes that the presence of too many doctors on the board itself—speaking perhaps discordantly—might actually weaken the professional voice in its counsels, which could or should be expressed most strongly by a medical advisory committee through its chairman and secretary Moreover, if the board itself, losing sight of its proper functions, were to assume those of a medical advisory committee, its essential decisions would probably be taken by an inner ring. These decisions are ultimately financial. What the board has to do is not to treat patients but to create conditions in which others can do so: much of its time will be taken up with non-medical matters such as the employment of lay staff, the purchase of equipment and stores, and the distribution of money; and there is substance in Mr. POWER's plea that—whether he is a doctor or a layman—the primary qualification of its chief executive officer, or secretary, should be that he is an experienced hospital administrator. On the other hand, since the board's labours are useless except in so far as they promote the recovery of patients, it must at all times have the aid of a medical committee well qualified to speak on the needs of the service, on the assignment of tasks, and on the relative value of possible developments, as well as on the recruitment, appointment, and working conditions of medical staff. The secretary of this committee must of course be a doctor, but our correspondent would give him a seat on the board rather than make him the senior medical member of its secretariat. While it is evident that the board must have a paid staff, we can imagine nothing more harmful than a hierarchical system in which the doctors and nurses in the hospitals came to regard a regional official as their professional chief.

---

[1] See *Lancet*, Oct. 19, p. 567.
[2] *Ibid*, July 27, p. 137.

The voluntary hospitals, in eschewing hierarchy, have produced some remarkably sound precedents, and we trust that Mr. BEVAN's promise to "decant the best experience of the voluntary hospital administration into the future hospital service" will apply to principles as well as to persons.

Progress with Folic Acid

IT is now clear that folic acid will take its place among the vitamins. Like other vitamins, it has many natural sources and exists in several, probably closely related, forms. The name was originally given to an almost pure chemical substance isolated from spinach[1]; it is found in many other green leaves, including grass, and in mushrooms, liver, and yeast. The folic-acid compounds have been studied during the last decade under several names, for the following are now known to be folic-acid variants—vitamin M, deficiency of which causes a pellagrous syndrome of anæmia, leucopenia, diarrhœa, and mouth lesions in monkeys; vitamin B_c, deficiency of which causes a nutritional anæmia in chicks; vitamins B_{10} and B_{11}, responsible for growth and feather development in chicks; and the "eluate factor" (from liver) and the "*L. casei* factor," both essential for the growth of *Lactobacillus casei* and *Streptococcus fæcalis* R. It is the *L. casei* factor from liver that has been synthesised and whose constitutional formula has been established; the name "pteroyl glutamic acid" has been suggested for this folic acid, which will, so far as is known, produce all the effects of the other forms. The *L. casei* factor from yeast differs only in the number of glutamic-acid molecules; the relations of the other factors have not yet been worked out.

With its wide distribution, folic acid must be present in any mixed diet, and no instance of natural folic-acid deficiency in man has been described, though deficiencies have been artificially brought about by giving specially purified diets. Rats, and probably other mammals, are not dependent on food intake for their supplies of folic acid, since, as with vitamin K, they can synthesise it in their intestine. The addition to the diet of a sterilising sulphonamide-like sulphasuxidine prevents such synthesis, and this was how NELSON and ELVEHJEM[2] produced the folic-acid deficiency syndrome in rats—granulocytopenia and lack of growth—and corrected it by giving folic-acid concentrates. Leucopenia, especially lack of polymorphonuclears, is the outstanding hæmatological effect of artificial folic-acid deficiency in monkeys and rats, and when folic acid was first given to patients with nutritional anæmia it was with the idea of correcting the leucopenia. This it does; but the effects on the anæmia were equally startling and have now overshadowed the leucopoietic properties.

The place of folic acid in the treatment of human disease is beginning to take shape. It is of no value in iron-deficiency anæmia, in anæmias characterised by hypoplasia or aplasia of the bone-marrow, in leukæmias, and in a still indefinite group of other anæmic conditions that yet respond to liver extracts. Folic acid is a powerful therapeutic agent in addisonian pernicious anæmia, nutritional macrocytic anæmia, sprue, and the macrocytic anæmia accompanying pellagra; success has also been reported in cœliac disease.[3] The results are variable in refractory megaloblastic anæmia, including non-tropical sprue, and in anæmia secondary to cirrhosis of the liver, but it is worth a trial in these cases. There is no convincing evidence that it has any effect in idiopathic agranulocytosis, or in the agranulocytosis or neutropenia secondary to dosage with drugs like the sulphonamides or thiouracil; in nutritional anæmia a leucopoiesis occurs as part of the general hæmopoietic recovery. Finally, there is the report of CARRUTHERS[4] from India that in patients with chronic diarrhœa (not dysenteric) and microcytic anæmia folic acid will relieve the diarrhœa without affecting the anæmia; and SPIES has noted that in sprue the radiological pattern of the bowel returns to normal and the excessive irritability disappears when folic acid is given.

The dosage of synthetic folic acid is being rapidly worked out. It can be given by mouth or parenterally dissolved in disodium phosphate. For pernicious anæmia the oral route is adequate; 20 mg. is given daily in the relapse phase and this dose is maintained until remission is well established, when it is reduced to 10 mg. daily or less. DOAN,[5] and DAVIDSON and GIRDWOOD,[6] report suboptimal results with doses of 2–10 mg. daily. For maintenance, DOAN reports that the dose needed varies from 40 mg. a week to 20 mg every third week; with this régime minor neurological signs improve and no case has so far developed signs of involvement of the spinal cord tracts. Good results have been reported with single large doses of 150 mg. parenterally or 400 mg. by mouth; these produce a rapid reticulocytosis but are probably unnecessarily large. In nutritional anæmias, 20 mg. daily seems adequate, and the same dose is effective in sprue; the parenteral route has some advantage in the early part of the illness. The general conclusion is that 20 mg. is an effective daily dose for these anæmias and larger doses should not be given; folic acid is not easy to prepare and supplies are unlikely to be plentiful for some time. In the refractory types larger doses are in order, but there is little information yet; according to DOAN the maximal permissible intravenous dose is 150 mg., since larger doses may cause histamine-like vasomotor disturbances. Doses up to 400 mg. have been given by mouth without distress.

A comprehensive review of the development of knowledge about folic acid has been published by BERRY and SPIES,[7] and another appears in the UNRRA *Bulletin.*[8] The latter remarks that folic acid

is valuable "in the treatment of anæmia, particularly macrocytic anæmia, irrespective of the clinical classification." But this is scarcely true: if anæmias are classified on a basis of clinical signs plus the type of morbid erythropoiesis, on a scheme like that put forward by ISRAËLS[9] in 1941, then it is clear that all anæmias that have so far been shown to respond to folic acid fall into ISRAËLS's "type 1," in which there is failure of maturation of pro-erythroblasts and deviation to megaloblastic erythropoiesis, anæmias in the other types do not respond. The evidence so far suggests that a response from folic acid can only be expected in patients whose sternal bone-marrow reveals definite megaloblastic change, and classification on these lines has, in fact, been followed by all clinical workers with folic acid. In nutritional anæmias this classification is particularly necessary, since non-megaloblastic macrocytic anæmias are common, and there is no evidence that they respond to folic acid.

Folic acid is still regarded as an enzyme or co-enzyme in the system that produces the liver principle. DAVIS[10] has shown that folic acid will increase the serum cholinesterase and will restore the blood-count of dogs rendered anæmic by feeding with choline chloride; the application of this information is not very clear, and there is no reason to suppose that the choline anæmia of dogs is in any way related to human megaloblastic anæmias.

The clinical research on folic acid has been of a high standard: cases have been carefully selected, proper criteria decided on beforehand,[11] and multiple therapy avoided; all of which makes for progress and firm assessment of results. The advent of such a potent hæmatinic agent as this makes it ever more necessary to observe the maxim: "Diagnosis before treatment."

Oiled Bed-linen

DUST in coalmines and in cotton-mills has long been recognised as a cause of chronic respiratory diseases on which may be superimposed such bacterial infections as bronchitis, pneumonia, and tuberculosis. But dust in the home, in the office, and particularly in the hospital ward may also be a carrier of disease. Many respiratory pathogens—hæmolytic streptococci, diphtheria bacilli, pneumococci, probably tubercle bacilli, the viruses of smallpox and psittacosis, and certain rickettsiæ—have considerable viability outside the body and may be recovered from the clothing and bed-linen of affected patients and from the floor dust in the environment of human or animal carriers. Until recently the clinician was so imbued with the Flügge doctrine of the spread of respiratory infection directly by droplets that he was unwilling to believe in a more indirect spread by bacteria-laden dust. Indeed the evidence in favour of dust-borne infection is still largely circumstantial, although numerous clinical records have incriminated infected dust as the source of streptococcal sore throats, "Q" fever, and psittacosis.

The part played by a particular agent in the spread of infection can be assessed by eliminating the agent from one group of mice or men at risk while allowing it to persist in a control group. Dust in mines has been partially controlled by wet drilling and spraying Its control in the home or in the hospital ward is an entirely different problem. During the late war this problem was ardently and ably tackled by VAN DEN ENDE and his colleagues who showed that floor dust can be trapped by treating wooden or linoleum floors with spindle oil—a crude petroleum oil which, when sparingly applied to the unwaxed surface at intervals of 4–8 weeks, reduced by 80–90% the bacterial content of the air during sweeping or other activities. Later they devised a method for oiling sheets and blankets with an oil-in-water emulsion which retained over 90% of the bacteria-carrying particles ordinarily released during bed-making. At this stage the coöperation of the British Launderers Research Association was enlisted and resulted in an improved technique for oiling bed-linen on a large scale in hospital laundries.[1] The principle of the method is that oil drops are positively or negatively charged by the addition of cationic or anionic wetting agents which fix any desired amount of oil in the woollen or cotton fabrics This method, used by WRIGHT and her colleagues[2] in a measles ward where streptococcal cross-infection was rife, caused a remarkable reduction in both latent and clinical infection contrasted with an untreated ward: in the control ward there was 73% streptococcal cross-infection and 14·3% acute otitis media, while in the treated ward the corresponding figures were 18·6% and 2·8%.

The scene shifts to America ROBERTSON and his associates,[3] impressed by the part which infected dust apparently played in the spread of infection in army barracks and hospitals, began in 1943 to study the problem of dust control along lines similar to those followed by the English workers. First they confirmed that certain bactericidal substances and water-soluble wetting agents when applied to blankets had no bactericidal or adsorptive action on infected dust. Next, using a purified mineral oil ('Fractol A') as base, they found two substances which were particularly effective as wetting and fixative agents. The first of these, triethanolamine oleate, was finally discarded after field trials, because the oil tended to separate on standing, while the oil content of treated blankets was uneven, varying from 1% to over 5%, at which level there is a considerable fire hazard. The other emulsifying agent 'Triton E,' a substituted phenyl ether of polyethelene glycol, gave in a proportion of 13 parts to 87 parts of the oil a stable paste which, being non-ionic, was not neutralised by mixture with soaps or acids and was not affected by variations in the pH or hardness of the water. This oil emulsion, added to the last water rinse in the washing machine, is equally effective for the oiling of woollen and cotton goods, is cheap and easy to apply, and is non-irritating to the skin; in fact the whole procedure seems to be remarkably free of pitfalls. The fact that oiled blankets retain their dust-holding property after a number of washings suggests that the oiling of new blankets by the manufacturer might become a routine. The 2–4% of oil in the blanket cannot be detected by touch, and tests have shown that oiled blankets are likely to be warmer than unoiled blankets and

to last at least as long. Extension of the oiling to surgical dressings, wearing apparel, and other fabrics may follow.

Although the American workers have confirmed the value of oiled bed-linen for the control of streptococcal infection in hospitals,[4] they have been disappointed with the procedure for the control in barracks of non-bacterial "catarrhal fever," which occurred regularly as a winter epidemic among recruits.[5] The most likely explanation of this failure is that these non-specific upper respiratory infections are transmitted by direct contact or by droplet nuclei rather than by contaminated dust. There is good epidemiological evidence that certain virus infections, such as measles and chickenpox, are spread by droplet nuclei; and in the case of catarrhal fever the Americans found that double-bunking in barracks, which reduced considerably the opportunities for direct-contact transmission, also reduced by a half the epidemic incidence of the disease. Even with streptococcal infections, where the existence of secondary reservoirs in dust is well established, little is known of the relative importance of dust compared with droplets and droplet nuclei in the spread of the disease. However, the evidence incriminating dust in the spread of bacterial infections has been steadily accumulating, and it seems that the oiling of bed-linen by hospitals for children and for tuberculosis and other infectious diseases is both hygienic and practicable.

Annotations

PATIENCE REWARDED

THE appearance within a few weeks of four books designed to give guidance in the uses and hazards of penicillin is the epilogue of perhaps the most interesting drama of modern therapeutics. From now on neither pharmacist nor physician has any excuse for misusing penicillin. Supplies are ample; the price is moderate; the potentialities that we know are unlikely to be extended greatly, though there will still be advances—for example, in methods of prolonging the effect of a single dose and in oral administration.

In retrospect we can now consider whether this drama has been played well or ill. The preface to the monograph on penicillin published under the ægis of the British Pharmaceutical Society (reviewed elsewhere in this issue) suggests that harm has resulted from the conditions of secrecy and scarcity under which the earlier scenes were acted. It is a point worth consideration, since every day so many in so many laboratories seek out therapeutic agents as yet unknown to us. What made the early history of penicillin so different from that of many other drugs? Conceived—if Sir Alexander Fleming will forgive us—in obscurity, it was a weakly child saved only by parental devotion until its godfathers in Oxford gave it strong limbs and higher potencies. Transatlantic migration gave it fecundity (and, we must add, a split personality, since there is no longer one penicillin but many penicillins). Meanwhile it had won its spurs in the Radcliffe Infirmary and for three years slew innumerable staphylococci (and other pagans) from the Solomon Islands to Seattle. No hero of Christendom ever served such an apprenticeship of arms before he was released from tutelage. His powers were measured, his feats catalogued, and his misdeeds, few though they were, corrected. He has now stepped into the world, a force for good at the service of those who require his aid.

Would as much benefit have been gained had penicillin been released for general use in, say, 1942? The question is admittedly an idle one, since peace and deep culture were both necessary before this drug could be available in quantities sufficient for all. Other drugs have been subject to intense therapeutic trial before they have been released on the open market. Manufacturers have coöperated nobly, and the medical world hears of the successes and not of those which have been consigned to the dustbin without demur when they have been shown to be either valueless or dangerous. Other drugs have resulted from coöperative endeavour where thoughts of pecuniary reward have been of secondary importance or less than that. But if we may judge from the history of the sulphonamides and their successors, penicillin has been the gainer from its slower development. Endocrinology likewise provides object lessons of the dangers of uncontrolled trial of therapeutic agents whose possible effects are scarcely known. Penicillin, it is true, seems to have few evil habits, but it is hard to believe that its history would have been such a continuous story of success if it had been thrown early on the world and lacked the arduous and painstaking nurture that it received from so many disinterested minds in this country and America.

Some of us remember with equal pride and shame a meeting of the section of pathology of the Royal Society of Medicine at St. Mary's Hospital in the early thirties when Dr. Fleming showed some pictures coloured with chromogenic bacteria and a plate on which some staphylococci had been inhibited by a mould. After all, we too got our plates contaminated and we did not boast about it. We were very young.

PURIFICATION OF TETANUS TOXIN

THE preparation of the convulsive constituent of tetanus toxin in crystalline form, as reported[1] from Western Reserve University, U.S.A., is a step of outstanding importance towards the interpretation of the action of tetanus toxin used in the form of crude filtrates. The crystalline toxin is protein in character without a carbohydrate constituent and is apparently free from thiol groups. It has about 50,000,000 lethal doses for mouse, and about 3500–4000 flocculating units, for each mg. of nitrogen, the degree of purity being nearly 600 times that of the parent toxic filtrate. The basis of the method of preparation is precipitation at accurately controlled hydrogen-ion and salt concentration by methyl alcohol at temperatures of $-4°$ to $-5°$ C. The crystals tend to disintegrate at temperatures above $-4°$ C, creating considerable difficulties in handling the material. So far no electrophoretic sedimentation or solubility analyses have been published, but the fact that three recrystallisations gave no significant change in the flocculation value suggests that the material is a single protein.

Tetanus toxin has perhaps been the most troublesome of all toxins that the immunologist has to deal with. It has been known for some time that filtrates differ qualitatively in their properties,[2] as determined, for example, by the ratio of lethal doses in different animals, though the antitoxins produced by the injection of different filtrates are apparently identical.[3] The isolation of a pure crystalline toxin from such filtrates may well throw light on these and other, probably related, difficulties which have arisen in the titration of tetanus antitoxin; for in the crude filtrates it is possible that

other substances modify the course of the reaction between toxin and antitoxin and between toxin and tissue cell. The obscure problem of what happens when toxoiding occurs will also be brought definitely nearer solution now that the reaction can be followed on the single chemical substance instead of the mixture of substances present in the filtrate. It is to be hoped that this method will be successfully applied to other toxins, particularly to diphtheria toxin.

It is curious that the method of precipitation of protein with alcohol in the cold, first used some forty years ago by Mellanby[4] and now becoming of increasing importance, should have been neglected for so many years. The probable reason of its neglect was that the proper application of the method needed rigid temperature control at low temperature, and it was not till the war and American chemical engineering combined to provide facilities that Cohn, working on the fractionation of human plasma, was able to work out the conditions for successful large-scale handling of such processes.

CHILD HEALTH

> "Primary responsibility for the health of their children must continue to rest with parents and they should regard members of the health services as agents helping them to carry out their duties and not as authorities taking the responsibilities off their shoulders."

THE pædiatric committee of the Royal College of Physicians put this disclaimer on the first page of their final report,[1] but it does not prevent them considering responsibly and fully the duties of doctors to children. The principal means of promoting child health and welfare, they consider, are good food and good home and social conditions for both the child and the pregnant woman; proper training of doctors and nurses in the hygiene and feeding of children; education of parents and children in health; and the provision of good medical treatment services. The long-term policy, they hold, should be to make the general practitioner primarily responsible for the care of the child, in both prevention and cure of disease, since he is best fitted to give this service in the home. If his skill is to be adequate, pædiatrics should be a major clinical subject in his training, as recommended in this committee's interim report.[2] Where a health centre is established, one or more of the doctors on the staff should be specially interested in and trained in child health. Until enough well-trained doctors are available, those undertaking child-welfare work should have postgraduate training in the basic principles of public health, such as is contained in the course for the new certificate in public health, as well as postgraduate experience in the prevention and treatment of illness in children. Not only general practitioners but hospital pædiatric physicians should give some part of their time to preventive work, attending clinics, nurseries, and schools for the purpose; and, conversely, doctors employed whole-time by local authorities to do preventive work should be attached to a hospital and should spend, say, a fifth of their time in curative work. This general linkage of clinical and preventive work can be achieved, the committee think, if interchanges of staff are arranged between children's hospitals and departments and the local-authority health services, which will ultimately be staffed by general practitioners. In the meantime, since hospital pædiatricians are scarce, it may be possible to give special hospital training in pædiatrics to a proportion of full-time assistant medical officers of health, returning them to their areas to do both curative and preventive work.

In future it seems likely that all school health work will be carried out by one of these three types of doctor, which means that school clinics will become closely associated with children's hospitals, as they should. Child health visitors, able to nurse the sick child and teach child health, should do nursing and preventive work in clinics and schools.

They consider that hospitals need rebuilding and regrouping, and that both equipment and staff—nurses as well as doctors—could be improved. At present most hospital beds for children are not under the care of trained pædiatricians, and only about 40% of the sisters in charge of such beds have been trained for the State qualification in children's nursing. Since acutely ill children stand transport badly, they should have beds in their own district, while beds for long-term cases should be in hospitals outside the town, though within range of visiting parents. Eye, skin, rheumatic, and orthopædic conditions, the committee think, should be treated in special units housed in pavilions in the grounds of long-term hospitals; and general children's hospitals should have wards for infectious diseases, while fever hospitals should have general wards.

Much thought has been given to university teaching. The committee suggest that, in addition to the university departments of child health now developing, special departments closely connected with the universities might be established in non-university centres, each of which would guide pædiatric work in its own region.

Finally, to achieve integration of all child-health services, they suggest that a joint committee should be set up in each region, consisting of members of the university department of child health, and the regional and local-authority officers engaged in child-health work. This body would advise on all matters to do with child health, and would link the hospital service of the region with the services provided in each major local-authority area. They suggest, too, that under the National Health Service there should be a standing subcommittee on child health of the Central Health Services Council. The Royal College of Physicians, it is strongly recommended, should also have a standing committee on pædiatrics capable of advising on all such matters.

WORLD HARVEST

WITH the gathering of this year's harvest in the Northern Hemisphere we can see roughly how much grain the world has in hand for the coming year. China seems to be better placed than was expected, though there may be large areas of scarcity; but in India and parts of Malaya the situation is likely to remain fairly critical, and even allowing for local shipments of rice the deficit countries of the Far East will still need to import nearly 10 million tons. Russia may have a million or so tons of surplus grain for export to countries within her zone of influence. The deficiency in Europe is estimated at 12 or more million tons; England will have to import 4–5 million; and an additional 2 million will probably be needed for various other regions, including South Africa and some of the poorer South American countries. The total needs of the grain-deficit areas in the coming year will thus amount to almost 28 million tons. But though the North American harvest has been good, the exportable surplus from Canada, the United States, Argentine, and Australia is unlikely to exceed 22–23 million tons, and may be less.

These figures are given in the October issue of the *Nutrition Bulletin*,[1] which emphasises the necessity of

(1) preventing needy communities from eating their new supplies too rapidly; (2) preventing a bottleneck in transport if shipping passes altogether out of Government control; and (3) diverting coarse grains from the feeding of livestock in the New World to human consumption in the Old World. With the operations of UNRRA coming to an end, there is no international body empowered to purchase large stocks of foodstuffs; the International Emergency Food Council, established last May, can only assess the situation from time to time and submit recommendations, and the major countries will naturally tend to pursue the policies that seem best suited to their own interests. UNRRA will be missed because it protected the poorer liberated countries by preventing their wealthier neighbours from acquiring excessive supplies on the world market; and the richer countries seem likely to derive additional advantage from last week's decision of the American Department of Agriculture to abandon the bulk purchase of food for export.

The purpose of the World Food Board, advocated by Sir John Boyd Orr at the September meeting of the Food and Agriculture Organisation in Copenhagen, would be to make overseas farmers aim at a record harvest by guaranteeing the purchase of any surplus at a fixed price. This plan was rejected at last week's Washington meeting by the United States representative, who suggested, no doubt with the International Trade Organisation in mind, that importing and exporting countries can better solve their problems through multilateral agreements covering specific commodities. The American rejection has caused disappointment in this country, some holding that there is now little chance of whole-hearted American participation in an international attempt to fight the world food shortage; but Sir John Boyd Orr himself has since made it clear that his plan was simply put forward for discussion, and that the agency he has in mind would be composed of representatives not only of the F.A.O. but of the International Bank and other bodies. He insists that his suggestions are complementary to the aims of the International Trade Organisation, and he is confident that a satisfactory scheme will be evolved.

DERMATOLOGY

THE views expressed early this year[1] by the Royal College of Physicians committee on dermatology[2] are carried further in a final report presented to the college last week. The concluding recommendations chiefly concern the training of undergraduates, the selection and training of future consultants and specialists, and refresher courses for medical practitioners.

Skin diseases account for some 6% of the work of general practice, and in industry occupational dermatitis wastes more time than any other form of industrial disease. Teaching of the undergraduate should therefore be such as will enable him, after qualification, to increase his knowledge and to correlate cutaneous signs with *constitutional* disorders. To meet the Goodenough Committee's wish[3] that medical training should be a smooth and logical development, the committee recommend that in the preliminary year of study he should acquire some knowledge of the common animal and vegetable parasites which attack man, and that, when studying physiology, his attention should be drawn to the importance of the physiological actions and reactions of the skin in the maintenance of health. Dermatological cases should be demonstrated to students during the introductory course in which they first approach clinical work, and systematic teaching in dermatology should be incorporated in the general course of medical teaching before the student becomes a clerk in the skin department. As a clerk in that department, he should attend at least twice a week for three months, and should study inpatients as well as outpatients. To this end, and in view of the importance of dermatology in the health service of the country, 5% of the total beds in any teaching centre should be allotted to skin disorders; or, if this is impracticable, the beds should be provided in an associated hospital. Also the committee want teaching hospitals to have dressing-centres where the patients would attend for regular treatment. This would save much of the waste of drugs through faulty application at home; it would enhance the therapeutic efficiency of the departments; and if (as is proposed) each student worked there as dresser, the centres would provide valuable experience.

About 50 men are now in training as registrars or assistants in the dermatological departments of teaching hospitals, and it is suggested that clinical and laboratory facilities for basic training should in future be provided for 15–25 each year. As formerly many dermatologists had to supplement their basic training at institutions abroad, the recent proposal for the formation of a dermatological institute in London is welcomed by the committee, who emphasise however that the ancillary departments and staffing of such an institute must be of the highest order, and that in order to give equal opportunity to all suitable candidates there will have to be financial support for graduates in training. A would-be consultant in dermatology should, they think, obtain a diploma or degree comparable to the M.R.C.P. Lond. and should have a university degree, and he should have studied for five years after medical registration. During these five years he should first hold a resident or non-resident appointment in the department of general medicine for a year; then he should spend a further year in the pathological and bacteriological departments; and thereafter he should work as an assistant or registrar in the dermatological department of a teaching hospital, and should also study ancillary subjects, such as venereology, actinotherapy, radiotherapy, zymotic diseases, and industrial medicine. After this a period of research and study abroad is desirable. It is hoped that eventually all skin departments in hospitals—even in the smaller non-teaching hospitals—will be staffed by fully trained dermatologists. Meanwhile it will of course be necessary to employ many whose training has been less comprehensive, and the vacancies could be filled by graduates who have been practising dermatology for a reasonable time and who hold or have held hospital appointments in dermatological departments. Experience as a dermatological specialist in one of the Services will of course be a strong recommendation. For general *practitioners* it is suggested that courses should be offered by the institutions providing this type of postgraduate study—e.g., municipal hospitals and non-university centres. Oddly enough, no stipulation is made that these courses should be supervised by consultants or senior specialists; yet obviously the instruction of practitioners should be impeccable.

Finally, it is proposed that the Royal College of Physicians should set up a Dermatological Board, including representatives of the British Association of Dermatology and Syphilology and the professorial staffs of the dermatological units. The duties of this board would include the recognition of hospitals at which postgraduate training in dermatology could be undertaken, and decisions concerning the suitability of candidates for appointment to hospital staffs. But, for the present at any rate, it is not recommended that either the college or the board should create a diploma in dermatology.

TRIALS OF WHOOPING-COUGH VACCINES

IN conjunction with the medical officers of health of anchester, Tottenham, and Wembley, the Medical esearch Council are initiating field trials to assess the rotective value of pertussis vaccines. In these three reas, parents of children aged 6–12 months have been nvited to help by enrolling their children for inoculation within the next few months. The volunteer children are o be divided into two groups, one group receiving pertussis vaccine and the other group—the controls—an anticatarrhal vaccine. Details of the investigation are so arranged that no-one engaged in the day-to-day work of inoculation and subsequent follow-up will know which vaccine any particular child has received. The children are to be visited every month by specially appointed health visitors, who will take specimens for bacteriological examination from any child with a suspicious cough, and arrange for one of the doctors taking part in the trial to visit the child and make a clinical diagnosis. The results will be assessed at the end of two years.

In the propaganda to parents—mainly by pamphlets and personal visits by health visitors—all the details are fully explained. The enrolment of children has so far been encouraging. All general practitioners in the areas concerned have had a letter telling them about the investigation, and they have been asked to report any suspicious coughs in children included in the trial. The doctor will then be told immediately if whooping-cough is diagnosed by the special investigators.

In the first place American vaccines, as prepared for Professor Sauer, of Evanston, and Dr. Pearl Kendrick, of Grand Rapids, both of whom have claimed success with prophylactic vaccination, are to be used. The American vaccines have been chosen for trial because previous results obtained in controlled trials with a British vaccine had proved disappointing. If these prove satisfactory, further trials will be made with new British vaccines.

ANÆSTHESIA

ON Oct. 30 the Princess Royal unveiled at the Royal College of Surgeons a memorial with the following inscription:

> This tablet was erected in the Royal College of Surgeons of England by the Association of Anæsthetists of Great Britain and Ireland to mark the centenary of the first operation under anæsthesia in this country and to keep the memory of four British pioneers whose names will be held in honour from generation to generation
>
> HENRY HILL HICKMAN
> JAMES YOUNG SIMPSON
> JOHN SNOW
> JOSEPH THOMAS CLOVER

In his speech on this occasion Dr. A. D. Marston, president of the association, pointed out that two of the pioneers thus commemorated were members of the college, while one was a fellow; and he announced that a medal named after John Snow is to be awarded from time to time for signal service to the specialty. As recorded on p. 702, Dr. Marston presided next day at a centenary dinner held in Lincoln's Inn.

The main events and personalities of the story of anæsthesia were again reviewed in a fascinating address, delivered after a reception at the Royal Society of Medicine on Nov. 1, by Dr. Stanley Rowbotham, president of the section of anæsthetics. It was surprising, he said, how long man suffered pain without making purposive efforts to relieve it; how long he had the means at hand but did not use them; and how long their use, once discovered, was opposed. Beginning with Sir Humphry Davy, who in 1799 stopped toothache with nitrous oxide and suggested that this gas might "probably be used with advantage" in surgical operations, he spoke of the experiments begun in 1824 by Hickman, the first man to conceive of an anæsthetic state, and passed from the observations and practice of Faraday, Long, Clarke, and Wells to those of Morton, who by his enterprise and determination made anæsthesia an accomplished fact. Having shown a portrait of the first child delivered under an anæsthetic, who was of course baptised Anæsthesia, Dr. Rowbotham noted how the popularity of ether, chloroform, and nitrous oxide waxed and waned as new methods of giving them were devised. In 1884 local anæsthesia was introduced on the Continent, and it is still largely in use there because of the comparative scarcity of specialist anæsthetists. (Sir Gordon Gordon-Taylor expressed the opinion that surgery is not going to advance much further in European countries without an advance in their methods of anæsthesia.) Then came intraspinal, endotracheal, and intravenous techniques, basal narcosis, and curare.

The Society of Anæsthetists, parent of the R.S.M. section of anæsthetics, was founded in 1893, the first society in the world for the special discussion of the subject. The Association of Anæsthetists dates from 1932; the diploma in anæsthetics, which Dr. Rowbotham thinks has done more than anything else to raise the standard of anæsthetic practice, from 1935; and the Nuffield chair at Oxford, creating a great centre for teaching and research, from 1937. Contrasting the operating-theatre of 100 years ago with that of today, he was astonished at the difference already made in the removal of pain. What other branch of medicine could claim such progress in a century? "May the next hundred years be as prolific in its gifts to mankind."

TOO WIDE A GAP

OUR suggestion on Oct. 26 that, in an experimental training school for nurses, a medical dean of nursing might be appointed has proved unwelcome both to Miss Houghton (p. 693) and to the *Nursing Times* (Nov. 2, p. 836). The dismay which this proposal, made in full sympathy with nursing interests, has evoked is some measure of the gap now dividing the two main professions responsible for the welfare of the patient. Perhaps it will reassure our nursing colleagues if we add that in medical schools we should like to see a senior member of the nursing staff appointed to ensure that medical students get enough instruction in the principles of nursing, that they watch all major nursing measures carried out by experts, and that no young doctor enters general practice (as many do at present) grossly ignorant of one side of the care of the sick. We must not be afraid to learn from one another: it has long been the great pride of medicine and nursing that knowledge is freely shared.

THE BASIC SALARY

ON Monday the House of Commons, by 303 votes to 128, declined to say that remuneration of general practitioners in the National Health Service should normally be by capitation fees alone. Much was made of the advantages of a basic salary. But there would also be great advantages in reserving such a salary, as the House of Lords suggested, for circumstances in which it is clearly required. By accepting this arrangement the Government could have gone far to secure the willing participation of practitioners in the service. Happily the Minister's words, as reported on p. 697, allow us to hope that this question will be reconsidered in the coming negotiations.

Sir EDWARD THORNTON, late secretary for public health and chief medical officer for the Union of South Africa, has died at Pretoria. A former D.G.M.S. of the Union's Defence Forces, he later held the appointment of director-general of rehabilitation training. He was 68 years of age.

Reconstruction

MEDICAL ADVISORY COMMITTEES IN THE REGIONS

FROM A CORRESPONDENT

THE day is drawing near when the Minister of Health must appoint the regional boards. There has been a good deal of discussion about the area and functions of the boards, but comparatively little attention has been paid to their probable modus operandi. The object of this article is to point out that the regional organisation will in many important respects resemble that of a large hospital; and that in constituting the board the lessons of experience should play their proper part.

Detail, we are assured, will be delegated to the hospital management committees. Nevertheless, the board will eventually have to decide in broad principle questions which have agitated every hospital. For example, what share of the available funds shall be devoted to this or that form of medical advance? Shall effort be concentrated on tuberculosis, or on cancer, or on rheumatism? Shall the reconstruction of hospitals take precedence over the establishment of maternity units, or vice versa? There is no need to elaborate. In all such matters there is room for debate, and we cannot expect that progress will cease to be attended by a large diversity of opinion. Decisions of this order have in the past been the hard core of hospital management, and the regional boards will have to deal with them on a great scale.

What can experience teach us? The lesson is plain. It is that in the twin machinery of governing body and medical staff committee we have a pattern which it would be folly to ignore. The accepted practice in nearly all our great voluntary hospitals was well described in the recent debate in the House of Lords by Lord Moran:

> "In the voluntary hospitals there is a medical staff committee, composed, as a general rule, of all the staff. . . . It is the duty of each of those members (who are connected with every kind of special service) to keep their colleagues informed of any new equipment or any new development of knowledge, wherever it may occur, all over the world. It is a unique instrument for keeping the management of the hospital up to date in practical matters. When the members of the committee have been so informed and have decided whether their colleagues' proposal is or is not justified, then a number of them sit on the board of management . . . and try to convince the board that this or that should be done. . . . It is a measure designed to afford technical advice to the board of management so as to keep the hospital up to date in its administration."

People sometimes forget, however, that the efficiency of this well-tried machinery depends on the respective constitution of the two bodies, and may readily be destroyed if their functions are not kept distinct. Thus if too many doctors sit on the board, the effect is to transfer to that body discussions which ought properly to take place in the medical staff committee. The true function of the representatives of the medical staff committee on the board of the hospital is not to debate among themselves the pros and cons of different policies, but to convey to the governors the considered opinion of the medical staff as a whole. A wrong arrangement, sometimes made in deference to the desire to provide ample representation for the medical staff, defeats its own end: it confuses the lay body, and it mutilates the medical staff committee by removing from it the effective discussion of policy.

If then we are right in seeing a close analogy between the essential functions of the management of a great hospital and the work of the regional boards, it follows that very careful consideration ought to be given to their composition and to their relationship with the medical advisory committees which we hope to see set up alongside them.

The Bill lays down that a regional board shall include

- (*a*) persons appointed after consultation with the universities with which the provision of hospital and specialist services in the area of the board is to be associated
- (*b*) persons appointed after consultation with such organisations as the Minister may recognise as of the medical profession in the said area or the medical profession generally;
- (*c*) persons appointed after consultation with the local health authorities in the said area; and
- (*d*) persons appointed after consultation with such other organisations as appear to the Minister to be concerned

and the original members of the board shall also include persons appointed after consultation with such organisations as the Minister may recognise as representative of voluntary hospitals in the said area.

At least two of the members of the board shall be persons with experience in mental-health services.

Is there not a real risk that such a constitution may unwittingly, and with the best of motives, lead to the relegation of the medical advisory committee to entirely subordinate position? It may be said that the need is substantially met by the representation of the medical interests on the regional board *itself. But* a little reflection will show that this is a mistaken view. The medical advisory committee ought to enable the medical staff of the hospitals of the region to participate at first hand in the development of policy: it is the men who are actually working in the hospitals who know the real relative urgency of the need for this or that. Moreover, the medical advisory committee ought to reflect—as does the medical staff committee of an individual hospital—the whole range of medical work and all the various specialties: otherwise it is unlikely to achieve a balanced outlook on the needs of the hospitals. These needs will not be met by a team of men on the regional board selected in accordance with the schedule quoted above. The university men will be drawn from the teaching hospitals; the nominees of the profession will naturally and rightly include general practitioners; the local authorities will put forward their medical officers of health; and there will be very little, if any, room for the men engaged in active work in the non-teaching hospitals of the region.

It is not, therefore, a mere flight of fancy to press that a medical advisory committee for the region is a necessity and not a luxury. The regional machinery must embody the twin organisation that has served the hospitals so well in the past.

TWO OBJECTIVES

To achieve this the Minister must so manage matters that two objectives are kept in view. On the one hand, the claims of medical interests to representation on the policy-making body must not be allowed to obscure its essentially financial and administrative character. On the other hand, the link between the medical advisory committee and the medical representation on the board must be such that the committee feels itself able to make its voice clearly heard in the board's deliberations. Its own elected chairman, and perhaps its medical secretary too, ought to be among the most influential members of the board. If the boards must be constituted before the medical advisory committees, seats on the boards ought to be reserved for representatives of the committees.

These objectives may not be easy to achieve, but unless they are kept very much to the fore the hospitals in the regions may find themselves governed by bodies that lack the machinery for effective liaison with those who possess first-hand experience of the need. A lively and useful medical advisory committee in each region will remain a dream unless the arrangements now made are such as to enable it to play a real and not only a paper part in the determination of policy.

Special Articles

HILDLESSNESS AND THE SMALL FAMILY

A FERTILITY SURVEY IN LUTON

RICHARD M. TITMUSS   FRED GRUNDY
M.D. Leeds, D.P.H.

IT is well known that there are many gaps in ur knowledge of current reproductive patterns. The deficiencies fall broadly into two classes: (1) facts concerning marriage, birth, and the size of families, and 2) the causes determining these facts. This paper is chiefly confined to a study of some fresh material, and s mainly factual in content.

The last, and only, census in Great Britain which asked women who were married or had been married how many children they had borne was taken in 1911. Since then, the birth-rate has fallen by about 40%. Motives and values have been transformed. "All the known facts, supposed facts, acknowledged goals, dreamed goals, experiences and expectations about economic pressure, material inconveniences, and social ambitions"[1] which enter into the decisions of one generation of parents may be weighted by a different set of secret coefficients by the next generation. We need, therefore, in order to understand the problems of the contemporary family, something more up to date than the census of 1911.

The Population (Statistics) Act of 1938 required certain essential information, like the age of the mother and the number of previous children, to be supplied on registration of every birth. But this only tells us each year about the 5% or so of women of childbearing age who give birth to a child. We learn nothing about the women who have recently passed out of the reproductive period or of the younger women who remain childless. We can still only guess, therefore, about the incidence of childless wives. The Royal Commission on Population has recently been engaged in gathering much new material and analysing a mass of statistical data that have flowed into its hands and into the records of the General Register Office. So far, however, the commission has not reported, and the data that have been made available to it have not yet been published.

When, in the summer and autumn of 1945, a social survey was launched in the borough of Luton (population approximately 101,000) the opportunity was taken to obtain at the same time information about some of these matters. For a full description of the survey, its method and operation, reference should be made to *Report on Luton*,[2] which includes an account of the problems of the questionnaire, sampling, coding, and analysis, together with a set of population tables.

So far as the fertility analysis is concerned, informaion was obtained from samples totalling 3803 married women. The cards relating to these women have been dissected according to age, duration of marriage, social class, interval between pregnancies, birth wastage, and size of family. Some of this material has been drawn upon, and condensed, in the following tables. It is hoped to publish a full report later.

CHILDLESSNESS

Table I sets out the proportions of childless wives in Luton. Women married more than once, divorced, separated, widowed, or deserted by their husbands are excluded from this and subsequent tables; and any absence of husbands on war service has been disregarded.

Section i of this table is not, of course, comparable with sections ii–iv, because some, or many, of the women it examines may still bear children. We may, however, reasonably compare marriage durations of over 20 years, for not many women who have been married for that length of time and are still barren will have children.

Although it is commonly stated that there has been an increase in childlessness, this table does not confirm that supposition. Among those married under the age of 25 and for 20 years or more, for instance, the women who may still have babies show a smaller incidence of childlessness—less than 10%—than those who have passed their reproductive period. A division of the over-45 group into two subgroups covering all marriage durations—those aged 45–60 and 60 plus—shows a proportion of 19% for the former and 30% for the older generation. Among these two subgroups mortality has, of course, been operating to remove with advancing age a higher proportion of women from the sampled population. This process has probably been selective, but not so as to remove a smaller proportion of childless wives. Although the evidence is not conclusive, the studies that have been made of British material suggest that rates of mortality are lower among mothers than among childless married women. Some of the physiological factors which prevent childbirth also lead to earlier death.

The effects of mortality are therefore unlikely to explain the difference in the proportions childless in the two groups. The figure of 30% for those aged over 60 is unexpectedly high. One possible explanation, drawn from the history of the hat trade in Luton, is that the employment of large numbers of local women 30–50 years ago may have led to a higher incidence of childlessness, partly because of selective migration into the town, partly because of the economic inducements to remain childless, and partly because of the effect of bad conditions of work on the health of the women. If this is so, it means that the data for these older women are, from a national point of view, unrepresentative. Nevertheless, even if this percentage of 30 is discounted somewhat, there is still little in table I to suggest a rise in childlessness.

It may well be that the general belief in an increase of sterility and childlessness in recent decades is due to a

TABLE I—PERCENTAGE OF MARRIED WOMEN WHO HAVE NOT BORNE AT LEAST ONE LIVE CHILD*

2. Grundy, F., Titmuss, R. M., and others. 1945. Luton: Gibbs, Bamforth & Co. (Luton) Ltd.

growing recognition of its importance in relation to the population question, rather than to any real enlargement of the problem. It is not impossible, too, that an over-diagnosis of sterility reflects a medical fashion of recent origin. But, whatever the explanation, the belief is not founded on ascertained fact, and the Luton material does not point to an increase of sterility.

The conclusion that there is no evidence of increasing childlessness could be invalidated if it were true that a larger proportion of women were not entering marriage, and further that those not doing so contained the group who would not, for physiological or psychological reasons, have had children if they had married. But, as the marriage-rate is very high in Luton, it is most unlikely that this factor of selective marriage is more important today than it was in the past. Much the same may be said for the country as a whole.

The proportion of Luton women aged 15–20 who were married was as high as 7·2% in 1945 (against 2·3% for England and Wales in 1939[3]), while at ages 25–35 83% were married (against 71% for England and Wales in 1939). By age 45 only 8% of Luton women remained unmarried. It would be almost impossible to raise the proportion above this level in Luton—or in the country as a whole. Such figures as these, expressing the high popularity of the social institution of marriage, provide, indeed, a greater reservoir of potentially childless marriages, and (it may be added) for divorces and separations.[4]

CHILDLESSNESS IN DIFFERENT SOCIAL GROUPS

The data comprising table I have been analysed according to the occupation of the husband, and the classification into social classes has followed that adopted by the Registrar-General at the last census. The number of women falling into social classes I and II is too small for the results to be significant, partly because Luton is pre-eminently a town of artisans, 62% of its men aged 20–65 being skilled workers, many of whom enjoy an income higher than most of the clerical and professional groups allotted by the Registrar-General to class II. The Luton material has, therefore, been analysed for two groups, (*a*) skilled workers (social class III), and (*b*) semi-skilled and unskilled workers (social classes IV and V).

Among women aged under 45 in 1945 the proportions childless are:

—		(*a*) %	(*b*) %	All social classes, including I and II (%)
Duration of marriage	15–20 years ..	11	11	11
	20 years and over	6	7	6

For those aged over 45 in 1945 with a marriage duration of 20 years and over:

—	(*a*) %	(*b*) %	All social classes, including I and II (%)
Age at marriage 15–20 yr. ..	11	10	9
„ „ 20–25 yr. ..	14	12	14
„ „ 25–30 yr. ..	24	19	22

Here again there is nothing to suggest a rise in the proportion of childless wives. Nor is there anything to warrant the prevailing idea that childlessness is commoner among those in classes I and II. There may be more childless wives because the age at marriage is higher in the higher income groups, but given the sa age at marriage then there does not appear to be m difference in the incidence of childlessness among soc classes—at least in Luton.

CONTROLLED PARENTHOOD

While the Luton fertility tables do not show that greater number of women are remaining childless, wh they do reveal is the extent to which controlled paren hood is today being exercised by all age-groups and soc classes. In table I, for instance, it is shown that afte an average of 2½ years of marriage only about half of the wives had had a child, and that after 7½ years a third of all the women married at 25–35 were still childless

TABLE II—PERCENTAGE OF WIVES AGED UNDER 45 IN 194 HAVING AT LEAST ONE OR TWO CHILDREN WITHIN THE FIR FIVE YEARS OF MARRIAGE

Duration of marriage at mid-1945 (yr.)	Women married between age—							
	15–20		20–25		25–30		30–35	
	Children		Children		Children		Children	
	1	2	1	2	1	2	1	2
5–10 ..	81	42	65	17	55	11	57	11
10–15 ..	87	41	73	25	59	10	54	9
15–20 ..	87	42	77	23	70	22	—	—
20 plus ..	77	38	82	29	—	—	—	—

TABLE III—DISTRIBUTION OF LIVE-BORN CHILDREN TO WIVES AGED UNDER 45 IN 1945 AFTER A MARRIAGE DURATION OF 10–15 YEARS

Women married between age—	Percentage of wives with the following family sizes—						Mean number of children per married woman
	0	1	2	3	4	5 plus	
20–25	8	34	33	16	5	4	1 90
25–30	19	41	26	10	1	3	1·41

It has long been recognised that earlier marriages are more fruitful of children than late ones. This has been true even when marriages contracted between ages 15–20 and 25–30 are compared. Thus the 1911 census showed that after 2½ years of marriage the number of children born to 100 wives married at 15–20 was 60% higher than the number born to those married at 25–30 The corresponding figure for Luton women in 1945 was 23%.[5] A change of this order strongly suggests that the degree of parenthood control, hitherto exercised by women marrying in the late twenties and early thirties, is now in process of being adopted by those marrying at earlier ages. The trend is towards a uniform pattern of reproductive behaviour within marriage. As there is a close correlation between social class and age at marriage—generally speaking high social status means high marriage age—then it seems likely that this development of uniformity applies to class fertility as well as to age-group fertility. Thus we should expect to find, when national data become available to compare with the 1911 material, a much smaller class fertility differential

Tables II and III present other aspects of current reproductive habits.

In reading these two tables it should be borne in mind that over half of all wives are married between the ages of 20–25. Next in importance to these ages is the group 25–30. Together, these two groups account for nearly 80% of all wives. It is the contribution made by these women which mainly determines the level of the reproduction-rate.

In table II, and examining first the most recent marriages, we see that after 5–10 years about twohirds of those married between 20–30 had had one hild, while only about 15% had had two children. Women of these ages who have had only one child in he first 5–10 years of marriage are unlikely to end heir reproductive days with a family of four or more. Yet the 1911 census found that among the great group of wives married at 20–25 and whose marriages were contracted in 1851–61, the commonest size of family was ten. In 1945 the potential for large families in a similar age-group, who were married between 1935–40, was only 17%. But while this 17% may go on to three or more children, the next group of women who married during 1940–45 between ages 20–25 may provide an even smaller potential. For, as can be seen from table II, the proportion has fallen sharply from 29% (those married before 1925) to 17% (those married between 1935–40).

---

[3] Later figures have not been published.

[4] It is a common mistake, particularly evident in the popular press, to assume a greater incidence of broken homes because the number of separations increases. But this is not necessarily so; and they should be measured against the numbers exposed to the risk of separation.

[5] This percentage may be abnormally low because of war-time marriages among young people, and the incentives for women to have at least one child. But such factors cannot explain away the difference between 23% and 60%.

This particular story is taken a little further in table III. The marriage duration of 10–15 years has been selected because it may reasonably be assumed that, after this period of married life, the *ultimate* size of the family has been more or less set by the vast majority of couples.[6]

What is most striking about this table is that for both those married at 20–25 and at 25–30 the *commonest* family size was one. At the time of the survey the age of these women ranged between 30 and 45, with a mean of approximately 37. When the childbearing days of these women are over no doubt the 19% of childless wives married at 25–30 will have been reduced, while some of the one's will have moved up to the two's. But is it likely that many of the 75% (married at 20–25) and 86% (married at 25–30) who had less than three children after a mean of 12½ years of married life will finish with three, four, or five children?

PREGNANCY SPACING

To supplement the Luton fertility survey, which covered the childless and childbearing women of all ages, an analysis was made of the pregnancy histories of all married women who bore a live child during 1945.[7] A total of 1961 women entered the tables, and they were grouped as to:

		%
714	first pregnancies	36
630	second "	32
325	third "	17
140	fourth "	7
152	fifth plus "	8=100%

A study of the interval between marriage and the first pregnancy showed that, among women aged 15–20 in 1945, all the pregnancies (52) occurred in the first three years of marriage. In the group aged 20–25, more than three years elapsed before 26% recorded a pregnancy; at ages 25–30 the proportion was 62%, and at 30–35 as high as 81%. At all ages combined, 53% of the wives giving birth to a live child in 1945 had a pregnancy during the first three years of marriage, and a further 18% did so in the next two years. In other words, nearly a third of these fertile women had been married more than five years before having a pregnancy.

As regards second pregnancies, only 29% of all the wives reported one during the first five years. For 50%, between 5 and 10 years elapsed before a second pregnancy occurred, and for 21% more than ten years.

Very few third pregnancies were recorded in the first five years (only 11%), 48% between 5 and 10 years, and 41% thereafter. When fourth and subsequent pregnancies are analysed, it is seen that less than 2% of all wives might be said to be continuously childbearing, for this was roughly the proportion who had had four pregnancies in the first five years of marriage. Of such pregnancies 60% occurred after ten years (20% after fifteen years), and 80% of fifth plus pregnancies after ten years (40% after fifteen years).

TABLE IV—SIZE OF FAMILIES. RELATIVE FREQUENCY OF FAMILIES OF DIFFERENT SIZES BORN TO WIVES MARRIED AT AGE 20–25

Children born	Luton: Wives aged under 45 in 1945 whose marriages had lasted 15–20 years	Luton: Wives aged 45–60 in 1945	Luton: Wives aged 60 plus in 1945	England and Wales (1911 census): Wives aged 50–65 in 1911
0 ..	10	11	22	6
1 ..	33	26	22	4
2 ..	28	26	13	6
3 ..	13	13	13	8
4 ..	9	9	7	9
5 plus	7	15	23	67
—	100	100	100	100

To summarise these results for all married women having a live-born child in 1945:

Women reporting a second pregnancy—
for 71% over five years of marriage had elapsed.
Women reporting a third pregnancy—
for 41% over ten years of marriage had elapsed.
Women reporting a fourth pregnancy—
for 60% over ten years of marriage had elapsed.
Women reporting a fifth or subsequent pregnancy—
for 40% over fifteen years of marriage had elapsed.

These figures express in concrete form the extent to which controlled parenthood has now become a part of the married lives of all sections of the community. Their effect on family size may be gauged by comparing the data for women who had not reached the age of 45 in 1945, but whose marriages had lasted between 15 and 20 years, with corresponding data for women whose reproductive days were over (table IV).

The large family of five or more children is, it seems, fast disappearing. The full psychological, social, and economic consequences of the changes in family size depicted in table IV have not yet been experienced. While great numbers of middle-aged and elderly people alive today have, or have had, a large supporting circle of brothers, sisters, and relatives, this will not be true of the children born of contemporary fertility patterns. We do not yet know what kind of problems will arise, and what type of society will be fashioned, by the generations composed of large numbers of one-child and two-child families when they reach maturity and responsibility. All the signs point to a—physically—healthier society. But in other respects there may be losses, for in the absence of biological supports and the safety-valve of religious exercise, the central issue of the future may well be, in Fromm's words, the problem of "moral aloneness."[8]

CONCLUSIONS AND SUMMARY

A study has been made of a few aspects of the problem of parenthood as revealed by a sample fertility survey in the industrial town of Luton. It would, of course, be wrong to assume that what is true of Luton is also true of the rest of the country. Other towns, such as Liverpool or Glasgow, with dissimilar social structures might show different patterns. Moreover, it should not be forgotten that many of the facts presented here reflect the abnormal war-time phenomena of high and youthful marriage-rates, and a consequent piling up of first births. These factors tend to distort comparisons with pre-war years. Nevertheless, it may reasonably be claimed that the facts reported roughly indicate the

---

[6] If 1 or 2 children have been born within this period, then the size of the family when childbearing is completed may be 2 or 3, but it is unlikely to be 4 or 5.

[7] By present husband. These histories were obtained in respect of women delivered by midwives, in the borough's maternity home, in private practice (including private nursing-homes), and in the public assistance institution. It was interesting to note how atypical were the cases handled by private practice, for while as many as 54% of the women were aged over 30 84% of the pregnancies were first and second.

[8] Fromm, E. Fear of Freedom, London, 1945.

order of magnitude of the problems studied as they obtain today in the mass of industrialised communities in England.

Throughout the war of 1939–45 Luton's birth-rate—e.g., total live births related to total resident population of all ages—was higher than that in the country as a whole. Yet in 1945, when Luton's rate stood at 18·9 per 1000 population (as compared with 16·1 for England and Wales), the number of live births to 1000 married women aged 15–49 was only 88 in contrast to a figure of 92 for England and Wales in 1938. On the other hand the net reproduction-rate in Luton was above unity—namely, 1·03 for 1944–45—while this index stood at 0·95 for England and Wales. As Luton's birth-rate in 1938 was higher than the national rate in the same year, it seems, from a comparison with the figures for 1944–45, that the relatively large number of births in the town during the war years has not meant any increase in fertility *within marriage*. There were many more marriages, especially youthful ones, and a rise in the proportion of first-born children. It is highly probable that a corresponding development took place in the rest of the country, but until comprehensive national data have been published we cannot be sure.

The more notable biological facts reported in this paper may be summarised as follows:

(1) There is no evidence of any increase in the proportion of childless marriages over three generations, and (given the same age at marriage) no marked social class differences.
(2) The degree of control over childbearing within marriage, hitherto exercised by women marrying in the late twenties and early thirties, is now in process of being adopted by those marrying at earlier ages.
(3) For many wives there is now a long interval of time between marriage and the first pregnancy, and between first and subsequent pregnancies.
(4) Only a small proportion—less than 2%—of all wives can now be described as continuously childbearing.
(5) A large increase has been noted in the proportion of one-child and two-child families in recent years, and a dramatic fall in the proportion of families containing five or more children.
(6) The trend towards a smaller family size continued during the war—despite a rise in the birth- and reproduction-rates.

OUR MENTAL HOSPITALS

REPORT OF THE BOARD OF CONTROL FOR 1945

DURING the war the Board of Control ceased to publish their annual reports; so the report for the year 1945, the first to appear since 1939, has much to tell—and, surprisingly, much that is cheering.

Mental hospitals and mental-deficiency institutions evacuated 25,000 beds at the outbreak of war, thus putting space for some 42,000 beds at the disposal of the Forces and the Emergency Medical Service. In the hospitals to which the displaced mental patients were removed this meant overcrowding amounting at one time to 16%; and those who were then working in mental hospitals well remember the gloomy prognoses the sight of the close-packed beds invited. Yet few of the fears were fulfilled: certainly the death-rate increased during the early years, reaching in 1941 a point 33% higher than the pre-war average; but thereafter it slowly fell, until in 1945 it was just below the rate for 1935–39—68·4 per 1000 patients compared with 68·5. The death-rate for women in 1943 was 64 per 1000, among the lowest ever recorded; and it is curious to note that this happened when the shortage of nurses was greater than at any time during the century. This record may be compared with that of the previous war, when by 1918 the death-rate had risen to a maximum of 203 per 1000, or 111% over the pre-war quinquennial rate.

Nor was the increase of tuberculosis as devastati as had been expected. The incidence of fresh cas rose from 5·6 per 1000 in 1939 to 11·3 in 1941, but th began to fall, reaching 7·2 in 1945. The death-rate fro tuberculosis, which was 3·8 in 1938 and 4·1 in 1939, ro to 9 per 1000 in 1942, but had fallen to 5 in 19 Similarly the death-rate from dysentery showed temporary rise, reaching a peak in 1941, then quickl returning to the 1938 level; by 1945 it was only 0 per 1000 patients.

THE RULING FACTOR

What was the cause of this gradual change for th better, starting in mid-war? Evidently it cannot be put down to any improvement in living conditions, for the were throughout worse than in the 1914–18 war, when the death-rate in mental hospitals steadily rose. Overcrowding was greater in the recent war, blackout more strict, ventilation poorer, staff shortage more acute, enemy action more violent. Certainly the diagnosis of tuberculosis was made earlier, thanks to the intensive use of X rays; and the treatment of dysentery is nowadays more successful; but these measures alone could not have changed a main trend.

After the 1914–18 war the board concluded that reduction in quantity and deterioration in quality of food supplied to the patients was the chief factor inducing the increased sickness- and death-rates in mental hospitals. This time the board were on their guard. Mental patients customarily lose weight in the first two years of their illness, but in 1941 the board initiated studies to decide whether the losses were greater than in the pr war years, and also whether overcrowding was havin an effect on weight-loss. The degree of overcrowdin existing at that time was found to make no differenc to the proportion of patients losing weight; and fro 1941 onwards the situation righted itself, weight-los reverting to the pre-war range.

> "The recovery was due, we believe," the board wri "to the changes induced in the latter half of 1941 as a res of which the food situation improved, and also becau we became food-conscious and much was done to impro the quantity and balance of the diet."

Dietaries were investigated not in the rosy light the official diet sheet but by studies of the bulk issu of food over a period of four weeks. The mean val was found to be 2360 calories daily, ranging from 19 to 2731, whereas, since 1941, the level in the gener population has been 2800 calories. In about half th hospitals the amounts of vitamins included in the foo was below the League of Nations level. The analys enabled a large number of hospitals to change the diets and particularly to improve the supply of vitamin C and A; on the whole the board feel that from 194 onwards the diet was satisfactory, and they attribute th better health and welfare of the patients largely to thi change.

In the early days, however, nobody could foresee th comparatively happy outcome, and many mental-ho pital doctors and nurses felt indignant at what seeme a cynical disregard of their patients' welfare. It is wort noting in passing that their discontent could have bee changed to willing support if a member of the board, a Government official, however minor, had visited th hospitals and explained to the assembled staff in te minutes what the relinquished space meant to the natio at large. It is imaginative dealing with the peop on the spot which makes the difference between a happ and a disgruntled service—a point worth bearing in min when the National Health Service is established.

WAR AND MENTAL HEALTH

The effect of the war on the mental health of th community has been impossible to estimate. Th train imposed by air attacks and family anxieties was artly offset by opportunities for full employment, a etter standard of living, and the stimulus to the spirit f team-work in an important cause. Admissions to nental hospitals in 1940, 1941, and 1942 were lower, he board report, than the average for the five years before the war. By 1943 they had exceeded this average, and continued to rise in the next two years, reaching 33.961 in 1945, the highest number on record. But no fewer than 50·7% of these admissions were voluntary, and the patients discharged that year amounted to 71·7% of the direct admissions—also the highest figure on record. The percentage of patients, calculated on direct admissions during the year, who left mental hospitals recovered or relieved was 63; and for recoveries alone the figure was 33·2. The percentage of absolute discharges (including those who were not improved and 150 who absconded) was 71·7, compared with 66·8 for the preceding five years. The average annual percentage for the five years before the operation of the Mental Treatment Act, 1930, was 48·3.

DEMAND AND SUPPLY

The hospitals, in fact, are being used earlier and willingly by people with incipient mental illness, and a continued rise in admissions is therefore possible. To meet it we have old buildings, too few beds, and a staff shortage. At the end of 1945, bed-space for 17,020 mental patients still remained in the hands of the Services and the E.M.S., and a further 847 beds were not in use because they could not be staffed. For mental defectives, especially, it is often difficult to find institutional vacancies even when their need is urgent. The board draw fresh attention to the report of the Athlone Committee's subcommittee on the mental-nursing service, in which better conditions of service for the mental nurses were advocated.

SERVICES AFTERCARE SCHEME

In 1943, at the request of the War Office, the board founded a scheme for aftercare of ex-Service patients discharged from hospitals and E.M.S. centres on account of psychiatric disability, and in 1944 merchant seamen were included. The Ministries of Pensions, Labour, and Health, the Provisional National Council for Mental Health, and the Mental After Care Association all gave their help in this specialised form of reablement, and up to September, 1945, some 7800 patients had been referred to the board for help. The Provisional National Council arranged for patients to be visited in hospital by a trained social worker; and regional aftercare officers look after them in the areas to which they are discharged. No patient is referred unless in the opinion of the commanding officer he or she needs aftercare and has expressed willingness to receive it. As new cases are referred those whose needs have been met are closed down, but in 1945 new cases were still outrunning the numbers requiring no further help. The board note that the scheme could be extended and help given to other members of the Forces were it not for the shortage of trained psychiatric social workers.

They have been closely concerned with plans for integrating the mental-health service with the National Health Service. One aspect of this calls for the rewriting of the Lunacy Code, a task which would already have been undertaken but for the war. In 1926 the Royal Commission advised that the code should be recast and simplified, and the need is now urgent since the National Health Service Act will modify the Mental Treatment and Mental Deficiency Acts.

The report as a whole gives a picture of a promising and improving service badly hampered by lack of nursing staff and proper buildings. The staffing of mental hospitals is a part of the whole nursing problem, which is still not being faced realistically.

In England Now

A Running Commentary by Peripatetic Correspondents

I THOUGHT that I had attained to that sublime pose for which the tag of Horace serves as slogan—nil admirari—but my self-esteem has received a rude shock, for I am full of wonder. I have just returned from a brief visit to our hospitals in the Middle East, where I found the hygienic conditions contrasted so favourably with those of the last war that it seemed as if a miracle had been performed.

Thirty years ago I landed with a large medical unit at Basra, and within a fortnight half the officers were sick and in hospital. At that time flies and mosquitoes swarmed round the camps, dysentery was rife and malaria dangerously common, while the river steamers were crowded with sick on their way to India. Heavy chlorination gave the drinking-water a strong antiseptic flavour. For more than two years my daily ration for a bath was a petrol tin filled with water, which was carefully poured into the shallow canvas bath which each officer carried in his kit. The thought of an immersion-bath was a dream of Paradise. Latrines were primitive and the incinerator a prominent feature of the landscape. A commission which was sent out from England to inquire into hygienic conditions soon demonstrated the need for improvement since three out of the four members soon fell sick and it fell to my lot to treat them.

But their work and that of their successors has borne fruit. Today, hygienic conditions are immeasurably better. Malaria control has worked wonders. During a three weeks' visit I saw fewer mosquitoes than I do in a London garden in one day. The regular use of D.D.T. has almost banished flies; the water is pure and tasteless. The sickness-rate among the troops is but a quarter that of the last war. In the various hospital camps one can always have the luxury of a cold shower-bath, and sometimes even hot water is laid on. It only added to the interest to find that in one camp a toad appreciated the same amenities as the members of the mess. We thought the acme of luxury was the flushing water-closet far away in the desert.

The only sad and deeply felt regret came when one saw the huge cemeteries filled with those who would almost certainly have been saved if similar conditions and precautions had existed thirty years ago.

* * *

My wife says it's her turn: so over to her.

At 3.45 A.M. the phone rings. "Poor old boy, you'll have to get up," I mutter thickly into the darkness. An awful blast of cold air and even colder invective makes me curl up and pull my nightdress around my toes. He gets up, his super renal whatnots working at high pressure. From a long distance I hear that there has been an accident, so I roll over to keep his side of the bed warm.

How I envy those efficient wives who, when their husbands are called out, turn over and go to sleep in an instant! My imagination is too much for me (I often wish he would share some of it with me, but he is usually too busy), or perhaps my renals are super super ones; anyway, I call out fit to wake the children, "Don't forget you took the bag out of the car, darling." He hisses back in the manner of Gielgud, "Sweetheart, I have remembered." Why do they get so angry with us, as we try to help? Poor chap, it's not my fault you get called out. It's something to do with his glands that he gets het up. He says he's a Kretchmer's picnic . . . the real trouble is that they all like to appear so efficient; any suggestion, any hint from us. . . .

The bed is warm now; how nasty to be lying on a roadside cut by glass . . . cold . . . shivering . . . surgical shock supervened. . . . "At the inquest Dr. Prem said that death was due to shock consequent upon the injuries." How nice he looks in his dark suit; the Coroner smiles faintly, "Thank you, doctor." Dr. Prem left the witness stand, his monumental calm, the air of faint resignation . . . so certain . . . so impregnable. I roll over in bed. "Phooey" I say aloud into the darkness.

I hear a train come into the station and the sound of boxes being dumped on the platform. Fish. I must queue up early again. In a few minutes the milk train will be in. I remember listening to them like this the night Pauline had her second. Fish and milk, babies and chores, and queues. They are packed like sardines waiting to see the doctor, I have to wait patiently in a long reptilian queue to get sardines: there is nothing funny in this any more.

I doze and then wake with a start to the sound of a siren. It is the whistling kettle. He is going to bring me tea and we are going to sit in the half light of dawn and he's going to tell me what happened. He brings me the tea and gets my bedwrap. He lights a cigarette, the smoke comes out through his nose and he begins, "They moved them off the road and took them into a luxurious nature cure place. . . ." We laugh happily. Just between you and me—it's going to be a wonderful day today.

* * *

Within a twelvemonth I have climbed in England, Scotland, Ireland, and Wales. More: I have achieved my Lakeland majority, for a few days ago I returned from my twenty-first visit to the Cumberland Fells.

"I know those slopes: who knows them if not I?" sang Matthew Arnold, and I feel qualified now to claim the same familiarity with the route from Sty Head to Sca Fell as with the exposure of the saphenous opening after many (too many) years in the Royal Air Force.

And how much nicer, I have been reflecting, are the Cumbrian names than those of the other mountainous parts! Stickle Tarn and Scale Force; the simplicity of Gable and Pillar—contrast these with Lliwedd or Clogwyn Du'r-arddu, which may mean something to a Welshman, or with Stuc-a Choire Dhuibh Bhig, which a Highlander has the satisfaction of knowing means the peak of the little black bastards, or something to that effect. True, Crib Goch (Wales) and Suilven (Scotland) have stern uncompromising names suited to their appearance, but they lack the music of Watendlath or the fantasy of Dollywaggon Pike. Ireland fares a little better. Errigal and Muckish, Hungry Mountain, and the Poisoned Glen immediately suggest visions of the Little People, but Sgùrr a' Mhadaidh or y Ddysgl suggest nothing at all to a Sassenach, unless it be a comparison with such horrors of medical terminology as axonotmesis or dysdiadokokinesis, which, even if you know what they mean (and it is usually something pretty simple) are completely unpronounceable.

Incidentally, names aren't the only things which are more attractive in the Fells than in the Highlands or Snowdonia. Why, even the sheep look more intelligent, and as for the natives themselves—but those are deeper waters. Anyway, what Scot or Celt could possibly have thought of calling a mountain track anything so delightful as Moses Trod?

* * *

The Ministry of Food's appeal to doctors to go easy in issuing certificates for priority milk cuts at the very tap-root of medical practice—the doctor-patient relationship. The doctor's first loyalty, we keep saying, is to his patient: and here we are being asked to consider the interests of the community, as represented by the "normal consumer."

The doctor knows all about the troubles of normal consumers—he is usually one himself—but that doesn't make it any easier to refuse the plea of old Mrs. Muggins up the road, even though one suspects that most of the 14 pints a week that she gets for her duodenal ulcer goes into the plates of her three sons' wheat flakes.

As a fellow peripatetic remarked the other week, we doctors never asked to be the controllers of the nation's milk-supply, and we would be heartily glad to be rid of the whole time-consuming and thankless job. But nobody else is capable of taking it on, so we must make the best of it. What we are asked to do is to make a 44% cut in present certificates, and at least that would be saved for normal consumers if we could limit our certificates to people in the specified categories who are really going to drink the milk. The post-ulcer class is the one to keep an eye on, and I bet my boots that if they are cut down to the amount they actually drink we shall reach the 44% target with ease. We may have to instal a few chuckers-out in our surgeries, though. Will the Ministry of Food compensate us for loss of patients and for personal violence incurred in the exercise of our duty?

Letters to the Editor

CORONARY DISEASE

SIR,—In his Harveian Oration, based on his own larg experience, Sir Maurice Cassidy returns to the vexed question of ætiology which has so long employed th minds of all physicians having an interest in angin pectoris.

It is now apparent that we shall make small progre with our ætiological inquiries while we continue to confin our researches to individual studies in the ward, th consulting-room, the home, and the dead-house. This is a disease of prevalence, a community disease, with particular age and sex associations and a rising national incidence which must surely be related to social changes and to occupational or habitual factors. What, in fact, are the most striking changes in the conduct and conditions of our lives accompanying the steady increase in the disease? The amount of mental work and of mental and emotional stimulation now possible in the course of a single day is something far in excess of anything experienced by our ancestors. The time has come to accept that the pace and pressure of life and their physiological consequences for neuromuscular systems are no longer things to be ignored, as *malnutrition in relation to other sickness and mortality* was ignored until a few decades ago.

Reference to the Registrar-General's Decennial Supplement (1930–32) and to the social post-mortem examinations which this volume so usefully and graphically illustrates reveals important evidence. The standardised mortality ratios for angina pectoris, grouped according to social class by occupation, indicate that the male death-rate for social class I (professional classes) is nearly 3½ times that for classes IV and V (working classes), the intermediate classes II and III showing an intermediate gradient. The tables disclose further that, whereas in class I the standardised ratio for males is much in excess of that for married women and equal in class III, it is in defect in classes IV and V.

All this evidence would seem to suggest that—setting aside the partial contributions of age, sex, and heredity—conditions of life and work must play an essential part, and further that particular forms of social and occupational experience are as surely responsible factors as are those forms of social experience which weight the scales in favour of the professional classes and against the working classes in the case of tuberculosis, rheumatic heart disease, gastric (but not duodenal) ulcer, and cancer of the skin and stomach. In an analysis of a serie of private cases of coronary thrombosis a few years ag I found (after excluding, in order to discount the agein factor, all cases at and over 60) that I had noted th coincidence of heavy mental or emotional strain in 40% of the remaining male cases. I had been making n ad-hoc study of ætiological factors during the years i which the records were accumulated.

When we come to a closer consideration of occupationa influence we find (again from the Registrar-General' tables) that medical men and the members of othe intellectual professions in a less degree have a muc worse experience in respect of angina pectoris than an of the manual occupations. Taking 100 to represen the death-rate for all males between ages 20–65, th comparative figure for agricultural and gardener labourers is 32; for coal-miners below ground 40; fo bank and insurance officials 183; for the Anglican clerg 218; and for physicians and surgeons 308. Whe modern "psychosomatic" theory has tended to stres the importance of emotional conflict and repressio (which largely reflect temperament) social statistics an clinical histories make a stronger case for such facto as mental overactivity or strain and the day-to-da cares of sustained responsibility, which largely refle types of employment.

More intimate sociomedical investigations of all th prevailing chronic diseases of our age are now neede The "multiple stress" diseases and accidental injuri in the western world are as worthy of epidemiologic inquiry as the diseases due to infective agents. The now cause more loss of life and efficiency and call fo a greater expenditure of time and money than th ommunicable diseases. Like these they are due to a omplexity of causes which vary with time and place nd social change and which can, by appropriate methods, e unravelled. Unlike them they lack a specific factor which can sometimes be specifically countered. But social onditions and modes of work and habits are—albeit lowly—alterable things.

Oxford. JOHN A. RYLE.

NURSING

SIR,—The "experimental school of nursing" advocated n your leading article of Oct. 26 would be a useful piece f work, and certainly the time has come for some ractical research into nursing techniques and the art f nursing as distinct from medical care.

I should not like to see the research progressing along he lines of exploration of the possibilities of a two-year asic course. The assistant-nurse training is the simple ourse in elementary nursing arts, and would in my pinion not be suitable for the girl of good education, who is interested in theory as well as practice, and can bsorb both at a greater speed and to a greater degree han the type of candidate for whom the assistant-nurse ourse has been devised. The assistant nurse can always ass on to full training if she proves suitable.

I do not quite see the reason for the proposal of a 'medical dean" for a nursing school. I would prefer a chool committee with a nurse as chairman, and represen-ation from the medical committee.

I fully agree that any nursing course based largely on the medical curriculum is likely to be unsatisfactory, but there must always be correlation between medical and nursing teaching. Ward and departmental sisters should have a definite share in the teaching of the curriculum, and an investigation into the number of patients for whom they can adequately care in addition to their teaching duties might well be made.

University College Hospital,
London, W.C.1.

MARJORIE HOUGHTON
Sister-tutor.

INFECTED FOOD

SIR,—Organisms of the food-poisoning group may be excreted by patients, after the cessation of clinical symptoms and signs, for a longer period than is generally realised. Only three cases of *Bacterium typhimurium* enteritis were encountered in my laboratory during the last year, but two gave positive stools after many weeks.

A married woman, aged 35, was ill for only a few days but was still excreting salmonella organisms in fair numbers 12 weeks after the initial infection. After the first weeks she was in good physical condition and continued her normal activities. Unfortunately contact was lost after the twelfth week, so it was impossible to learn the full time the carrier state persisted.

A married woman, aged 70, was ill for a longer period but was still excreting *Bact. typhimurium* 16 weeks after the onset. During this time, in an attempt to stop the carrier state, cholecystectomy was performed, but the gall-bladder, although containing stones, was sterile and excretion of the pathogen continued, although in scantier numbers. At the end of 16 weeks the fæces were still positive but the patient was in good health and engaged in her usual activities. Contact was unfortunately lost at this point and the complete time the excretion of the salmonella continued could not be recorded.

If these women had worked in a large feeding-centre an outbreak of enteritis would have been inevitable sooner or later.

The routine investigation of all "food-handlers in feeding-centres" would be of great value, but of still greater value would be the fæcal examination of all kitchen staff who develop any kind of "digestive upset," whether this caused absence from work or not. Conditions of temporary or permanent dysentery or salmonella carrier states would thus be detected.

It would be good too if doctors would become more preventive-medicine minded. On a number of occasions on inquiry into fæces results in cases of enteritis I have heard words to the effect that "the diarrhœa only lasted a few days and soon cleared up and the patient is quite well; it didn't seem worth sending a specimen." That the patient could have become a possibly dangerous carrier of an intestinal pathogen, and the significance of such a condition if established, had not been appreciated.

Downe, Kent. R. IRENE HUTCHINSON.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—I admire those pioneering surgeons who refuse to be bound by tradition and who try to profit by their observation and experience in devising new methods of treatment. Only this morning with early tea I read from Osler[1]: "Undue reverence for authority as such, a serene satisfaction with the *status quo*, and a fatuous objection to change have often retarded the progress of medicine." But we must be sure that any particular change really means progress.

The statement that some cases of ruptured peptic ulcer recover spontaneously came as no surprise. During the several years that I acted as surgical registrar in the old Newcastle-upon-Tyne Infirmary during the opening years of the century, it was my fortunate lot to make the post-mortem examinations on cases dying in the surgical wards. I recall how often the patient evidences of old inflammatory trouble about the stomach and duodenum, not otherwise explained, suggested the probability of previous perforation. Sometimes the presence of an ulcer or a scar or a typical history was confirmatory. I became so convinced of this possibility that I stated it as an accepted fact in some of my writings (Perforation of the Stomach, &c. *Med. Pr.* Sept. 4, 1912). In those days the mortality in ruptured ulcer was appalling, but just about a year after the publication of that paper I had a clinical experience confirming the truth of the statement.

In August, 1913, I was asked to see an abdominal emergency in a farmer of 60, at his home in what was then a remote part of Northumberland. This man had suffered from stomach trouble for 25 years and had taken "stomach bottles" off and on during the whole of that time. Some 26 hours before my visit and 2 hours after he had vomited a meal, the patient was seized by sudden severe pain with collapse and acute abdominal tenderness. When seen by his own doctor 2 hours afterwards the man was white, cold, collapsed, sweating, and in severe pain. Altogether the condition was very alarming. After a total dose of gr. $^1/_2$ of morphine the patient got relief and sleep.

When I saw the patient next day he was still very ill and looked dusky. The abdomen was not distended but was very tender in the upper part and the liver dullness was completely replaced by a tympanitic note.

We concluded that there had been perforation of a duodenal ulcer. Immediate operation was considered but accommodation in the small farm-house was poor, night was coming on, and candles were the only means of illumination that could be brought to the table. The practitioner and myself were alone, no nurse or other assistant being available, and I had only my small emergency bag with me. To move the patient to Newcastle would have meant a slow tedious railway journey of 46 miles. In view of all these circumstances we decided that the patient would have the better chance if left at home and treated by repeated small doses of morphine with minimal quantities of liquid by mouth.

The patient slowly improved, and a week later was well enough to be moved to Newcastle where an operation was carried out. On opening the abdomen there were unmistakable signs of a leaking duodenal ulcer with local extravasation. The involved area of duodenum was oversewn and gastro-enterostomy performed. After a rather stormy convalescence the man made a complete recovery, and 20 years afterwards, when in his 80th year, he wrote to tell me of his continued good health.

In those days I saw so many disasters associated with the calamity of perforation that I never again had the courage to leave a case without surgical intervention if operation seemed practicable. In some few cases of long-standing perforation the condition was so precarious that it was considered that the chances of recovery would be better with minimal interference, such as the insertion of a suprapubic or right iliac fossa drain, but in every such case the patient died.

While perforation is usually one of the most straightforward diagnoses in abdominal surgery, we must recognise that sometimes it may be very difficult to come to a correct conclusion in spite of all the aids. I have to confess that more than once I have opened the abdomen only to discover that perforation was not present. During the last few years I have seen at least four such cases at Hammersmith Hospital and in two gas was actually demonstrated by the X ray below the diaphragm, and yet subsequent exploration failed to confirm that perforation had occurred.

---

[1] British Medicine in Greater Britain. Aequanimitas. London, 1904.

Further, the very cases in which conservative treatment might be tried are those which yield a small mortality after operation. Yet in a catastrophe fraught with such tragic possibilities it is difficult to predict the exact course of events, and I have lost cases operated on within 6 hours. Nevertheless, as long ago as 1929, with my then assistant, Mr. Norman Hodgson, we had operated on a consecutive batch of 58 cases up to 6 hours after perforation without a death. In the same series there were 144 cases in the 12-hour period with a mortality just under 7 %; and taking all the cases irrespective of the number of hours after perforation there were 209 with a mortality of not quite 15½ %. These figures—and more recent ones are doubtless much better—show that surgeons may expect to deal by operation with large numbers of early perforations with a minimal mortality. It will probably only be in this same group that the problem of treatment without operation arises, so that this plan has a high standard of recovery with which to compete.

But to get the best results the operation must be as simple as possible, "as you cook little fish without much busyness" (Laotze). In the actual management of the operative treatment there are many points worthy of note. I never liked to operate on patients straight off the street, as it were, and an hour or perhaps two spent in preparation is well worth while. Once the decision to operate has been made some relaxing sedative should be given, and for this purpose morphine is the best. In the few cases where the patient feels sick or when a meal has been taken shortly before the calamity it is wise to pass a stomach tube, not for washing out the viscus but for decompression. Unless this can be done easily it should not be persevered with. The morphine helps to overcome rigidity, but in the rare cases where it fails the use of curare during anæsthesia may be successful. General anæsthesia undoubtedly contributes to the unhurried haste with which the operation can be carried out, and in these days it is interesting to recall that when it was my lot to deal with a large amount of emergency work the anæsthesia was of the simplest. We had no special anæsthetists for emergency work and no machines more complicated than the Clover inhaler. Chloroform on lint or open ether on gauze or the Clover fulfilled our needs.

A midline or transrectus incision, big enough not to impede the necessary manipulations for exposing the perforation and to do away with the use of retractors, is essential. The next step is to find the perforation and make it as accessible as possible for suturing. Extravasation, exudate, and loose lymph are mopped away from the vicinity only and the perforation is closed. With regard to the latter step there are sufficient expedients to deal with any combination of circumstances. In most cases up to 6 or even 8 or 10 hours' drainage is not necessary. If there is real need for special haste the parietal incision may safely be closed with through-and-through sutures of strong silkworm or silk (no. 5, Chinese twist).

In these emergencies the simplest life-saving operation, if carried out before peritonitis is established, is so often rewarded by recovery, even in the presence of adverse conditions, that I am apprehensive of any other method that may countenance delay and demand long and anxious supervision. During my not inconsiderable surgical experience—I operated on my first ruptured duodenal ulcer 43 years ago—I have noticed that when some plan other than operation is advocated for acute abdominal conditions it is often seized upon by the profession, and nearly always with a consequent wave of increased mortality or a recovery-rate clouded by much avoidable anxiety. This has certainly been so with regard to appendicitis.

My mind goes back to the days when recovery after ruptured ulcer was a rare event, and now that early surgical intervention yields such great rewards it seems a pity to lightly turn away from the path. It is important that we should learn the real comparative value of the conservative method, but no-one should try the plan unless they are prepared to carry it out thoroughly and conscientiously in all its details. It would really be better if the trial could be left in the hands of a few.

In the meantime do not let us broadcast the conservative method as though a well-established surgical procedure like early operation was already outdated.

Taplow, Bucks. G. GREY TURNER.

SIR ALMROTH WRIGHT AND ANTI-TYPHOID INOCULATION

SIR,—Dr. Douglas Guthrie appears, by his letter of Oct. 19, to give a somewhat grudging assent to the contention that Wright was the originator of anti-typhoid inoculation. Any lingering doubt that remains may be resolved by reference to an article "An investigation upon the blood changes following anti-typhoid inoculation" (Leishman, Harrison, Smallman, and Tulloch) which appeared in the *Journal of Hygiene* (1905, 5, 380). In the introductory paragraphs of that article it is made quite clear that the pioneer work in this field was done by Wright when professor of pathology at the Army Medical School, Netley. While the investigation described in the article was the first systematic one of a long series that led to the adoption of the practice in the British Army with results, in two world wars, that are well known, it was preceded, as shown in the bibliography, by a series of related observations, dating from 1897 onwards, in which Wright was clearly the leading figure.

As the last surviving member of the group which made the investigation referred to above, mere justice to m former colleagues requires that mention be made of the full acknowledgment of the part played by Wright an of the inspiration so characteristic of his work an teaching.

Guildford. A. B. SMALLMAN.

PSYCHONEUROSIS TREATED WITH ELECTRICA CONVULSIONS

SIR,—Dr. W. L. Milligan's article in your issue Oct. 12 requires comment because it gives a wron impression about the relation of psychotherapy electrical-convulsion therapy.

In these days it has become customary to insert articles on the subject a note of caution about the use electrical convulsions and to add a remark about psych therapy somewhere in the discussion; Dr. Milligan is n exception. He employs electrical convulsions for patien that are resistant to "psychotherapeutic measures," an concludes in his summary: "Electro-convulsive therap should not be used indiscriminately; the greatest ca should be taken in selecting cases." But we are give little indication—indeed only the vaguest hints—abou how to select cases; and his case-reports are not helpfu in this respect, because all serious assessment of th personality is lacking.

As I read the article, taking the argument at its fac value, I could not see any reason for Dr. Milligan' caution. There are no ill effects of a serious nature 97 % of the results are favourable and 3 % "no improved." We do not even hear that the 3 % are wors Such evidence does not justify caution, and I am at a los to understand why he expresses these apparentl meaningless sentiments.

The truth of the matter is that once you are prepare to disregard all our knowledge of the nature and structur of the neuroses in relation to the personality as a whol (and Dr. Milligan's paper does this) there is no limit what can be done with neurotic cases. If Dr. Milligan really prepared to disregard our knowledge of psycho pathology, let him say so and let us not have vague tal about cases resistant to "psychotherapeutic measures." To be more specific, which or how many, and in wha combination, does he use the following in his "psycho therapeutic measures": psychological explanations reassurance, re-education, simple suggestion, suggestio under hypnosis, hypnoanalysis, psychoanalysis? Ha he used the methods of indivi alytical psychology, and what about group-therapy, c.?

As it stands, he is like a man who says: "I have tried edicine (without however specifying what kind of edicine), and since that does not work we will try this rgical method" (which he describes accurately). It is uch the same when he uses the word "resistant." If here is a resistance we must know what the patient is esisting: otherwise there is no sense in the word.

For those of us who hold that many neuroses are bortive attempts to cure a diseased mind, Dr. Milligan's esults cannot be assessed. His caution is justified but ot on the grounds of his evidence.

London, N.W.1. MICHAEL FORDHAM.

SIR,—As a consulting physician I have been responsible or referring many patients to Dr. Beaton at St. James ospital, from both private and hospital practice. I ave also been privileged to see some of Dr. Milligan's ases before, during, and after treatment. I can confirm he claims made in his article of Oct. 12. I have yet to ee the mental deterioration or the persistence of the nitial memory defect which have been feared. I am atisfied that it is a most notable advance in helping the sychoneurotic patient.

All new methods should be subjected to the most earching examination and criticism, but this should ot be captious. In these times much routine description must be omitted from articles through lack of space. If Dr. Tooley (Oct. 26) knows the mental-hospital world at all he must realise that in an institution with the reputation of St. James Hospital, Portsmouth, no patient lacks an "adequate examination."

The aim of treatment with the psychoneurotic patient is surely the removal of symptoms. This was achieved in over 90% of cases. The only question is whether the symptoms will stay "removed."

I have read and re-read Dr. Norman Glaister's discursive letter (Oct. 26) and am still unable to grasp its point. He writes disparagingly of five minutes' psychotherapy, yet Dr. Milligan expressly stresses the necessity of adequate psychotherapy in the resynthesis of the personality following treatment.

Southsea. J. C. PRESTWICH.

RUBBER GLOVES

SIR,—I am writing to you hoping that a little publicity may produce some rubber gloves. For the last eight weeks I have been unable to obtain any, and so have had to attend confinements and to operate with bare hands. Fortunately no-one has yet died from septicæmia.

My would-be suppliers inform me that were it rubber contraceptives that I wanted they could supply me by the gross. No doubt the old adage holds good that "prevention is better than cure."

Hove. F. E. GRAHAM-BONNALIE.

TESTIMONIALS

SIR,—The remarks of your peripatetic correspondent of Oct. 26 will interest the many who are trying to find employment in these hard times, and must raise serious *doubts* as to the value of testimonials in securing an appointment.

It is said that a good testimonial will get a man on the short list, and thereafter the final choice depends, inter alia, on the result of the interview. It would be interesting to have the opinion of those qualified to judge on this matter. There is no doubt that the specifically addressed testimonial, or better the personal letter, carries weight in the deserving case, but today the average candidate cannot afford to stand or fall on the result of one application. The result is the open testimonial, which has all the defects of open diplomacy. I have long disliked this document and the asking for it, so reminiscent of the Indian servant wanting his "chit"; since my return to civil life I have neither sought nor submitted a testimonial and am convinced that my progress has not been impeded thereby. I suggest that the submission of a list of names for reference should be more generally adopted since it gives selection committees a better idea of the true worth of a candidate.

Sheffield. LOUIS A. IVES.

G.B. AND N.B.

SIR,—As a not very perfervid Scot I am occasionally annoyed by the misuse of the word England when Britain is meant. However, according to your report (Oct. 26, p. 626), Sir Henry Bashford uses the word Britain for England when he claims that the London Hospital is the largest voluntary hospital in Britain. It seems to me that there is no great merit in mere size, but this claim cannot be sustained. According to the *Hospitals Year Book* for 1943–44 (the last available) the bed complements are: Edinburgh Royal Infirmary 1287, Glasgow Royal Infirmary 980, London Hospital 891.

A. A. MACIVER
Royal Infirmary, Glasgow. Secretary.

*** We are glad of the correction. Sir Henry joins us in apology.—ED. L.

THIOUREA DERIVATIVES IN THYROTOXICOSIS

SIR,—A note in your issue of Sept. 7 (p. 368) says that there appear to be no published reports of agranulocytosis in patients treated with methyl thiouracil. This is not correct. Kristiansen (*Ugeskr. Læg.* 1945, 107, 255), Leschley Jacobsen (*Ibid*, p. 721), and Ehlertsen (*Ibid*, 1946, 108, 192) have each published a case with recovery, and Lundbæk has published a fatal case (*Ibid*, 1945, 107, 253). Ehlertsen, who made a tentative comparison of the side-effects of thiouracil and methyl thiouracil (and thiourea), saw no conclusive difference between the two first-named.

Aarhus, Denmark. C. HOLTEN.

Public Health

The Third Quarter

DURING the September quarter of this year 213,135 live births were registered, representing a birth-rate of 19·7, the highest recorded in any quarter since June, 1923. This maintains the upward tendency shown in the June quarter, when the number of births registered was 203,797.

The births and deaths registered during the September quarter, with figures for the corresponding quarters of 1945 and 1938, are as follows:

	Live births		Stillbirths		Deaths, including non-civilians	
	Number	Per 1000 popn.	Number	Per 1000 popn.	Number	Per 1000 popn.
Third quarter, 1946	213,135	19·7	5778	0·53	100,363	9·3
" " 1945	167,807	15·6	4676	0·44	97,159	9·0
" " 1938	158,082	15 2	6072	0·58	102,545	9·9

The birth-rate of 19·7 is 4·1 above that for the third quarter of 1945, and 4·5 above that for the corresponding quarter of 1938, the last complete pre-war year. The average for the September quarters of the years 1940–44 was 15·4.

Infectious Disease in England and Wales

WEEK ENDED OCT. 26

Notifications.—Smallpox, 0; scarlet fever, 1209; whooping-cough, 1499; diphtheria, 314; paratyphoid, 89 (71 at Sheffield); typhoid, 9; measles (excluding rubella), 2884; pneumonia (primary or influenzal), 436; cerebrospinal fever, 28; poliomyelitis, 31; polioencephalitis, 2; encephalitis lethargica, 1; dysentery, 59; puerperal pyrexia, 160; ophthalmia neonatorum 68. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on Oct. 23 was 878. During the previous week the following cases were admitted: scarlet fever, 56; diphtheria, 21; measles, 17; whooping-cough, 43.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (1) from enteric fever, 2 (0) from measles, 4 (0) from whooping-cough, 3 (0) from diphtheria, 36 (4) from diarrhœa and enteritis under two years, and 13 (1) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 265 (corresponding to a rate of 29 per thousand total births), including 26 in London.

Parliament

NATIONAL HEALTH SERVICE BILL

Third Reading in the Lords

ON Oct. 31 the LORD CHANCELLOR, in moving the third reading, regretted that the Government had not found it possible to frame an amendment to meet the wishes of Viscount Cecil of Chelwood in regard to the treatment of deafness. The noble Viscount had wanted a provision inserted after clause 41 which dealt with supplementary services. This matter of the ear, however, Lord Jowitt pointed out, was not like that of the eye, for anyone who wanted spectacles could go to an ophthalmic optician, but if he had anything the matter with his ears he should go to a properly qualified doctor. If ears could not come as a supplementary service they should come as part of the general hospital service under clause 3, where the Minister was under a duty to provide for "medical, nursing, and other services required at or for the purposes of hospitals," and "the services of specialists, whether at a hospital, a health centre . . . or a clinic." If he were to put in particularly deafness then he was sure that Lord Horder would want to put in rheumatism, and others of their Lordships would want to put in other things until they had set out a whole chain and achieved nothing. After consulting the Minister, Lord Jowitt repeated the definite assurance that a comprehensive service would include provision for deafness. By that he meant not merely the trained assistants that would be required, but also the provision of instruments to alleviate deafness. He would take up with the President of the Board of Trade the question of the production and price of deaf-aids. He regarded it as most important that such instruments should be produced in as large numbers as possible at the earliest possible date, and that they should be available to the public free of charge.

THE AMENDMENTS

Turning to the amendments which had been accepted by the Government, Lord Jowitt said he hoped their Lordships would not take these as showing any weakening or lack of resolution or courage. On the contrary, he thought that the Minister had shown good sense and judgment in meeting the wishes of the House. The main part of the alterations had the effect of writing into the Bill undertakings given by the Minister. One illustration was the amendment dealing with the denominational hospitals, and he could give the assurance that the administration of the matter by the Minister would be in no niggardly or reluctant spirit. He was also glad that the Government had been able to hit upon a method of dealing with endowments which met the general wishes of the House. It did not interfere with the general principle that endowments were to be devoted to all hospitals, but it protected specific endowments intended for particular purposes. He thought it was also a good thing that the powers of the hospital management committee should have been set out in the way they now appeared in the Bill. He might be right or wrong, but personally he took the view that the position in regard to the discovery of documents had already been safeguarded.

Only one alteration of real substance had been made, that affecting the time between the appointed day and the passing of the Act, which might be as long as 18 months. The Minister had already arranged that after the appointed day endowments given to a particular hospital should not be taken away from that institution. That principle had now been extended to the interval of time directly after the Bill became an Act.

TWO BLEMISHES

Lord Jowitt confessed that he thought the Bill had two blemishes. Their Lordships, in his view, were wrong in saying that no part of a doctor's remuneration should be by way of salary. From his experience as Minister of National Insurance he realised that the success or failure of all these schemes depended largely on satisfactory certification. If there was lax or, still more, dishonest certification all these schemes would break on that rock. He had a profound regard for the medical profession, and for their standard of honour, but he had come across cases, not many, where there were two competing doctors, one strict and the other lax in the certification. The people on the panel of the strict doctor were inclined to leave him and go to the other doctor who was lax, not because the latter was a better doctor but because they could more easily get certificates. If the per capita payment had been abolished altogether, and there had been a straight out-and-out salary, the temptation would have gone. But he did not for a moment suggest that, because it would have brought in other troubles and would not have been practical politics. But to have given something in the way of salary would have been valuable, and he honestly believed that their Lordships had made a great mistake. The other blemish was the special *treatment* of London. It was a great pity that health services should be split between two authorities. For the rest, Lord Jowitt claimed that the Government had preserved the absolute right of choice of doctor. They were not going to force anybody to take a doctor he did not like. Nor was it their intention, as some nurses feared, to move people about in the regions. Anyone who had a contract to serve in a particular place could only be called on to serve there. Under this new health scheme there would still be great scope for voluntary service and he hoped that the passing of the Bill would not prevent such service from being forthcoming.

SOME IMPROVEMENTS

Lord LLEWELLIN thought that in their six days' work their Lordships had improved the Bill. One important change was that it had been made certain that a doctor—whether acting in an honorary capacity or not—who served on the staff of one hospital might get his patient admitted, or might even treat him in another hospital. Although Lord Llewellin agreed that there should be a large hospital unit he hoped that the smaller hospitals in the country towns would not be closed, because they still had a useful function in attending to minor ailments which did not require the special treatment of the larger regional hospitals.

The amendments in regard to endowments would, he thought, allow of continuity of voluntary gifts, and maintain the continuity of memory when a gift was made for a specific purpose. The words "control and manage" now inserted into the Bill gave the hospital management committees a better function, and it was, Lord Llewellin held, important that these bodies should not represent mere titles but should have *obvious* powers. He hoped the amendment making these committees capable of suing and of being sued would become part of the Bill. He was also grateful for the assurances given that doctors would have adequate notice of the conditions of service before the appointed day, and that in a proper case a relative should be given a reasonable chance of succeeding to a practice.

There was, he felt, much to be said for the Minister having the last word whether a doctor should continue in the service. But he thought the Bill had been improved by strengthening the doctor's rights before the tribunals.

THE CAPITATION FEE

His amendment in regard to the doctor's remuneration, Lord Llewellin pointed out, left exceptional cases to be dealt with by salary and capitation fee. It had never yet been stated what, in the new service, would be the normal proportion between salary and capitation

If the Government did not see their way to accept e Lords' amendment they should say what proportion ey had in mind. There were obvious things to be said gainst the capitation fee if it meant doctors taking on ore patients than they could properly handle, or getting atients because they were slightly lax in giving certificates. But by and large it was undesirable to take away rom doctors the sense of energy and hard work, and art of that depended upon their being able to attract atients by giving good service.

The Marquess of **Reading** agreed with the Lord hancellor in thinking that the amendment establishing ayment for doctors purely by capitation fees was a lemish on the measure. He hoped that method of payment would not be eventually embodied in the Bill.

Lord **Balfour of Burleigh** said it would be a tribute to the good sense and judgment of the Minister if he saw fit to accept the amendment inserted in the Bill in regard to the London boroughs and their health services. The two major objectives of the amendment were to maintain the high quality of the maternity and child-welfare services in the boroughs, and to cease the process of undermining the quality of local government in the whole of the metropolitan boroughs. Both would be in serious danger if that amendment was not allowed to remain in the Bill. If the services were transferred to the L.C.C. the personal touch would be lost.

The Bill was read the third time with the amendments, passed, and returned to the Commons.

The Lords' Amendments in the Commons

On Nov. 4 the House of Commons met to consider the amendments made to the National Health Service Bill in the House of Lords.

FUNCTIONS OF THE METROPOLITAN BOROUGHS

In moving that "this House doth disagree with the Lords" in the amendment permitting the transfer of some health services from the London County Council to the metropolitan boroughs, Mr. C. S. **Key** pointed out that it destroyed the coördination of the personal health services in London. The amendment would make a serious break in child-welfare work; for the care of the over-fives and of the under-fives in the nursery schools would go to the L.C.C., while the care of the under-fives at the day nurseries would be under the borough council. Prenatal and postnatal services would come under the boroughs, but it would be the L.C.C.'s responsibility to provide the midwives and maternity nurses. Again the borough councils would have to provide home nursing and domestic help in cases of illness, but preventive and aftercare services would still be dealt with by the L.C.C. The amendment gave the borough councils power to maintain maternity and child-welfare centres, but left with the L.C.C. the development of the health centres. The Bill aimed at setting up common health centres where there could be common knowledge among the people serving of each particular case. The unified service set up by the Bill would mean that a service of common standards would be provided for all areas in London irrespective of their poverty or wealth, whereas the amendment laid down that half of the cost of the services was to be provided by the borough council. As a Londoner he was proud to ask the House in the interests of London to disagree with the Lords in their amendment.

Mr. R. **Law** argued that the principles of absolute uniformity did not run all through the Bill itself. Expectant mothers and health centres, for example, both came under several authorities. If there was anything in this argument it was that the whole Bill and not this amendment by itself was unworkable.

Mr. **Somerville Hastings** thought the amendment would at least have been intelligible if it transferred all the health functions to the borough councils. As it was it would merely increase the number of health authorities in London from three to four. Under the Bill the L.C.C. was to be the authority for health centres, and he was sure it was the Minister's intention to associate all the doctors in the new service with the prevention of disease. One way was to get them to work in health centres where the preventive services were being carried out in closest contact with health visitors, maternity and child-welfare clinics, and home nursing services. Yet the amendment wanted to put these services under the borough councils which would have nothing to do with the health centres, and would indeed have power to provide separate premises for their services. The amendment would thus separate more than was necessary the preventive and curative sides of the treatment of disease.

Mr. **Bevan** described the discussion which followed as a fairly long one during which nothing new was heard. He pointed out that the amendment would give rise to as many anomalies as it sought to correct, for the anomalies were inherent in our local-government structure. Harrow, for example, had a population of 211,000, but the withers of the Opposition remained unwrung, though they were speechless with indignation about Holborn with a population of 22,000. He agreed that the accessibility of the local authority to the population was of the utmost importance, but in future the citizen who was in difficulty about his health would go to the health centre and not to the town hall. At the centre he could have all his wants attended to in the same place by the same organisation. These schemes had been carefully integrated and Mr. Bevan felt bound to pray of the House not to make a radical alteration at that stage.

The amendment was negatived by 296 votes to 134.

BASIC SALARY

Mr. **Bevan** resisted the Lords' amendment that the remuneration of general practitioners under the new scheme should normally be by capitation fee. He had heard arguments for and against the basic salary but he had never yet heard an argument why it should be put in the Bill. It was not desirable for future negotiations with the medical profession to start with a statutory inhibition. He therefore seriously suggested to Members in all parts of the House that whatever their views about having a basic element in the remuneration they should not insist upon its going into the Bill but should leave it open.

He was not seeking to escape a discussion of the main issue, but he wished to face it forthrightly. By the abolition of the sale of practices the young doctor had been delivered from the hands of the moneylenders, but he had not been provided with a positive means of livelihood. It was therefore the Government's intention that while the young general practitioner was building up his list he should have the security of a salary. He could not accept the view that a doctor examined his patients any better if his heart was gnawed with financial anxiety. A basic salary would reduce competition for patients, and the build-up of panel lists had not always been done by methods which commended themselves to the best elements of the medical profession. Another reason in favour of a basic salary was that the remuneration of a doctor should contain an element to which inducements for special training and qualifications could be added. It had been suggested that they could add to the capitation fee, but that would be very untidy and almost impossible.

Some doctors feared that this was the beginning of a full-time salaried service. Mr. Bevan said he could not read into the mind of any future Minister, but that was not his own intention. The Government intended that the main source of a doctor's remuneration should be by *capitation*, and for excellent reasons. There was an argument for having a full-time salaried service; *there* was an argument for having full capitation; but there was no argument for having a high basic salary

Parliament

NATIONAL HEALTH SERVICE BILL

Third Reading in the Lords

ON Oct. 31 the LORD CHANCELLOR, in moving the third reading, regretted that the Government had not found it possible to frame an amendment to meet the wishes of Viscount Cecil of Chelwood in regard to the treatment of deafness. The noble Viscount had wanted a provision inserted after clause 41 which dealt with supplementary services. This matter of the ear, however, Lord Jowitt pointed out, was not like that of the eye, for anyone who wanted spectacles could go to an ophthalmic optician, but if he had anything the matter with his ears he should go to a properly qualified doctor. If ears could not come as a supplementary service they should come as part of the general hospital service under clause 3, where the Minister was under a duty to provide for "medical, nursing, and other services required at or for the purposes of hospitals," and "the services of specialists, whether at a hospital, a health centre . . . or a clinic." If he were to put in particularly deafness then he was sure that Lord Horder would want to put in rheumatism, and others of their Lordships would want to put in other things until they had set out a whole chain and achieved nothing. After consulting the Minister, Lord Jowitt repeated the definite assurance that a comprehensive service would include provision for deafness. By that he meant not merely the trained assistants that would be required, but also the provision of instruments to alleviate deafness. He would take up with the President of the Board of Trade the question of the production and price of deaf-aids. He regarded it as most important that such instruments should be produced in as large numbers as possible at the earliest possible date, and that they should be available to the public free of charge.

THE AMENDMENTS

Turning to the amendments which had been accepted by the Government, Lord Jowitt said he hoped their Lordships would not take these as showing any weakening or lack of resolution or courage. On the contrary, he thought that the Minister had shown good sense and judgment in meeting the wishes of the House. The main part of the alterations had the effect of writing into the Bill undertakings given by the Minister. One illustration was the amendment dealing with the denominational hospitals, and he could give the assurance that the administration of the matter by the Minister would be in no niggardly or reluctant spirit. He was also glad that the Government had been able to hit upon a method of dealing with endowments which met the general wishes of the House. It did not interfere with the general principle that endowments were to be devoted to all hospitals, but it protected specific endowments intended for particular purposes. He thought it was also a good thing that the powers of the hospital management committee should have been set out in the way they now appeared in the Bill. He might be right or wrong, but personally he took the view that the position in regard to the discovery of documents had already been safeguarded.

Only one alteration of real substance had been made, that affecting the time between the appointed day and the passing of the Act, which might be as long as 18 months. The Minister had already arranged that after the appointed day endowments given to a particular hospital should not be taken away from that institution. That principle had now been extended to the interval of time directly after the Bill became an Act.

TWO BLEMISHES

Lord Jowitt confessed that he thought the Bill had two blemishes. Their Lordships, in his view, were wrong in saying that no part of a doctor's remuneration be by way of salary. From his experience as of National Insurance he realised that the succe failure of all these schemes depended largely on sa factory certification. If there was lax or, still mo dishonest certification all these schemes would bre on that rock. He had a profound regard for the medi profession, and for their standard of honour, but he h come across cases, not many, where there were t competing doctors, one strict and the other lax in th certification. The people on the panel of the strict doct were inclined to leave him and go to the other doct who was lax, not because the latter was a better doct but because they could more easily get certificate If the per capita payment had been abolished altogethe and there had been a straight out-and-out salary, th temptation would have gone. But he did *not for a moment* suggest that, because it would have brought in other troubles and would not have been practical politics. But to have given something in the way of salary would have been valuable, and he honestly believed that their Lordships had made a great mistake. The other blemish was the special treatment of London. It was a great pity that health services should be split between two authorities. For the rest, Lord Jowitt claimed that the Government had preserved the absolute right of choice of doctor. They were not going to force anybody to take a doctor he did not like. Nor was it their intention, as some nurses feared, to move people about in the regions. Anyone who had a contract to serve in a particular place could only be called on to serve there. Under this new health scheme there would still be great scope for voluntary servic and he hoped that the passing of the Bill would no prevent such service from being forthcoming.

SOME IMPROVEMENTS

Lord LLEWELLIN thought that in their six days' work their Lordships had improved the Bill. On important change was that it had been made certain that a doctor—whether acting in an honorary capacity or not—who served on the staff of one hospital might get his patient admitted, or might even treat him in another hospital. Although Lord Llewellin agreed that there should be a large hospital unit he hoped that the smaller hospitals in the country towns would not be closed, because they still had a useful function in attending to minor ailments which did not require the special treatment of the larger regional hospitals.

The amendments in regard to endowments would, he thought, allow of continuity of voluntary gifts, an maintain the continuity of memory when a gift was mad for a specific purpose. The words "control and manage now inserted into the Bill gave the hospital management committees a better function, and it was, Lor Llewellin held, important that these bodies should no represent mere titles but should have obvious powers He hoped the amendment making these committee capable of suing and of being sued would become pa of the Bill. He was also grateful for the assurance given that doctors would have adequate notice of th conditions of service before the appointed day, and tha in a proper case a relative should be given a reasonabl chance of succeeding to a practice.

There was, he felt, much to be said for the Ministe having the last word whether a doctor should continu in the service. But he thought the Bill had been improve by strengthening the doctor's rights before the tribunals

THE CAPITATION FEE

His amendment in regard to the doctor's remuneration, Lord Llewellin pointed out, left exceptional case to be dealt with by salary and capitation fee. It had never yet been stated what, in the new service, would be the normal proportion between salary and capitation

If the Government did not see their way to accept Lords' amendment they should say what proportion ey had in mind. There were obvious things to be said ainst the capitation fee if it meant doctors taking on ore patients than they could properly handle, or getting atients because they were slightly lax in giving certifi- ates. But by and large it was undesirable to take away om doctors the sense of energy and hard work, and art of that depended upon their being able to attract atients by giving good service.

The Marquess of **Reading** agreed with the Lord hancellor in thinking that the amendment establishing ayment for doctors purely by capitation fees was a lemish on the measure. He hoped that method of ayment would not be eventually embodied in the Bill.

Lord **Balfour of Burleigh** said it would be a tribute o the good sense and judgment of the Minister if he saw it to accept the amendment inserted in the Bill in regard o the London boroughs and their health services. The wo major objectives of the amendment were to maintain he high quality of the maternity and child-welfare ervices in the boroughs, and to cease the process of ndermining the quality of local government in the whole of the metropolitan boroughs. Both would be in serious langer if that amendment was not allowed to remain in the Bill. If the services were transferred to the L.C.C. the personal touch would be lost.

The Bill was read the third time with the amendments, passed, and returned to the Commons.

The Lords' Amendments in the Commons

On Nov. 4 the House of Commons met to consider the amendments made to the National Health Service Bill in the House of Lords.

FUNCTIONS OF THE METROPOLITAN BOROUGHS

In moving that "this House doth disagree with the Lords" in the amendment permitting the transfer of some health services from the London County Council to the metropolitan boroughs, Mr. C. S. **Key** pointed out that it destroyed the coördination of the personal health services in London. The amendment would make a serious break in child-welfare work; for the care of the over-fives and of the under-fives in the nursery schools would go to the L.C.C., while the care of the under-fives at the day nurseries would be under the borough council. Prenatal and postnatal services would come under the boroughs, but it would be the L.C.C.'s responsibility to provide the midwives and maternity nurses. Again the borough councils would have to provide home nursing and domestic help in cases of illness, but preventive and aftercare services would still be dealt with by the L.C.C. The amendment gave the borough councils power to maintain maternity and child-welfare centres, but left with the L.C.C. the development of the health centres. The Bill aimed at setting up common health centres where there could be common knowledge among the people serving of each particular case. The unified service set up by the Bill would mean that a service of common standards would be provided for all areas in London irrespective of their poverty or wealth, whereas the amendment laid down that half of the cost of the services was to be provided by the borough council. As a Londoner he was proud to ask the House in the interests of London to disagree with the Lords in their amendment.

Mr. R. **Law** argued that the principles of absolute uniformity did not run all through the Bill itself. Expectant mothers and health centres, for example, both came under several authorities. If there was anything in this argument it was that the whole Bill and not this amendment by itself was unworkable. Mr. **Somerville Hastings** thought the amendment would at least have been intelligible if it transferred all the health functions to the borough councils. As it was it would merely increase the number of health authorities in London from three to four. Under the Bill the L.C.C. was to be the authority for health centres, and he was sure it was the Minister's intention to associate all the doctors in the new service with the prevention of disease. One way was to get them to work in health centres where the preventive services were being carried out in closest contact with health visitors, maternity and child-welfare clinics, and home nursing services. Yet the amendment wanted to put these services under the borough councils which would have nothing to do with the health centres, and would indeed have power to provide separate premises for their services. The amendment would thus separate more than was necessary the preventive and curative sides of the treatment of disease.

Mr. **Bevan** described the discussion which followed as a fairly long one during which nothing new was heard. He pointed out that the amendment would give rise to as many anomalies as it sought to correct, for the anomalies were inherent in our local-government structure. Harrow, for example, had a population of 211,000, but the withers of the Opposition remained unwrung, though they were speechless with indignation about Holborn with a population of 22,000. He agreed that the accessibility of the local authority to the population was of the utmost importance, but in future the citizen who was in difficulty about his health would go to the health centre and not to the town hall. At the centre he could have all his wants attended to in the same place by the same organisation. These schemes had been carefully integrated and Mr. Bevan felt bound to pray of the House not to make a radical alteration at that stage.

The amendment was negatived by 296 votes to 134.

BASIC SALARY

Mr. **Bevan** resisted the Lords' amendment that the remuneration of general practitioners under the new scheme should normally be by capitation fee. He had heard arguments for and against the basic salary but he had never yet heard an argument why it should be put in the Bill. It was not desirable for future negotiations with the medical profession to start with a statutory inhibition. He therefore seriously suggested to Members in all parts of the House that whatever their views about having a basic element in the remuneration they should not insist upon its going into the Bill but should leave it open.

He was not seeking to escape a discussion of the main issue, but he wished to face it forthrightly. By the abolition of the sale of practices the young doctor had been delivered from the hands of the moneylenders, but he had not been provided with a positive means of livelihood. It was therefore the Government's intention that while the young general practitioner was building up his list he should have the security of a salary. He could not accept the view that a doctor examined his patients any better if his heart was gnawed with financial anxiety. A basic salary would reduce competition for patients, and the build-up of panel lists had not always been done by methods which commended themselves to the best elements of the medical profession. Another reason in favour of a basic salary was that the remuneration of a doctor should contain an element to which inducements for special training and qualifications could be added. It had been suggested that they could add to the capitation fee, but that would be very untidy and almost impossible.

Some doctors feared that this was the beginning of a full-time salaried service. Mr. Bevan said he could not read into the mind of any future Minister, but that was not his own intention. The Government intended that the main source of a doctor's remuneration should be by capitation, and for excellent reasons. There was an argument for having a full-time salaried service; there was an argument for having full capitation; but there was no argument for having a high basic salary

Parliament

NATIONAL HEALTH SERVICE BILL

Third Reading in the Lords

On Oct. 31 the **Lord Chancellor**, in moving the third reading, regretted that the Government had not found it possible to frame an amendment to meet the wishes of Viscount Cecil of Chelwood in regard to the treatment of deafness. The noble Viscount had wanted a provision inserted after clause 41 which dealt with supplementary services. This matter of the ear, however, Lord Jowitt pointed out, was not like that of the eye, for anyone who wanted spectacles could go to an ophthalmic optician, but if he had anything the matter with his ears he should go to a properly qualified doctor. If ears could not come as a supplementary service they should come as part of the general hospital service under clause 3, where the Minister was under a duty to provide for "medical, nursing, and other services required at or for the purposes of hospitals," and "the services of specialists, whether at a hospital, a health centre . . . or a clinic." If he were to put in particularly deafness then he was sure that Lord Horder would want to put in rheumatism, and others of their Lordships would want to put in other things until they had set out a whole chain and achieved nothing. After consulting the Minister, Lord Jowitt repeated the definite assurance that a comprehensive service would include provision for deafness. By that he meant *not merely the trained assistants that would be required*, but also the provision of instruments to alleviate deafness. He would take up with the President of the Board of Trade the question of the production and price of deaf-aids. He regarded it as most important that such instruments should be produced in as large numbers as possible at the earliest possible date, and that they should be available to the public free of charge.

THE AMENDMENTS

Turning to the amendments which had been accepted by the Government, Lord Jowitt said he hoped their Lordships would not take these as showing any weakening or lack of resolution or courage. On the contrary, he thought that the Minister had shown good sense and judgment in meeting the wishes of the House. The main part of the alterations had the effect of writing into the Bill undertakings given by the Minister. One illustration was the amendment dealing with the denominational hospitals, and he could give the assurance that the administration of the matter by the Minister would be in no niggardly or reluctant spirit. He was also glad that the Government had been able to hit upon a method of dealing with endowments which met the general wishes of the House. It did not interfere with the general principle that endowments were to be devoted to all hospitals, but it protected specific endowments intended *for particular purposes*. He thought it was also a good thing that the powers of the hospital management committee should have been set out in the way they now appeared in the Bill. He might be right or wrong, but personally he took the view *that* the position in regard to the discovery of documents had already been safeguarded.

Only one alteration of real substance had been made, that affecting the time between the appointed day and the passing of the Act, which might be as long as 18 months. The Minister had already arranged that after the appointed day endowments given *to a particular* hospital should not be taken away from that institution. That principle had now been extended to the interval of time directly after the Bill became an Act.

TWO BLEMISHES

Lord Jowitt confessed that he thought the Bill had two blemishes. Their Lordships, in his view, were wrong in saying that no part of a doctor's remuneration be by way of salary. From his experience as of National Insurance he realised that the succes failure of all these schemes depended largely on sa factory certification. If there was lax or, still m dishonest certification all these schemes would br on that rock. He had a profound regard for the med profession, and for their standard of honour, but he come across cases, not many, where there were competing doctors, one strict and the other lax in th certification. The people on the panel of the strict doct were inclined to leave him and go to the other doct who was lax, not because the latter was a better doc but because they could more easily get certificate If the per capita payment had been abolished altogethe and there had been a straight out-and-out salary, th temptation would have gone. But he did not for moment suggest that, because it would have brough in other troubles and would not have been practica politics. But to have given something in the way o salary would have been valuable, and he honestl believed that their Lordships had made a grea mistake. The other blemish was the special treatmen of London. It was a great pity that health service should be split between two authorities. For the rest Lord Jowitt claimed that the Government had preserve the absolute right of choice of doctor. They were no going to force anybody to take a doctor he did not like Nor was it their intention, as some nurses feared, t *move people about in the regions.* Anyone who had contract to serve in a particular place could only b called on to serve there. Under this new health schem there would still be great scope for voluntary servi and he hoped that the passing of the Bill would n prevent such service from being forthcoming.

SOME IMPROVEMENTS

Lord **Llewellin** thought that in their six day work their Lordships had improved the Bill. O important change was that it had been made certain th a doctor—whether *acting in an* honorary capac or not—who served on the staff of one hospital mig get his patient admitted, or might even treat him i another hospital. Although Lord Llewellin agreed th there should be a large hospital unit he hoped that t smaller hospitals in the country towns would not closed, because they still had a useful function in atten ing to minor ailments which did not require the speci treatment of the larger regional hospitals.

The amendments in regard to endowments would, thought, allow of continuity of voluntary gifts, a maintain the continuity of memory when a *gift* was ma for a specific purpose. The words "control and manage now inserted into the Bill gave the hospital manag ment committees a better function, and it was, Lo Llewellin held, important that these bodies should n *represent mere titles but should have obvious power* He hoped the amendment making these committe capable of suing and of being sued would become pa of the Bill. He was also grateful for the assuranc given that doctors would have adequate notice of t conditions of service before the appointed day, and th in a proper case a relative should be given a reasonal chance of succeeding to a practice.

There was, he felt, much to be said for the Minist having the last word whether a doctor should contin in the service. But he thought the Bill had been improv *by strengthening the doctor's rights* before the tribuna

THE CAPITATION FEE

His amendment in regard to the doctor's remuner tion, Lord Llewellin pointed out, left exceptional cas to be dealt with by salary and capitation fee. It ha never yet been stated what, in the new service, wou be the normal proportion between salary and capitatio ealth Insurance. He suggested that the Minister might ve an undertaking that, if the Spens report showed at the present dental scale was inadequate, retrospective yments would be made from the time of this dispute.

Mr. JAMES GRIFFITHS, Minister of National Insurance, id the system of unequal benefits to insured persons as going, and ought to go. Whatever settlement was ade now could only be temporary pending the introducon of the National Health Service scheme in 1948. the meantime, Mr. Griffiths continued, he and the linister of Health had to decide not what they thought ne dentist ought to have but the scale of fees which he approved societies could meet. If there was not nough money to meet half the cost there could be no ervice. The approved societies had only a limited mount of money for this purpose, and it would cheat he insured people of this country if he as Minister pproved a scale giving the dentists an increase in emuneration which the approved societies could not meet. He claimed that the Government were entitled to take the view that, apart from the fact that the acceptance of the suggested new scale would have meant a breakdown of the system, it involved such a radical departure from the old scale that it would prejudge the very issues which the Spens Committee had been appointed to investigate. It was in the interests of the dentists to rejoin the committee so that it might be able to go on with its work and report quickly. In 18 months the whole of the present system would go, and Mr. Griffiths would be glad to be one who pushed it out. But for the next 18 months he had the responsibility of seeing that the old system carried on, and anything he accepted was of no value unless the approved societies could work it.

QUESTION TIME

Milk Distribution

Sir HENRY MORRIS-JONES asked the Minister of Food what as the total quantity of milk distributed per week to nonriority users and how much to priority users, stating the tal amount for each category; and what was the average mount of milk per person bought, distributed, or consumed re-war.—Mr. JOHN STRACHEY replied: The total weekly uantity of milk distributed to different categories of conmers cannot be precisely stated, but the total quantities uthorised for non-priority users in Great Britain when the tandard weekly allowance is 2 pints per week are approximately 9½ million gallons and for priority users approximately 0½ million gallons. The weekly quantities authorised for the ifferent categories are as follows:

Non-priority	*Gallons*
Registered customers over 18 years	7,390,000
Non-priority establishments—e.g., canteens, restaurants, groups of industrial, business, and clerical workers	2,200,000
	9,500,000
Priority	
Registered customers, under 5 years	2,900,000
" " 5 to 18 years	3,300,000
Expectant mothers	600,000
Mothers of children under 1 year	300,000
Invalids suffering from conditions which qualify for extra milk	1,300,000
Priority establishments—e.g., hospitals, schools, and milk-in-schools scheme	2,100,000
	10,500,000

During September, when the non-priority allowance was 2 pints per week, the total amount of liquid milk actually distributed was 99·06 million gallons, or a weekly average of 23·114 million gallons.

For the years 1937 to 1939 inclusive the average weekly consumption of milk in England and Wales was 3·01 pints per head. For the year October, 1945, to September, 1946, the average consumption was 4·62 pints per head per week.

Approved Societies and Dental Benefit

Sir WILLIAM DARLING asked the Minister of National Insurance the total number of approved societies; the number paying dental benefit; and the total amount of funds hypothecated for dental benefit.—Mr. T. STEELE replied: The total number of approved societies and branches which constitute separate units for valuation purposes is about 6000; about 5000 of these have schemes of additional benefits which include dental benefit. The total annual allocation of funds for the provision of this benefit is approximately £2,400,000.

Obituary

WILFRID FOSTER VIRET

D.S.C., M.R.C.S.

Wilfrid Viret died at Bradford on Oct. 23 after a short illness. The second son of the late Dr. B. P. Viret, of Bradford, he was 36 years of age and was educated at the Bradford Grammar School, Leeds University, and University College Hospital. After qualifying in 1935 he was house-physician at Leeds General Infirmary and then took a short-service commission in the Royal Navy. He spent some years on the China Station, most of them in the river gunboat H.M.S. *Tern*. He saw something of the Sino-Japanese war and on a number of occasions attended civilian casualties after air-raids by the Japanese. Before his five years' term of service came to an end, war broke out in 1939 and he continued to serve in the Navy. In the early part of the war he was surgeon lieutenant in the destroyer H.M.S. *Vesper*, engaged in the Channel patrol; but later he was transferred to the cruiser H.M.S. *Aurora* and spent some years in the Mediterranean theatre of war. In 1941 he was awarded the Distinguished Service Cross for conspicuous bravery and devotion to duty.

On demobilisation last December Viret went into practice at Shipley, in Yorkshire, with his brother and sister-in-law. He bade fair to become the ideal family doctor, and was looking forward to a useful life in the English country to which he was devoted, his plans being divided between the Yorkshire Dales and Somerset. "A sturdy handsome man with a peculiarly deep resonant voice and a lively personality, his tastes were for simple things, good books and conversation, old furniture and glass. But above all he loved his home life, of which he had all too little during his ten years in the Royal Navy. He liked to potter about in a kitchen and cook unusual and tasty meals. His flair for cooking dated from boyhood, and at the age of nine he would cook the meals of his fellow wolf-cubs. His well-filled and alert mind caused him to write a clear and vigorous prose style, his letters from abroad being full of shrewd and witty observations of people, places, and affairs, illustrated often by thumbnail sketches characterised by economy of line."

In 1940 he married Penelope Mary Downes, and he leaves a son and daughter.

STUART McDONALD

M.A., M.D. CAMB., PH.D. BIRM.

Prof. Stuart McDonald, jun., who died on Oct. 24 at the early age of 41, was one of the most brilliant of the younger pathologists.

The only son of Prof. Stuart McDonald, formerly professor of pathology at Durham, he was educated at Fettes and at Caius College, Cambridge, where he graduated B.A. in 1926. He received his clinical training at Edinburgh and Newcastle-upon-Tyne, qualifying in 1930. For the next four years he was demonstrator in pathology at Durham and assistant pathologist to the Royal Victoria Infirmary, Newcastle-upon-Tyne. In 1934 he went to Birmingham as senior lecturer in pathology and assistant pathologist to the General Hospital, and he was later appointed histologist to the Birmingham branch of the British Empire Cancer Campaign. Both at Durham and Birmingham he was actively engaged in research, as is shown by his many publications on a variety of subjects. He graduated M.D. in 1938, and the following year received the degree of PH.D. at Birmingham.

Always interested in military training, McDonald had received a commission in the Territorial Army in 1932, and for a time commanded the medical unit of Durham University S.T.C. In 1936 he was given the mobilisation appointment of deputy assistant director of pathology.

and a small capitation, because the higher the basic element the more it became concealed capitation; for after the lists had reached the point where they absorbed the basic element, it was merely another form of capitation payment. If the basic element was too high they would find it difficult to carry out the recommendations of the Spens report. If the basic salary was too high obviously the capitation-rate would have to be lower, and the higher salaries recommended for successful general practitioners could not be achieved without unduly large lists. The fears of the medical profession were unfounded, and Mr. Bevan reaffirmed that it was not proposed that the basic element should be the main part of the remuneration.

Mr. J. S. C. **Reid** declared that the Minister's calming assurances had no value unless Labour Party policy had been altered in the last three or four months. No-one suggested that there should not be a salary in areas of scattered population or that there could not be a fixed small payment for special qualifications. At present the medical profession were free and independent because the majority of doctors were free and independent. But as soon as the majority received a salary he believed the atmosphere would change. Mr. C. H. **Gage** said that the medical profession had many great things to offer—integrity, high standards, and ideals. But it did not at present offer a sheltered and secure life. In that lay its strength. If the Minister gave it security he might take away something which was far more valuable—its high standards.

Sir **Henry Morris-Jones** thought that if the capitation system was adopted the medical profession would be much more inclined to look favourably at the scheme. The salary basis would reduce the whole thing to a dull level of uniformity and the profession would lose the colour and characteristics which are the foundation of medicine. Dr. S. **Segal** doubted whether insecurity was always an incentive. Some doctors born into this world in a state of security were able to specialise. He hoped the Bill would ensure that other deserving elements of the community would not be deprived of their chance because of lack of security. The necessary corollary of the Minister's stand on the basic salary was that the State should make provision for the best students not only to qualify as doctors but also to have the opportunity of doing postgraduate work and research. He was convinced that in years to come the medical profession would see that it was in their own interests that part of their remuneration should be by basic salary. The amendment was negatived by 303 votes to 128.

The reasons for disagreeing with certain of the Lords' amendments were reported, and it was agreed to communicate them to the Upper House.

FROM THE PRESS GALLERY

Christian Science Nurses

On Oct. 29 in the House of Lords Viscount **Astor** moved to annul the Nurses Amendment Regulation made under the Nurses Act, 1943. A similar motion brought forward by Mr. Alfred Edwards was negatived in the Commons on Oct. 14.[1] Christian Science nurses, Lord Astor explained, were not taught the medical side of nursing, but in general hygiene their training was not dissimilar. Christian Science treatment, he continued, was not illegal; it was recognised by the Public Health Act, 1936. If this regulation was not repealed we should have a law which would be difficult to enforce and which would savour of persecution and intolerance. Were these women to be fined or imprisoned because they used the title laid down in the constitution of their Church? The Christian Scientists, Lord Astor was authorised to say, would not object to any regulation making it illegal for Christian Science nurses to advertise by name-plate, in the Press, or in any general publication. But they asked that they should be permitted to use the Christian Science Nurses in their official publications in the records of their Church.

Lord **Horder** declared this was a matter of p polity. For some time an effort had been made, unsuccessfully, to raise the status of nurses. There now statutory recognition of two types of nurse—"assistant nurse" and the State-registered nurse. T were being asked to recognise another category they were assured would only advertise itself the medium of particular journals. *If they could* an assurance—Lord Horder did not think they that those journals were confined to this pa religious body, there might perhaps be some with Lord Astor's motion. But it was common knowl that the circulation of at least one of those C Science journals was large and universal, and on th ground Lord Horder did not think the safeguard for t nursing profession was adequate. Therefore he hop that the motion would not receive their Lordshi support.

Lord **Llewellin** doubted whether it would be possi to bring home to any British subject who was describ as a Christian Science nurse in a paper published abro that an offence under the Act had been committed.

Viscount **Addison** pointed out that Noble Lor must either approve or disapprove of regulations. Th could not amend them. As to Lord Astor's comprom it did not come into the matter, for we could not contr what was printed in the newspapers of the United States. This was not a religious controversy, he continued. What mattered was to safeguard the interests of the nursing profession. In the view of the Government it was not right that any set of people who were not nurses, whatever their religious convictions, should describe themselves as nurses. People did not refer to Christian Science doctors or Methodist doctors. Doctors had a medical qualification and that was the test of their being entered on the Medical Register, and the same applied to nurses. The motion to annul the regulation was negatived by 55 votes to 11.

Dental Controversy

In the House of Commons on Oct. 25 Mr. **John Baird**, L.D.S., pointed out that dental benefits for insured people were different from medical benefits because the latter were compulsory while the former were paid only by those insurance societies which had surplus profits, and this inadequate method had always been accepted reluctantly by the dentists. During the war the Dental Benefit Council, which had on the whole functioned well, was in abeyance, and negotiations between the profession and the Ministry were carried on by an emergency committee. In 1944 a new scale of fees was agreed on, again reluctantly, by the dentists, and in 1945 uneasiness arose among them and unfortunately, in the South of England especially, many withheld their services from National Health Insurance. As a result, negotiations took place between the Ministry of Health, who were then responsible, and the leaders of the dental profession. The strike was called off and the Minister gave an undertaking that he would reconstitute the Dental Benefit Council and set up the Spens Committee to inquire into their future remuneration.

The present point at issue, Mr. Baird declared, was not chiefly the scale of fees but the method of negotiation between the profession and the Government. A long-established machinery was being turned down, and the Minister was imposing on the profession, without consultation, a scale of fees which was considerably lower than that suggested by the Dental Benefit Council. The Spens Committee could not report before the summer, and if this dispute was allowed to continue until then a running sore would be created which would be difficult to remove. The Government ought to establish negotiating machinery in which both sides could have confidence. Mr. Baird agreed that the aim should be to encourage people to conserve their teeth rather than have them extracted and replaced by dentures, but many people had neglected their teeth, so that extraction and the fitting of dentures would continue for some years, and it was now impossible for a dentist to get a reasonable margin of profit for dentures provided under National

[1] *Lancet*, Oct. 26, p. 621.

Shorncliffe Area, but in 1939 he was transferred, with the rank of major, to a Territorial Army hospital which had been formed in Birmingham. He was mobilised in August, 1939, and served as a pathologist in England, France, and India until August, 1943, when he became principal histopathologist to the new central laboratory for India Command, at Poona. In September, 1944, he was promoted to lieut.-colonel on appointment as assistant director of pathology (research) at General Headquarters, India Command, Delhi. In this post he was responsible not only for the initiation and administration of research in clinical pathology throughout India Command; under his charge eight research teams investigated problems concerned with scrub-typhus, amœbic dysentery and other protozoal diseases. penicillin and mepacrine therapy, and other subjects.

In October, 1945, he was inducted into the chair of pathology at St. Andrews University; but a few weeks later he fell ill and was ordered a long rest. Latterly his condition seemed to improve, and there was some prospect of his returning to duty.

Stuart McDonald was an outstanding teacher, with an unusual flair for stimulating the enthusiasm of his students, in whom he took a personal interest, sparing no effort to help them in their difficulties. His published papers and the many communications he made to scientific societies indicated his powers of exposition, and proved him to be a skilled and accurate observer, scrupulously attentive to detail and possessing a wide knowledge of his subject. He applied sound judgment to the interpretation of difficult cases, and his hospital work was much appreciated by his clinical colleagues. He was an enthusiastic angler and shot: he was, too, a good mixer, liked and respected by all who knew him. His sudden and unexpected death came as a great shock to his many friends.

He leaves a widow and two daughters.

SIDNEY DEANER

M.R.C.S.

Dr. Deaner, chief tuberculosis officer for Worcestershire, who died on Oct. 15 at the age of forty-two, qualified at St. Mary's Hospital in 1927. After a few valuable months spent in general practice he held house-appointments at the King Edward Memorial Hospital, Ealing, where he became interested in tuberculosis. He acquired further clinical and administrative experience at the South Wales Sanatorium, at Papworth, and in the Sheffield health department.

In 1932 he went to Worcestershire when the chief tuberculosis officer was Dr. Gordon Smith. Deaner gained his complete confidence and proved the ideal tuberculosis officer—enthusiastic, willing, and sympathetic, with never-failing courtesy, proud to be at the service of the patients and doctors of the county. When Gordon Smith died in 1939 there was no doubt who his successor should be, and Deaner was appointed to the position, which he held until his death. He loved hard work and had the organising ability and imagination necessary for progress; and it was on his advice that the council provided a unit for chest surgery at Knightwick Sanatorium, under the charge of Mr. Holmes Sellors. His popularity as a consultant was understandable. for he displayed the abilities of a general physician as well as those of a specialist in tuberculosis. At the beginning of the war Deaner and the other two county tuberculosis officers all wished to join the Services, but Deaner could not be spared. At once he started to train the central clerical staff in first-aid work, and later as detraining officer at the Worcester railhead he directed a devoted and efficient band of stretcher-bearers who dealt with convoys of Service patients. He took a leading part in reviving the Midland tuberculosis group of the Society of Medical Officers of Health, and became its secretary. He was also secretary of the Worcester and Bromsgrove division of the B.M.A. Three years ago the first symptoms of a fatal disease appeared. but his courage and the love of his work never left him. and in his last months he struggled with Russian grammar in the hopes of becoming a translator of medical books.

"Sidney Deaner," writes a colleague, "was the perfect T.O. He knew the tuberculous families, their homes, their work, and their difficulties; he helped their future. Much of his time was spent in the pensaries, slums, and factories of the Black C Industrial diseases interested him immensely and described silicosis amongst the Stourbridge claym Robust, energetic, and stocky, with a straight back, black curly hair, one recalls him on the terrace Knightwick Sanatorium on the Ankerdine hillside a bundle of tomograms selected for the next of the clinical society. Here, overlooking his fa Teme Valley, he delighted to be, and he was certain have plenty of interesting cases to show to the d sought his help. Happy are the memories he has in Worcestershire."

He leaves a widow and a young son.

Diary of the Week

NOV. 10 TO 16

Monday, 11th

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1
8.30 P.M. Dr. E. R. A. Merewether: Field of Research in Indust Health.

Tuesday, 12th

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
5.30 P.M. *Psychiatry.* Dr. H. Eysenck: Measurement Personality.

CHELSEA CLINICAL SOCIETY
6.30 P.M. (South Kensington Hotel, 41, Queen's Gate Terra S.W.7.) Mr. B. H. Burns, Mr. Charles Read, Dr. Bewley: Backache.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.2
5 P.M. Dr. H. Corsi: Diseases of the Nails.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE
5 P.M. (Royal Infirmary.) Mr. Angus Sinclair: Interdepend of Biology and Other Branches of the Higher Learnin

Wednesday, 13th

ROYAL SOCIETY OF MEDICINE
4.30 P.M. *Physical Medicine.* Sir Max Page: Uses of Ph therapy in an Accident Service.

MEDICAL SOCIETY OF THE L.C.C. SERVICE
4.30 P.M. (County Hall, Westminster Bridge, S.E.1.) Dr. Alston, Dr. B. Young, Mr. M. Jemson: Penicillin Treatment of Disease.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Por Place, W.1
3.30 P.M. Miss Barbara M. Duncum, D.PH.: Popular Hist Anæsthesia.

Thursday, 14th

UNIVERSITY OF LONDON
5 P.M. (University College, Gower Street, W.C.1.) Sir J Barcroft, F.R.S.: Recent Work on Placental Transm

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn F W.C.2
5 P.M. Sir Heneage Ogilvie: Surgical Handicraft. (Brad lecture.)

ROYAL SOCIETY OF MEDICINE
5 P.M. *Ophthalmology.* Dr. Godtfredsen (Denmark), Mr. E. Davis: Eye Signs in Malignant Nasopharyngeal Tum Mr. F. W. Law: Ring Scotoma after Retrobulbar Ne Cases will be shown.

PROVISIONAL NATIONAL COUNCIL FOR MENTAL HEALTH
10.30 A.M. (Caxton Hall, Westminster, S.W.1.) Conferen Mental Health: opening session. Dr. J. R. Rees: Ap tion to the Civilian Population of War-time Exper of Neurosis and Backwardness in the Forces. Dr. Main: Employment of the Mentally and Emotio Handicapped.

SOCIALIST MEDICAL ASSOCIATION
7.30 P.M. (296, Vauxhall Bridge Road, S.W.1.) Dr. F. R. G. H Social Aspects of Tuberculosis.

LONDON SCHOOL OF DERMATOLOGY
5 P.M. Dr. Sydney Thomson: Animal Diseases Communic to Man.

Friday, 15th

ROYAL COLLEGE OF OBSTETRICIANS AND GYNÆCOLOGISTS, 58, C Anne Street, W.1
5 P.M. Dr. J. M. H Campbell: Heart in Pregnancy.

ROYAL SOCIETY OF MEDICINE
8 P.M. *Obstetrics and Gynæcology.* Mr. Everard Williams Terence Millin: Stress Incontinence in Micturition.
8 P.M. *Radiology.* Miss M. S. Cripps, Miss Baker, Dr Fr Dr. N. S. Finzi: X-ray Treatment of Inflamm Diseases.

FACULTY OF RADIOLOGISTS
2.30 P.M. (Royal College of Surgeons.) Sir Gordon Gordon-Ta Malignant Tumours of the Testicle. (Skinner lecture.)

TUBERCULOSIS ASSOCIATION
3.15 P.M. (26, Portland Place, W.1.) Dr. J. F. Brailsford: T nique and Standardisation of Radiographs of the Cl
5.15 P.M. Dr. G. S. Todd, Dr. David Anderson: Chest Diseases Flying.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY
8 P.M. (West London Hospital.) Clinico-pathological meetin

LONDON CHEST HOSPITAL, Victoria Park, E.2
5 P.M. Dr. Shirley Smith: Heart in Pulmonary Disease.

OBSERVATIONS ON THE SYCHOLOGY OF THE TUBERCULOUS*

GEORGE DAY
M.A., M.D. Camb.
RESIDENT PHYSICIAN, MUNDESLEY SANATORIUM, NORFOLK;
LATE CAPTAIN R.A.M.C.

THE material for this study is drawn from a rather ecialised class of tuberculous patient. These patients, r their relations, are in a position to afford substantial es for their sanatorium treatment. This buys them etailed and unhurried medical attention as well as rather xurious amenities which they would not enjoy in less expensive establishment. This specialised class oes not, however, consist of the Idle Rich. The Idle Rich either does not get tuberculosis, or, if it does, takes t to Switzerland or the South of France. Our patients re mostly hard-working professional men and women, nd are drawn from the Army, the Navy, the Church, nd the Stage—barristers, doctors, schoolmasters, bookmakers, business men, and their wives, sons, and aughters.

It is a special group in that the patients have not been subjected to the stresses and strains classically held to be responsible for pulmonary tuberculosis—malnutrition, overcrowding, bad working conditions, or exposure. By this standard there appears to be no excuse for their breakdown. Then why do they break down? Obviously because they have become infected by the tubercle bacillus (as we all do); but for some reasons their tissues are in a condition to give it a good home instead of destroying it or imprisoning it for life. Is it just by chance that their tissues are so hospitable?

In 1935 I noticed a striking thing. So often there emerged from the patient's recent history an unhappy love episode. Girls had been jilted, young men had got themselves engaged to the utterly wrong girl, and were in painful conflict realising it more or less consciously. This state of affairs seemed to be far commoner than chance would warrant. It looked as if the Victorian novelists had got hold of a little-understood truth when they portrayed their lovelorn heroines going into a decline.

Another puzzling aspect was that tuberculosis struck down young adults. Why? The physical body should surely then be at its prime. It is fully grown: metabolism is no longer concerned partially with growth and development but wholly with repair and replacement. Could the answer be that young adulthood is a time when emotional stresses reach their highest peak? In the group I am discussing it is a time for weaning from the family circle and the backing and security of the home. The men in particular have to stand on their own feet and accept the consequences of their choice, be it of helpmeet or lifework. It is a time of hopefulness, too much hopefulness perhaps; but it is a worrying time, indeed a frightening and suicidal time for some.

As time went on I found I could extract relevant facts from an increasing proportion of patients—it increased from about 5% to nearly 50% as my shyness wore off and as I came to use dream analysis. And in 60% of these cases I could discern a very good reason why tuberculosis or some similar chronic incapacitation was *necessary* to them at that juncture. I could also see why it would continue to be necessary to them, unless something in their life-pattern suffered change. But it was disappointingly seldom that I was able to do anything to bring the change about.

So in 30% of the whole sanatorium population, I decided, the patient was sick in mind as well as body.

CASE OF THE YOUNG DOCTOR

My first case is that of a young Irish doctor who developed pulmonary tuberculosis while doing a house-physician's job in the south of England.

Alan was a popular stocky little fellow—the bustling rugger-forward type—full of vitality, who rapidly became persona grata with everyone in the sanatorium. His lesions, however, failed to respond to treatment, and he was still on bed rest at the end of six months. An artificial pneumothorax was attempted, but it did not relax the cavity-containing zone, because there was an intractable adhesion holding it out. He had a three-month course of 'Sanocrysin' injections without converting his sputum even temporarily. At the end of six months his general condition was good; he had gained lots of body-weight and looked and felt fighting fit, but his rectal temperature rose to 37·6° C (99·7° F) each evening; his sputum, though scanty, was still positive; his blood-sedimentation rate remained steadily higher than it should have been. His disease activity was in statu quo.

Then we crushed his phrenic nerve. It worked like a charm. His diaphragm rose and within a few days his temperature had dropped to normal limits. His B.S.R. dropped steadily and he became sputum-free. And then he awoke one morning with glove-and-stocking anæsthesia. Being a doctor he had diagnosed it himself before we could answer his bell, and we found him bellowing, "Why the hell have I got a conversion hysteria?" It was no good asking *us*. *We* didn't know. He started sweating almost continuously; he couldn't sleep; and by the end of the week he had shrunk a stone in weight.

Then one evening in a darkened room he told his story. He was a Roman Catholic, and his fiancée, who was an extremely nice girl, was also a Roman Catholic. But he was possessed, as it were, of two personalities, a saint who was a devout practising Roman Catholic and a sinner who wasn't; and they were not on speaking terms. The saint adored his beloved with religious fervour, but the sinner treated her differently. His fiancée was devoted to him, but was shamed at being forced to enjoy prenuptial bliss against her better inclinations. So their relationship became degraded in both their eyes, and they were pretty miserable though deeply in love with each other. I think it is significant that he took a house-job in the south of England—just about as far from Ireland as he could get.

Here he became involved with a nurse, developed the signs and symptoms of tuberculosis (with, he confessed, no little feeling of relief), and sped back to Ireland to his mother and his fiancée. He was not too easy there, and he again elected to cross large tracts of land and water to Mundesley, where he was happy, carefree, and well esteemed by his fellows. And now, when he showed *signs* of getting better of his tuberculosis, he himself gets very sick in spirit. It seemed obvious that he was not yet ready to re-enter the world from which tuberculosis had afforded him escape.

What seemed so odd to me was that he had never grouped all these phenomena in his own mind before; but then I suppose people don't. He *did* see it when it was pointed out to him, and he *did* see that the saint in him and the sinner in him had to be reconciled and come to terms and be atoned, if he wanted to become an integrated human being.

The next thing that happened was that he sent for his fiancée, confessed all, and was forgiven. He made a rapid and uninterrupted progress from then onwards.

Two years later I ran into him again, and he was simply crackling with good health. But I noticed he did not introduce me to the girl he had with him. I couldn't help wondering whether the saint hadn't mixed a little too freely with the sinner, and ended up like the young lady from Riga.

FANTASIA

From a particular and completely unvarnished case-history I wish to turn to a blended version of several cases which had sufficient points in common for this

---

* A paper read to the Northfield Psychiatric Society, Northfield Military Hospital, Birmingham, in November, 1944.

Association of Plastic Surgeons

The meeting to inaugurate this association, at the Royal College of Surgeons on Wednesday, Nov. 20, at 5 P.M., will be followed by a dinner at the college. Those wishing to attend the dinner should notify the secretary, Sir Harold Gillies, 149, Harley Street, London, W.1.

Genetical Society

A public lecture will be delivered at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, at 5 P.M., on Friday, Nov. 22, by Prof. Tage Kemp, director of the University Institute of Human Heredity, Copenhagen, who will speak on *Multiple Factors in Morbid Inheritance*; a film, *the Fat Dwarf*, will be shown.

Socialist Medical Association

The following lectures will be given at 296, Vauxhall Bridge Road, S.W.1, on Thursdays, at 7.30 P.M.: Nov. 14, Dr. F. R. G. Heaf, Social Aspects of Tuberculosis; Nov. 28, Dr. F. Avery Jones, Social Aspects of Peptic Ulcer; Dec. 12, Dr. J. Tylor Fox, Social Aspects of Epilepsy; Jan. 2, Dr. A. T. M. Wilson, Social Aspects of Medical Psychology; Jan. 16, Dr. J. N. Morris, Social Aspects of Juvenile Rheumatism; and Jan. 30, Dr. H. Joules, Occupational Hazards of the Health Worker.

Association of Anæsthetists

On Oct. 31 the Association of Anæsthetists of Great Britain and Ireland celebrated the centenary of anæsthesia by holding a dinner in the great hall of Lincoln's Inn. Sir Alfred Webb-Johnson, P.R.C.S., said that the achievements of British medicine in the past hundred years made up one of the brightest constellations in the history of this country. The early work on anæsthesia formed a sort of prologue to the development of antisepsis, X rays, radium, bacteriology, vitamins, and hormones. Anæsthetists might well feel what Oliver Wendell Holmes called "a noble satisfaction" in steering their patients through some of the most critical situations of life. They were right to insist on their status, which was that of a practical practising physician, administering drugs of great potency, and assessing the fitness of patients to receive them. They were also practical common-sense people who had established their headquarters in Lincoln's Inn Fields. Dr. A. D. Marston, the president, said that anæsthetists had much to gain from other specialties and from combined operations against disease. But they also had their autonomous moments and were expanding their sphere, and he was glad to see that Birmingham had led the way by putting an anæsthetist in charge of resuscitation and the treatment of shock. Not so long ago the British Medical Association held that every general practitioner's knapsack held a bottle of chloroform which might be used at any time for any operation; but the B.M.A. now recognised the value of the specialist anæsthetist and had acceded to a request from 400 members to form an anæsthetists' group. Replying to Dr. John Gillies's toast of The Guests, Dr. Charles Hill, secretary of the B.M.A., feared lest the bottle of chloroform in the practitioner's knapsack might be replaced by a mass of printed forms to be completed in triplicate. Commenting on reports of a recent speech by Mr. Bevan to medical students, he concluded a topical rejoinder by remarking that the Minister needed no guidance in using the chloroform which comforts, the ether which irritates, or the curare which induces muscular relaxation. Dr. Wesley Bourne, of Montreal, bringing greetings from Canada and the United States, pointed out that, in commemorating the early anæsthetists, we should properly go back to the philosophers of chemistry—Priestley, Davy, Lavoisier, Faraday—by whom man has ever since been kept on tiptoe. He quoted Paget's saying that the fault in specialisation lies not in narrowness but in shallowness and a sense of self-sufficiency. Dr. Murchi, of Copenhagen, also responded as a guest. Finally, Dr. Z. Mennell said that, as every anæsthetist knows, what counts is the man behind the machine; and the president's health was drunk with musical honours.

Corrigenda.—In our annotation on Training in Child Welfare (*Lancet*, Oct. 26, p. 608) we stated that the National Nursery Certificate is planned for girls between 14 and 16 years of age. Actually it is planned for girls between 15 and 17, and the age is to be raised to 16–18 as soon as possible.

An annotation last week on Cancer of the Corpus Uteri quoted Professor Heyman as saying that in reported series of cases treated by hysterectomy he had found a relative five-year survival-rate of 40–50%. The percentage should have been stated as 48–55.

Appointments

BECK, A., M.D. Frankfurt, L.R.C.P.E.: pathologist, North-
Hospital, Hampstead.

BOWYER, H. W., M.D. Glasg.: assistant physician to outp
Bolton Royal Infirmary.

HERVEY, W. A., F.R.C.S.E.: otorhinolaryngologist, Queen
Hospital for the East End, London.

London Hospital, Whitechapel:

BOWEN-DAVIES, A., M.B. Camb., F.R.C.S.: assistant sur
aural department.

PERRY, K. M. A., M.D. Camb., M.R.C.P.: assistant physic

THOMPSON, V. C., M.B. Lond., F.R.C.S.: assistant sur
thoracic department.

VAUGHAN-JACKSON, O. J., B.M. Oxfd, F.R.C.S.: assistant
to orthopædic and accident department.

Hampstead General and North-West London Hospital:

ENZER, J., M.R.C.S.: physiotherapist.

HINDENACH, J. C. R., M.D. N.Z., F.R.C.S.: orthopædic and
surgeon.

Middlesex County Council:

Births, Marriages, and Deaths

BIRTHS

JAMIESON.—On Oct. 24, at Edinburgh, the wife of Dr. J
Jamieson—a daughter.

MCDOWALL.—On Oct. 30, at Emsworth, Hants, the wife
E. B. McDowall—a daughter.

PRICE.—On Oct. 30, at Oxford, to Dr. Celia Westropp, the
Mr. Francis Price—a son.

STRONG.—On Oct. 27, at Liverpool, the wife of Dr. John S
a daughter.

STUART-HARRIS.—On Nov. 2, at Sheffield, the wife of Prof
Stuart-Harris, F.R.C.P.—a daughter.

THOMPSON.—On Oct. 25, at Horsham, the wife of Dr. F. A.
son—a son.

MARRIAGES

BROOKS—BLAGG.—On Oct. 31, at Car-Colston, Notts, Ge
Brooks, G.M., M.C., M.B., to Ursula Grace Blagg.

GRIFFIN—JORGENSEN.—On Oct. 26, at Chislehurst, Ge
Griffin, M.R.C.S., to Thelma Doreen Jorgensen.

DEATHS

BARNETT.—At Dunedin, New Zealand, Sir Louis Edward
C.M.G., M.D. Edin., F.R.C.S., emeritus professor of surge
University of Otago, aged 81.

CROFT.—On Oct. 31, at Nuneaton, John Thomas Herber
M.R.C.S.

HALSTED.—On Oct. 29, at Selsey, Sussex, Harold Cecil
M.D. Durh., aged 81.

HIRD.—On Oct. 30, at Wimbledon, Frederick Robert Hird,

MCKENDRICK.—On Oct. 31, at Glasgow, John Souttar McKe
M.D. Glasg., F.R.F.P.S., F.R.S.E., aged 72.

MILLIGAN.—On Oct. 30, at Bournemouth, James Milliga
Durh., L.D.S. R.C.S.

THORNTON.—On Oct. 26, at Pretoria, Brigadier Sir Edward N
Thornton, K.B.E., V.D., M.R.C.S., D.P.H.

VAKIL.—On Oct. 23, in London, Chunilal Bhimbhai Vakil,
aged 63.

OBSERVATIONS ON THE SYCHOLOGY OF THE TUBERCULOUS*

GEORGE DAY
M.A., M.D. Camb.
RESIDENT PHYSICIAN, MUNDESLEY SANATORIUM, NORFOLK;
LATE CAPTAIN R.A.M.C.

THE material for this study is drawn from a rather pecialised class of tuberculous patient. These patients, r their relations, are in a position to afford substantial es for their sanatorium treatment. This buys them etailed and unhurried medical attention as well as rather xurious amenities which they would not enjoy in less expensive establishment. This specialised class loes not, however, consist of the Idle Rich. The Idle Rich either does not get tuberculosis, or, if it does, takes t to Switzerland or the South of France. Our patients re mostly hard-working professional men and women, nd are drawn from the Army, the Navy, the Church, nd the Stage—barristers, doctors, schoolmasters, bookmakers, business men, and their wives, sons, and daughters.

It is a special group in that the patients have not been subjected to the stresses and strains classically held to be responsible for pulmonary tuberculosis—malnutrition, overcrowding, bad working conditions, or exposure. By this standard there appears to be no excuse for their breakdown. Then why do they break down? Obviously because they have become infected by the tubercle bacillus (as we all do); but for some reasons their tissues are in a condition to give it a good home instead of destroying it or imprisoning it for life. Is it just by chance that their tissues are so hospitable?

In 1935 I noticed a striking thing. So often there emerged from the patient's recent history an unhappy love episode. Girls had been jilted, young men had got themselves engaged to the utterly wrong girl, and were in painful conflict realising it more or less consciously. This state of affairs seemed to be far commoner than chance would warrant. It looked as if the Victorian novelists had got hold of a little-understood truth when they portrayed their lovelorn heroines going into a decline.

Another puzzling aspect was that tuberculosis struck down young adults. Why? The physical body should surely then be at its prime. It is fully grown: metabolism is no longer concerned partially with growth and development but wholly with repair and replacement. Could the answer be that young adulthood is a time when emotional stresses reach their highest peak? In the group I am discussing it is a time for weaning from the family circle and the backing and security of the home. The men in particular have to stand on their own feet and accept the consequences of their choice, be it of helpmeet or lifework. It is a time of hopefulness, too much hopefulness perhaps; but it is a worrying time, indeed a frightening and suicidal time for some.

As time went on I found I could extract relevant facts from an increasing proportion of patients—it increased from about 5% to nearly 50% as my shyness wore off and as I came to use dream analysis. And in 60% of these cases I could discern a very good reason why tuberculosis or some similar chronic incapacitation was *necessary* to them at that juncture. I could also see why it would continue to be necessary to them, unless something in their life-pattern suffered change. But it was disappointingly seldom that I was able to do anything to bring the change about.

So in 30% of the whole sanatorium population, I decided, the patient was sick in mind as well as body.

CASE OF THE YOUNG DOCTOR

My first case is that of a young Irish doctor who developed pulmonary tuberculosis while doing a house-physician's job in the south of England.

Alan was a popular stocky little fellow—the bustling rugger-forward type—full of vitality, who rapidly became persona grata with everyone in the sanatorium. His lesions, however, failed to respond to treatment, and he was still on bed rest at the end of six months. An artificial pneumothorax was attempted, but it did not relax the cavity-containing zone, because there was an intractable adhesion holding it out. He had a three-month course of 'Sanocrysin' injections without converting his sputum even temporarily. At the end of six months his general condition was good; he had gained lots of body-weight and looked and felt fighting fit, but his rectal temperature rose to 37·6° C (99·7° F) each evening; his sputum, though scanty, was still positive; his blood-sedimentation rate remained steadily higher than it should have been. His disease activity was in statu quo.

Then we crushed his phrenic nerve. It worked like a charm. His diaphragm rose and within a few days his temperature had dropped to normal limits. His B.S.R. dropped steadily and he became sputum-free. And then he awoke one morning with glove-and-stocking anæsthesia. Being a doctor he had diagnosed it himself before we could answer his bell, and we found him bellowing, "Why the hell have I got a conversion hysteria?" It was no good asking *us*. *We* didn't know. He started sweating almost continuously; he couldn't sleep; and by the end of the week he had shrunk a stone in weight.

Then one evening in a darkened room he told his story. He was a Roman Catholic, and his fiancée, who was an extremely nice girl, was also a Roman Catholic. But he was possessed, as it were, of two personalities, a saint who was a devout practising Roman Catholic and a sinner who wasn't; and they were not on speaking terms. The saint adored his beloved with religious fervour, but the sinner treated her differently. His fiancée was devoted to him, but was shamed at being forced to enjoy prenuptial bliss against her better inclinations. So their relationship became degraded in both their eyes, and they were pretty miserable though deeply in love with each other. I think it is significant that he took a house-job in the south of England—just about as far from Ireland as he could get.

Here he became involved with a nurse, developed the signs and symptoms of tuberculosis (with, he confessed, no little feeling of relief), and sped back to Ireland to his mother and his fiancée. He was not too easy there, and he again elected to cross large tracts of land and water to Mundesley, where he was happy, carefree, and well esteemed by his fellows. And now, when he showed signs of getting better of his tuberculosis, he himself gets very sick in spirit. It seemed obvious that he was not yet ready to re-enter the world from which tuberculosis had afforded him escape.

What seemed so odd to me was that he had never grouped all these phenomena in his own mind before; but then I suppose people don't. He *did* see it when it was pointed out to him, and he *did* see that the saint in him and the sinner in him had to be reconciled and come to terms and be atoned, if he wanted to become an integrated human being.

The next thing that happened was that he sent for his fiancée, confessed all, and was forgiven. He made a rapid and uninterrupted progress from then onwards.

Two years later I ran into him again, and he was simply crackling with good health. But I noticed he did not introduce me to the girl he had with him. I couldn't help wondering whether the saint hadn't mixed a little too freely with the sinner, and ended up like the young lady from Riga.

FANTASIA

From a particular and completely unvarnished case-history I wish to turn to a blended version of several cases which had sufficient points in common for this operation. Here is an extract from an article I published pseudonymously just before the war[1]:

---

* A paper read to the Northfield Psychiatric Society, Northfield Military Hospital, Birmingham, in November, 1944.

> "The most hopeless case is the one who exhibits what I call the 'Dornford Yates syndrome.' She (and it's nearly always a she) really believes that somewhere round the corner there exists such a world as that gifted writer portrays in his delirious fantasies: a world where women are worshipped from the crowns of their heads to their glittering insteps by clean-limbed leisured sportsmen with a taste for witty philandering; where every lawn is centuries old and every car a Rolls. It is a make-believe world we create whenever we put on evening dress and smoke cigars and behave a little above ourselves; but most of us accept the twopenny bus-ride back to reality with something like relief.
>
> "The 'D.Y.S.' not only believes it exists, but that it is her rightful kingdom from which she is exiled for having been born to the wrong parents or having married the wrong husband. Cinderella's Prince Charming does not live up to premarital sample. Disabling illness of any kind provides an escape from reality into a world which matches her fantasy. On her admission to a nursing-home or sanatorium she enters her kingdom—or should I say queendom? Enthroned in bed she gains the power and the glory about which hitherto she has only been able to dream. Meticulous service she exacts from all who attend her, rewarding here with a gracious word, reproving there with queenly displeasure. Visitors, inquiries, gifts of flowers, and exciting negligées all heighten the illusion. Her rapid unpopularity among the other patients is, of course, rationalised. 'The other patients dislike me, my dear, simply because the doctors make rather a favourite of me,' confided a Queen Me to a newcomer (who went to the trouble of ascertaining if it were true!)—'I have never been so neglected in my life,' she once snapped at a goggling floor-maid, and added, skilfully avoiding understatement, 'but then at home I had seven servants.'—'Really, mum, would that be all together or one after another?' innocently asked the floor-maid; and was reported for impertinence.
>
> "Reality has an uncomfortable way of breaking through the best fantasies, and, when it does, the time has come to move to another establishment, bearing horrific tales of the short-comings of the last one which forced the patient to abdicate.
>
> "Now, the striking feature about cases of this kind is not that the disease runs a sluggish and protracted course, but that all attempts at adjuvant treatment seem doomed to meet with failure. Artificial pneumothoraces prove unselective; section of adhesions fails to close cavities; sanocrysin therapy provokes forbidding constitutional reactions. A malign Fate seems at work. A dramatic improvement once occurred when a husband's interest was found to be straying elsewhere.... But it might equally well have caused a dramatic decline, so it is not to be advocated. She is, after all, the victim of a disorder more intractable even than her tuberculosis, which is in comparison only a stage-property. She is perfectly adjusted to Being an Invalid, so why should she get well?"

PSYCHOLOGICAL ASSISTANCE

In general practice, having decided that an illness is functional and psychopathological in origin, one is faced with the problem—what is to be done about it? It is profoundly difficult to bring home to a patient one's conviction that he has within him a "black spot, not so big as a pin's head, but waiting to spread and destroy him in the fullness of time"—when the black spot is neither cancer nor tubercle but—Fear. Unless seriously distressed, patients in private practice are apt to take umbrage at the mere suggestion that they should undergo any systematic psychological treatment. It is an aspersion on their sanity. But delicate, difficult, and disagreeable as the task may prove, such a patient must have it brought home to him that he is sick at heart as well as in body, and that he can be helped to help himself. Before anything can be attempted he must become aware of a need for help and feel a genuine desire for it. Only then will he cooperate without doubts and misgivings.

Personally, I have found that dream analysis meets most situations, if you have the time; and in sanatorium practice you have plenty of time. It starts off like a new game, but soon becomes more and more eng and deeper and deeper in its effect, and eventually patient gets the knack of analysing his own dreams the minimum of guidance. In fact he does all the When he gets tied up he asks for guidance, and in happy experience at this stage your presence is purely catalytic. It doesn't matter what you say suggest. If your suggestion misses the mark, it bou off and is ignored. You have done no harm. But if hit the gold, it "brings him up all standing and car away his bob-stay"; or perhaps, better still, your sug tion is angrily repudiated, resisted, and rejected. you have sown the seed, and it is only a matter of t before it flowers. Quite often a misunderstanding ring the bell:

> A discontented ex-patient, who was living alone lodgings in the village (rather than go home to her mot putting off the evil day), used to come up to see twice a week. Her mother was her chief immediate prob The mother was a deaf and dowdy earnest woman rather disliked her darling daughter but did not know The darling daughter detested her mother, knew it, gloried in it.
>
> One day the girl was pouring out a long dream with her o running commentary, but my mind was elsewhere. The vill amateur dramatic society, I knew, was about to start wor just the thing for her! Give her a chance to meet some peo purposefully and not merely socially. She'd be able to g herself a much-needed rest for two or three evenings a we Impulsively I blurted out, "Are you interested in amat theatricals?" "I *loathe* amateur theatricals," she repli "Why?" "All right, all right. Don't snap my head Nothing, nothing. Go on. I'm listening."
>
> The next time she came to see me she said, "Sorry I so dense. The penny didn't drop until next day. I know why you asked me about amateur acting, you pig. It's p fectly true; I *am* dramatising myself the whole time. I ne realised it before. What can I do about it? I find I'm doi it the whole time, blast you." For the first time she completely natural.

And that is the way of it. Very often one's mo cryptic utterances, which one could not explain or defe if challenged, may bear fruit. For whoever carries question to the oracle on his lips also carries the answ in his heart. Shakespeare came very near it when said:

> "Our remedies oft in ourselves do lie
> Which we ascribe to Heaven."

He might have added "or to the doctor."

In my next case I used dream analysis and unearth material I could not possibly have got any other wa for the patient was intelligent and intellectual and h an almost maddening amount of poise.

> She had read more Freud than I had, and thought th was a tremendous lot in it—applied to other people. By standards she judged herself to be pretty well all right. T patient was a doctor's wife and therefore had not been di nosed until both her lungs had become pretty extensive excavated. She was treated with bilateral A.P.s, adhesio were cauterised on both sides, and from the viewpoint pure lung-carpentry we achieved what we wanted. But s did not heal. She hung fire.
>
> Her dreams showed clearly that her marriage was a failu —more, that it was in effect her wasting disease of which tuberculosis was a somatic expression. She had never admitt that she was ill-mated, even to herself. Her husband, w had a touch of the Asiatic in his blood, was an expert a experienced love-maker. One moment he fascinated and ter fied her by his ruthlessness, and the next could put on a "hurt small boy" act which never failed to arouse her motherly feelings. At every turn she was completely in his power and completely frustrated from being herself when he was about.
>
> One dream I would like to relate without comment. She was fishing in clear deep water from the lower steps of a jetty, when suddenly a sort of Loch Ness monster reared its ugly head and rushed across the bay straight at her. She turned,

---

[1] *Lancet*, 1939, i, 1343.

reaming in terror, and fled up the steps to me, who was tanding at the top, and awoke.

Eventually she decided to divorce her husband for cruelty, oth mental and physical, for which she had a very good case, nd her papers were sent in. Her tuberculosis which had hung re all these months began to get better.

The case was defended and lasted three days. She had a ruelling time in the box, for her ruthless husband had left o sofa-cushion unturned in his search for letters of one sort r another with which to bolster up his counter-evidence. he came through well and won hands down.

After the decree nisi she was forced to have embarrassing ealings with her ex-husband concerning the welfare of heir joint children, and her emotions towards him were ather confused. He was so charming, courteous, and onsiderate.

She continued to send me her dreams with her own interretations for my comments. And this is the last one she ent me. She was fishing in deep clear water from the lower teps of a jetty, as in the other dream, but on the other side, acing east instead of west. Suddenly a sort of Loch Ness monster reared its ugly head and rushed across the bay at her. She turned, screaming in terror, and was about to flee up the teps, when she heard me chuckling with amusement. So she tood her ground and seized the monster in both hands. It shrank and shrank until it was a poor little iridescent minnow in the palm of one hand. She gently threw it back into the water.

(I will comment on this second dream. I think it pretty decent of her unconscious to drop us a line to let us know how we are getting on.)

She married again, this time a man more her own weight, somebody who laughs at the same thing as she does, and her tuberculosis is arrested.

HAPPINESS IS NOT ENOUGH

To me, concerned with getting people to overcome their tuberculosis by fair means or foul, that case strengthens my belief that a change of heart and a change of circumstances can be necessary before healing will proceed. My next one shows how change of circumstances alone. . . .

Peggy had an unfortunate early history. She never knew her father, her mother died when she was fourteen, and from then onwards she was self-supporting. She was in turn parlourmaid, cook, chorus girl, shop girl, mannequin, and glamour girl. She worked her way out to Canada as a stewardess and back again when she'd had enough. She then married a rather worthless playboy racing-motorist who was pretty poor both in money-sense and woman-sense. She had to sell her jewels to keep him, and to work in a hat-shop to earn the rent for their flat. He contributed nothing unless he backed a winner with his pocket-money, when they blued it with the greatest enjoyment. It was only when he diverted her hard-earned rent to another woman's lap that she protested, walked out on him, and put in her papers for a livorce.

We next find her settled down comfortably as a young armer's wife, leading a happy outdoor life, riding, rearing, and breaking in colts, tending the poultry-farm, and having ovely fun in the kitchen. It was an idyllic existence. The oung couple were deeply in love with each other and the oung farmer lavished all the good things on her that she had ked before.

After a couple of years she developed a small patch in one ung and reddening of one arytenoid. These were discovered lmost accidentally, one might say, owing to the thoroughness f her general practitioner; for there were no physical signs. t was for other symptoms she consulted him. She was six eeks' pregnant. In accordance with general usage she was dvised to have therapeutic abortion, and this was done. After which no time was lost getting her under sanatorium treatment, where she was put on absolute rest.

From the hardships she had gone through she might have een by now a hard-mouthed hard-bitten disillusioned young oman; but she was not. She was one of the sunniest and weetest young women I have ever met. Nothing disturbed er infectious gaiety. She bubbled with fun and friendliness. verybody fell for her, women in particular. She had managed acquire and cherish somehow delight in poetry, music, nd sketching (Corot, Debussy, and Swinburne). She was the dored adopted aunt of about half a dozen children.

Her tuberculosis spread in both lungs, larynx, and trachea. Each X-ray film showed advancing shadows, until each lung looked like a snow-storm. She had to talk in whispers, and her swallowing of food was painful to watch. It was evident that she was going to die, and that nothing could be done.

A week or so before the end she developed a strong positive transference towards me; so I took to sitting with her at night when her dyspnœa frightened her, until her opiate took effect and she dropped off to sleep.

It was then that I learned her history and her bewildered attitude towards it. Her divorce had never gone through; so she had never been able to marry Bill, the young farmer. But that didn't worry her in the least; to her it was perfectly natural and right that she should make him happy. There was no feeling of guilt. She adored him; and her life with him and the horses, the ducks and the goats, *was* idyllic—but it was somehow *unreal*. Even had she been legally married to Bill, she would have continued to feel that her first unhappy marriage was the real one. Miserable and exasperated often, insecure always as she had been with the playboy, it was the small memories of midnight feasts—of a stray kitten they adopted on Christmas Eve and played with on the bed—it was memories like these that kept crowding in now. And then she said something startling. Without rancour or self-pity, without question and with complete acceptance, she said, "It looks as if I have a *need* to suffer." She died that night. There was no mistake about the dose of morphia.

I feel that her history is worth giving in some detail, because it has features in common with two other women patients. In all three cases there had been an unhappy but curiously vital first marriage, and a brief glimpse of happiness and security in a second unlegalised alliance, which seemed to them unreal and dreamlike in comparison. In all three the disease was diagnosed early and brought early to treatment without avail. They all lost their good looks and became skull-faced, with bodies and legs bloated with œdema. All three had sweet sunny dispositions; which persisted undimmed to the end in spite of their afflictions.

I must confess I am most puzzled and somewhat dismayed. Mere external happiness, adjustment to the outer world, doesn't seem enough.

CONFOUNDING THE DOCTORS

My last case is very different.

Gladys I first saw when I was still in general practice in 1933. She was aged about 19 and was a cheerful, cow-like, but rather slovenly cook-general in a farmer's household. I was attending the farmer, and, as I made my way out one day through the kitchen she told me she had been coughing up some blood and asked, "Did it make any difference?" Well, she was a real Queen Square conjoint case—bilateral excavation and a family history riddled with phthisis.

She was admitted forthwith into a sanatorium and discharged at the end of the statutory three months "improved." True she had gained a lot of body-weight and looked fitter, but the activity of her disease, although doubtless lessened, merited at least another three months on absolute rest, with a campaign to eliminate her cavities. She went home, and was on the club; and then she moved from the district and I lost track of her.

When she next came to me she was seven months' pregnant and had been married very nearly as long. She was pretty well, but I dreaded the labour and the puerperium. I can't remember the labour—it was probably a B.B.A.—but her disease *did* flare up and spread during the puerperium as I had feared; and with great difficulty I kept her in bed at home for three months. In fact she was still in bed when I sold out of the practice. Before abandoning her I told her she must never do it again and gave her explicit instructions how not to do it again. And had to add that it was nothing to giggle at either.

Some seven years later, in 1942, I spent my summer holiday doing a locum in my old practice—a fascinating and unique opportunity for follow-up which I could not resist. I was asked to call in and see Gladys, when I was passing that way, because of some hæmorrhage, and I was surprised thus to learn that she was still alive, and marvelled at her tenacity to life.

I called and found her spooning out dinner to nine children all below the age of $7^1/_2$. The children were singing and hammering the table with their spoons like the Christmas carol, while she sat placid and cow-like, smiling on her brood. The din was terrific.

The hæmorrhage was from a cervical erosion. She was not pregnant at the moment; so I persuaded her to have a further overhaul and radiography of her chest. The cavities, one of which used to be the size of a tangerine orange, had disappeared completely. There was plenty of firm-looking scar tissue but no sign of any activity.

I simply could not explain it; but, when her husband came in, I seemed to see daylight. He was an ordinary farm labourer, a cheerful good little worker, and a good family man. Though desperately poor and living primitively in a condemned cottage they were wildly happy and laughed a lot.

Here then is a matter for discussion. What made Gladys's disease, which was definitely *advanced* and progressive seven years before, heal in spite of the continued presence of all these classical adverse conditions? Why did she do better than our sanatorium patients? Can it have been sheer contentment? Or can it have been contentment plus the gratification of her deep creative impulse?

That raises another point. Phthisiologists make it a rule to forbid women to have babies for as long as five years after the cessation of all symptoms of activity, because of the tragedies which are apt to occur during the puerperium if the disease has not long been arrested, and is still latent.

All are agreed that the tuberculous woman often does phenomenally well during her pregnancy—even in the early months before the enforced rise of the diaphragm and the restriction of its movements can play any part in the mechanical relaxation and immobilisation of the lesions. It is, some say, as if some fœtal hormone assisted the mother's tissues to arrest the disease. Be that as it may, it is certainly the abrupt diaphragmatic descent during parturition which is responsible for the massive basal spread during the puerperium which is so often fatal.

Nowadays I take the line that this danger can be obviated successfully by the immediate induction after labour—or better still after cæsarean delivery—of a pneumoperitoneum; so that the volume of the pregnant uterus is replaced by an equivalent volume of air, to keep the diaphragm tented up. This may well be reinforced by phrenic interruption on the more threatening side. So far, in the few cases where this has been done, it has worked out very well.

Should this prove to make parturition less dangerous, I cannot help wondering whether pregnancy may not be a good therapeutic prescription, in appropriate cases, not only because of its mechanical and alleged endocrine advantages but also because it satisfies a deep-rooted instinct, and the patient is thereby granted a brand-new squalling reason for not dying.

Looking back I wonder if Peggy, the farmer's wife, might not have lived had her pregnancy been allowed to come to term.

NATURE OF THE DISEASE

My tentative conclusions are that patients who develop pulmonary tuberculosis in the absence of any of the classical physical environmental causes often do so because of dis-ease in their psychological environment—their relation to themselves or to the world outside.

We are all agreed that certain physical distressing circumstances lower a patient's resistance to disease, but that is only an empirical phrase to cover everyday experience. We really know nothing yet about the biochemical tissue changes (if any) that are involved when "resistance is lowered." We are only saying really that the soil is being made ready for the seed. The patient's tissues are ready to be diseased. In psychological distress the patient as a whole is ready to be ill—in fact is ill already. And the ubiquitous bacilli both *endogenous and exogenous are there ready to* oblige.

This is tantamount to saying that tuberculosis provides means for a flight from frustration, for self-punishment and all those other dark urges which are continually shipwrecking our best behaviour. I believe this, with half of me; but my alter or super ego would like to have mathematical confirmation. I cannot be whole-hearted until we can measure in grammes per litre the presence or absence of disease-resisting substances in the body fluids.

Even if we cannot accept that thesis fully, I think we must agree to the generalisation that every individual *reacts to a disease according to his personality*; from which it must follow that the psychoneurotic, when given a touch of tuberculosis, will exploit his disease process to suit his pattern of living—or of dying. Moreover, such a patient may develop a secondary reactive personality, of which the disease is a complementary and necessary part, as in the "Dornford Yates syndrome" I described earlier.

Obviously, if such a patient is to recover from his tuberculosis, we must treat more than the local lesions and the toxic manifestations. His concurrent psychological dis-ease must be alleviated, and alleviated in good time, if he is to recover and not become chronic or incurable. Time itself is notoriously a great healer in cases of emotional maladjustment that are not basic. The period of retreat in a sanatorium—that mother figure—brings about changes in both the inner and outer lives of many, probably most patients. They overcome the disease *when they are ready*. But for quite a few cases it would be as well if psychiatric help and guidance were at hand to expedite their readjustment.

POSTSCRIPT, 1946

The foregoing was written and delivered before I had received any psychiatric training or had been taught the correct terminology. I have since learned by experience in *Army psychiatry that it* is not always necessary to raise conflicts and forgotten traumata to the conscious level. In a vast majority of everyday cases there is no more need to drag in—or drag out—the ubiquitous Œdipal Situation than there is to invoke the Second Law of Thermodynamics when soldering a kettle. Therapy can operate directly on the unconscious, giving it, as it were, a wholesome tweak which helps it to unravel itself. It is hard to understand how this happens, but no harder perhaps than understanding how many trusty empirical treatments—such as hot-water bottles, deep massage, and bottles of medicine—alleviate concealed underlying organs in distress. Both patient and physician are equally in the dark as to what really happens inside, but whereas *the patient* accepts the change gladly and unquestioningly, the physician cherishes a Scientific Hypothesis.

I have spared the reader—and myself—a great deal of trouble by refraining from rewriting the paper in the correct terminology.

"... The principal beneficence of a university should be that it stimulates an appetite for knowledge and understanding. You must not, of course, expect to *receive* education from your university; for a university that offered an orderly, finite, and readily comprehensible scheme of education—education as differenced from instruction—could only exist as th political instrument of a despotic or total State. To acqui education you must reach out for it. *You cannot obtain* i by sitting down as if to three rationed courses in a workers canteen; the process is more like picking blackberries, an some of the fruit you gather will certainly be green and caus distress."—ERIC LINKLATER in a rectorial address at Aberdee University, Oct. 26.

THE POLIOMYELITIS EPIDEMIC IN MAURITIUS

IN 1945

NICAL FEATURES AND ORGANISATION OF TREATMENT

H. J. SEDDON

THE UNIVERSITY OF OXFORD

E. I. B. HAWES
E SQUADRON-LEADER R.A.F.V.R.

J. R. RAFFRAY
CAPTAIN R.A.M.C.

A MAJOR epidemic of poliomyelitis is always a serious tter. Where conditions are primitive and the medical vices exiguous, such an event is catastrophic; and may therefore be of interest to describe the measures ken for dealing with the recent outbreak in Mauritius. On March 21, 1945, one of us (H. J. S.) was informed the Colonial Office that poliomyelitis had broken t in Mauritius, and was asked to go there as quickly possible to do whatever was necessary for the care of se affected. As an island epidemic is a particularly vourable subject for epidemiological investigation, e Medical Research Council agreed to second Dr. A. M. cFarlan to conduct a survey. Miss Crossley, a physioherapist from the Wingfield-Morris Hospital, Oxford, as also a member of the party, and we left England y air on April 7.

Since it seemed likely that one of the greatest difficulties ould be shortage of staff—there are too few doctors in lauritius—we asked Lieut.-General Sir Alexander Hood, G.A.M.S., if he would allow one or more Army medical ficers serving in Africa to be seconded for work in Mauritius. is response was characteristically generous, and we were iven leave to discuss recruitment with the appropriate irectors of medical services. We were most hospitably ceived in Cairo by Major-General J. C. A. Dowse, and it as agreed that two men from M.E.F. would be sent to lauritius if East Africa were unable to spare anyone. However, we found Brigadier R. P. Cormack, E.A. Command, willing and able to help; Major G. W. A. Dick was ermitted to join Dr. McFarlan, and the services of two Mauritian Army doctors stationed in the island, Major L. de Chazal and one of the writers (J. R. R.), were promised. Another of the writers (E. I. B. H.) was stationed in Nairobi t the time and was permitted by Air Vice-Marshal Sir Brian aker to join the party. It was also agreed that we might all on the R.A.F. for supplies of 'Duralumin' required for aking splints, and that free use should be made of the air ansport service for the conveyance of pathological material om Mauritius to Uganda. Arrangements had been made or sending specimens for animal inoculation to Dr. K. C. mithburn at the Rockefeller Yellow Fever Research Institute t Entebbe.

We reached Mauritius on April 15 and started work n the following day. The island is some 38 miles from orth to south and 28 from east to west, and is situated the Indian Ocean about 600 miles east of Madagascar d 20 degrees south of the Equator. The total population is about 419,000; Indians (265,000) predominate d are mostly descendants of indentured labourers; ere are roughly three times as many Hindus as oslems. The 143,000 Creoles are descendants of African d Malagasy slaves. More recent arrivals are the hinese (10,000), who are almost all shopkeepers. The d-established colonists are of French descent and are latively few; and there is a sprinkling of people om the United Kingdom. The economy of the island epends almost entirely on its chief product, cane sugar.

FIELD ORGANISATION

By the time we arrived Dr. A. Rankine, director of edical and health services, had received notifications over a thousand cases. Dr. McFarlan decided that m the epidemiological standpoint it would be best start work in Savanne, a rural area with small communities, in which cases were still occurring at the time of our arrival. He then proposed to tackle an urban area (Port Louis, the capital); next Pamplemousses, a rural district adjoining the urban area of Port Louis; and finally the Rosehill district in which it was believed the epidemic began. From the clinical standpoint it hardly mattered where we started, but we thought it would be best to follow the epidemiologists.

The plan of campaign was as follows. The list of notifications gave a rough indication of the extent of the outbreak in each of the nine districts of the island. We tackled each district in turn. The government (district) medical officers, sanitary inspectors, health guards, sugar-estate doctors and dressers, and the village schoolmasters were most helpful in guiding Dr. McFarlan and Major Dick to the homes of patients (a few were already in hospital); but the detailed hunting down—there is no other way of describing it—could be done only by full-time workers. We were lucky to have some V.A.D. nurses at our disposal, intelligent young ladies from French families who knew every part of the island intimately and were fluent in its Creole patois. They soon became so efficient that it was possible to entrust them with many of the detailed inquiries appearing on the special case-sheet which we devised. As they collected their data Dr. McFarlan, Major Dick, and the V.A.D. nurses arranged for the patients to be sent to a convenient centre, such as a district or sugar-estate hospital, dispensary, or schoolroom, where we examined them one or two days later.

Muscle charts were used on which the extent of the paralysis was recorded according to the system of grading approved by the peripheral nerve injuries committee of the Medical Research Council (1943). The thorough examination of the muscles of a small child is laborious and time-consuming; but, unless observations are made in fair detail, there is no sure foundation for classification, prognosis, or treatment. The three of us were sometimes able to examine as many as 60 cases a day, though this is not to be recommended when working in a tropical climate. Those who required splints were measured for them, and lists were made, in order of urgency, of patients in need of hospital treatment. Few parents refused to allow their children to come into hospital; this was largely due to the powers of persuasion of the V.A.D.'s, though their approach was entirely objective and no specious promises of cure were made. At times the clinical team went ahead of the epidemiologists in order that as many patients as possible might be seen; but where this was done the attendances were rather less satisfactory and a second visit was usually necessary after the V.A.D.'s had rounded up the stragglers.

Information about the disease and its treatment was disseminated by broadcasts, and the distribution of printed versions of the broadcast talks; the press was most helpful throughout, the articles and reports that appeared being accurate and balanced. Lectures and demonstrations were given to doctors, and one lecture to school-teachers from every part of the island.

Most of our evenings were devoted to sorting out notes and orders for splints, and analysing data, and the volume of clerical work soon became considerable. Here again the Army came to the rescue; we were provided with two clerks from the A.T.S. and two from the R.A.M.C. Mrs. Moody, wife of the Colonial Secretary, and Mrs. Ward, wife of the Director of Education, also devoted many hours to the thankless task of making duplicates of the case-notes.

CLINICAL FEATURES

This paper summarises the clinical features of the outbreak, the epidemiological findings having been described elsewhere (McFarlan et al. 1946).

On account of our relatively late arrival, no search was made for non-paralytic cases. This would have been a tedious and time-consuming task because it would

More or less involvement of the trunk muscles was und in 85 cases in the sample: therefore a watch for the velopment of spinal curvature will have to be kept in out 170 cases—a very considerable number.

So far as treatment was concerned, we divided the tients into three groups:

Those with complete paralysis of one or more limbs sisting for 3–4 months.—According to Harry (1938) e prognosis in such cases is bad, and recent experience as confirmed his view. We therefore decided not to tain children so affected in hospital for a long period; hen it was clear that there was persistent total paralysis f a lower limb, an appliance was supplied, and the hild was discharged as soon as he could walk.

Patients with paralysis of the trunk muscles.—It was hought wise to retain such cases for a long period, ursing them in strict recumbency, in the hope of minimising the incidence of scoliosis and the need for supplying spinal or abdominal supports.

Patients with moderate paralysis, showing some improvement.—All these children have been treated intensively, and inpatient treatment will be continued until serial muscle charts show that no further improvement is occurring.

THE EMERGENCY HOSPITAL

In Mauritius there are barely enough hospital beds for the ordinary needs of the population. When Brigadier E. R. Cullinan, consulting physician, E.A. Command, visited the island towards the end of March, he urged the necessity for the immediate establishment of one large central emergency hospital, and as a result of his advice Colonel Ronald Yeldham handed over to the medical and health department a collection of huts on the racecourse at Floreal. The site was pleasant and healthy and the huts well built; the difficulty was to equip and open them within reasonable time; there had been three hurricanes between January and April, which had caused widespread damage, and there was shortage of labour and materials.

Although the conversion of the buildings began on April 9, the opening of the wards failed to keep pace with the enrolment of patients for admission, and we found ourselves in the unexpected and embarrassing position of being unable to deal adequately with the results of our propaganda. Parents brought their children to the gate of the hospital and demanded admission. We were equally anxious to get all the children who eeded treatment, about 420 out of the 1000, into ospital as quickly as possible, so that at least the evelopment of contractures might be prevented. As a emporary measure, admittedly unsatisfactory but better han nothing, some of the less urgent cases were admitted o sugar-estate hospitals and fitted with appropriate pparatus pending the opening of more wards at Floreal.

TABLE IV—INCIDENCE OF PERMANENT CRIPPLING

Sample: 500 cases—i.e., about half of the total

	Cases	
Died	29	(5·8%)
Early recovery	157	(31·4%)
Some weakness of one lower limb	130	(26·0%)
Both lower limbs affected; able to walk with difficulty and only if supplied with appliances	35	(7·0%)
Paralysis of both lower limbs and more or less involvement of trunk muscles; will get about only with great difficulty	29	(5·8%)
Paralysis of one upper limb, proximal segment	26	(5·2%)
Both lower limbs affected; likely to walk well with appliances	24	(4·8%)
Complete paralysis of one upper limb	16	(3·2%)
Widespread paralysis: may be bedridden	13	(2·6%)
Paralysis of one lower limb and trunk muscles; may walk well with appliances	11	(2·2%)
Paralysis of one upper and both lower limbs	10	(2·0%)
Paralysis of one upper and one lower limb	7	(1·4%)
Paralysis of trunk muscles alone	5	(1·0%)
Paralysis of face	3	(0·6%)
Paralysis of one upper limb, distal segment	2	(0·4%)
Paralysis of neck	2	(0·4%)
Paralysis of both upper limbs	1	(0·2%)
Total	500	

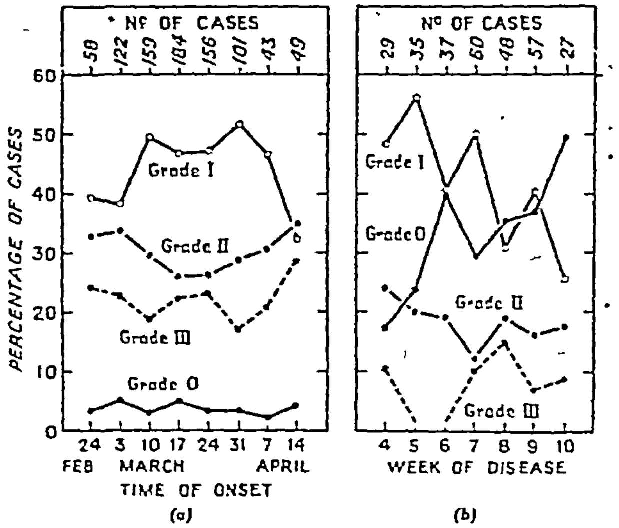

Fig. 1—Severity of paralysis, as determined by (a) history and (b) clinical examination. For explanation of grades see text.

In response to an appeal made to all the East African colonies Dr. and Mrs. H. B. Cumpston came to Mauritius, and they were appointed medical superintendent and matron of the hospital. The services of an Army sister were placed at our disposal by Lieut.-Colonel Leake, O.C. Station Hospital; in May, Dr. Henry de Boer, director of the Uganda Medical Service, sent one of his nursing sisters, and another Army sister was sent from Nairobi by Brigadier Cormack. The junior nursing staff consisted entirely of V.A.D.'s; they lacked experience and were imperfectly trained, but their enthusiasm and devotion to their work were most encouraging and they learned quickly from lectures and ward instruction.

TREATMENT

General Hygiene.—The huts were thoroughly cleaned and sprayed with D.D.T. before occupation. When a child was admitted, all its clothes were left outside. In almost all cases the hair was cropped short, and, after bathing, skin infections were promptly treated with appropriate ointments and paints. A child with poliomyelitis cannot be properly treated unless its skin is healthy. We were afraid that this rather drastic initiation might be resented by some parents, but it was not—they thought it was a necessary part of the treatment, as indeed it was.

Splints.—Plaster-of-paris is of little value for prolonged splinting of the lower limbs of small children (and in poliomyelitis the lower limbs are mostly affected), since it is easily soiled and disintegrates rapidly if wet with urine. Metal is essential, and experience of the Malta epidemic confirmed one's preference for duralumin. The Government of Malta sent the duralumin splints that had been used in the 1942–43 epidemic (Agius et al. 1945); after minor repairs all were fit for use, and we hastened to supply them to those patients whom they happened to fit.

It was agreed that one of us (E. I. B. H.) should be solely responsible for the supply of apparatus, and it was found that the workshops at H.M. prisons offered the best facilities for splint-making. There were no difficulties about shortage or impermanence of labour; and the costs of production were very low. Within a few weeks the Senior Chief Officer (Mr. W. McCormack) organised a skilled industry entirely new to the prisons; and the prisoners, many of them desperate criminals, were soon turning out large numbers of accurately fitting splints. Their sympathy and interest were aroused to such an extent that they devoted such spare time as they had to making toys for the children. And one evening, after they had finished installing some apparatus at the hospital, three reprieved murderers were found visiting each ward in turn and solemnly presenting toys to about a hundred small patients.

have been necessary to distinguish carefully between abortive attacks of poliomyelitis and mild recrudescences of malaria. About 96% of the patients whom we saw were or had been paralysed. Over 900 patients were examined; but, since some were not seen until shortly before our departure, we had to be content with more limited numbers for statistical analysis.

TABLE I—SITE OF INVOLVEMENT OF CENTRAL NERVOUS SYSTEM

Site	Lumbar	Lumbar and cervical	Cervical	Medulla	Uncertain	Total
No. of cases	258 (*64·3 %*)	88 (*22·0 %*)	38 (*9·5 %*)	10 (*2·5 %*)	7 (*1·7 %*)	401

Age-incidence.—Of 851 cases, 63·9% were in children aged 0–4 years and 30·9% in children aged 5–9. The extremes were a child aged 2 months and a man of 61.

Site of Paralysis.—Analysis of 401 case-histories gave an estimate of the frequency with which various parts of the central nervous system were affected (table I). *The lumbar enlargement was affected in 86·3% of cases.*

In 212 cases where only one side was paralysed there were 109 with paralysis of the left side and 103 with paralysis of the right. This equality was found in the subgroup with paralysis of one lower limb or of one lower and one upper limb, but in the 32 patients with paralysis of one upper limb only there were 21 with paralysis of the right and only 11 with paralysis of the left; this finding supports the suggestion made by several authors on clinical grounds, and supported by experimental evidence (Levinson et al. 1945), that the extent to which a part is used may have some bearing on the location of paralysis.

It has been said that trauma may also play some part in determining the site of paralysis. Of 8 cases with a history of trauma in the fortnight before illness, 3 later had paralysis of the lower limb which had been injured, and in 1 of them the other lower limb was also affected. In the remaining 5 cases the site of paralysis bore no relation to the site of injury.

Injections of quinine into the gluteal muscles had been given to 28 children during the fortnight before the onset of poliomyelitis. There were 13 to whom one injection was given; in 7 paralysis later appeared in the lower limb of the side on which the injection had been made, and in 6 the paralysis affected the lower limb of the opposite side. Injections into both buttocks had been given to 15 children; in 11 paralysis of both lower limbs followed, and in 4 paralysis of one lower limb. In none of these cases was paralysis due to action of the quinine on the sciatic nerve, though some such cases were seen. There was no convincing evidence of a relationship between the site of injections and the site of subsequent paralysis.

TABLE II—PERCENTAGE OF CASES WITH EACH GRADE OF PARALYSIS AS DETERMINED BY HISTORY

Grade	O	I	II	III	IV	Cases
Cases with onset—						
(*a*) before Feb. 24 or after April 8 ..	3·7	35 5	34·7	8·4	17·7	107
(*b*) between Feb. 25 and April 7 ..	3·8	46·7	28·7	10·0	10·8	765
All cases.. ..	3·8	45 3	29·4	9 8	11·7	872

Severity of paralysis in 872 cases, including 58 deaths, was roughly assessed in four grades according to the maximal extent of paralysis as determined by history (table II). Grade O comprised patients with weakness only but with clinical and epidemiological findings which made the diagnosis reasonably certain. In other cases paralysis of the face, neck, back, or respiratory muscles, or medullary paralysis was reckoned as equivalent t involvement of a limb, and grades I, II, and III com patients with paralysis of one, two, or three "limb respectively. Grade IV included patients with pa of four or more "limbs."

Paralysis of one "limb" was most common, and two "limbs" next most common. When the c were arranged according to the week of onset, it found that during the six weeks from Feb. 25 to Apri when the epidemic was at its height, there was a hi percentage than in earlier or later weeks of cases one limb paralysed and a lower percentage of cases two or more limbs paralysed. This suggests that the peak of the epidemic, as compared with earlier later periods, the virus was causing paralysis in m persons who had sufficient immunity to localise t infection to one part of the spinal cord. Faber et (1943) have provided some evidence of such immuni in cynomolgus monkeys after exposure of mucosa poliomyelitis virus. The percentage of cases in grade was the same in both periods; but little significance c be attached to this finding, since no particular sear for such cases was made; there were only *33 grade* cases among the 872.

The severity of paralysis in 293 cases was assess in a similar fashion on the results of clinical examinatio

TABLE III—PERCENTAGE OF CASES WITH EACH GRADE SEVERITY AS DETERMINED BY CLINICAL EXAMINATION

Week of disease	Grade of severity				Case
	O	I	II	III	
–4	17·3	48·4	24·1	10 2	29
5	24·0	56·0	20 0	..	35
6	40·0	40·5	19·0	..	37
7	28·2	50·0	11·8	10·0	60
8	35·4	31·1	18·9	14·6	48
9	36·8	40·4	15·8	7·0	57
10 +	48·2	25·9	17·4	8·5	27
All cases	32·7	42·3	16·5	8·5	293

It was found (table III and fig. 1) that the percentage recoveries (grade O) increased, and the percentage of singl limb paralyses (grade I) decreased, with the time elaps between the onset of illness and the day of examinatio

Hence, if the results of clinical examination we used to compare the severity of groups of cases, or cases in different epidemics, it would be necessary take into account the duration of illness at the time examination. In Mauritius the cases in Savanne appear *to be more severe than in Pamplemousses*, but t explanation was that in Savanne the epidemic was la and examinations were made early, whereas in Pamp mousses the reverse was the case. *Table III gives s indication of the average rate of recovery* during second month of the disease, but the estimate is clea less satisfactory than one obtained from successi examinations of the same patients.

Another analysis (table IV) was made to determine t incidence of permanent crippling; the figures were necessity provisional, since it was too early to ass the prognosis in all cases with much accuracy.

From this table we may deduce that the inciden of crippling (per thousand cases the approxima total) will be as follows:

Lower limbs: slight	Rather less than 260
" " moderate	" " 48
" " considerable	About 70
" " and trunk: much disability	Rather less than 80
Upper limbs: only slight	About 40
" " one useless	Rather less than 36
Bedridden	About 25

More or less involvement of the trunk muscles was ound in 85 cases in the sample: therefore a watch for the evelopment of spinal curvature will have to be kept in bout 170 cases—a very considerable number.

So far as treatment was concerned, we divided the atients into three groups:

Those with complete paralysis of one or more limbs xisting for 3–4 months.—According to Harry (1938) he prognosis in such cases is bad, and recent experience as confirmed his view. We therefore decided not to etain children so affected in hospital for a long period; hen it was clear that there was persistent total paralysis f a lower limb, an appliance was supplied, and the hild was discharged as soon as he could walk.

Patients with paralysis of the trunk muscles.—It was hought wise to retain such cases for a long period, ursing them in strict recumbency, in the hope of minimising the incidence of scoliosis and the need for supplying spinal or abdominal supports.

Patients with moderate paralysis, showing some improvement.—All these children have been treated intensively, and inpatient treatment will be continued until serial muscle charts show that no further improvement is occurring.

THE EMERGENCY HOSPITAL

In Mauritius there are barely enough hospital beds for the ordinary needs of the population. When Brigadier E. R. Cullinan, consulting physician, E.A. Command, visited the island towards the end of March, he urged the necessity for the immediate establishment of one large central emergency hospital, and as a result of his advice Colonel Ronald Yeldham handed over to the medical and health department a collection of huts on the racecourse at Floreal. The site was pleasant and healthy and the huts well built; the difficulty was to equip and open them within reasonable time; there had been three hurricanes between January and April, which had caused widespread damage, and there was shortage of labour and materials.

Although the conversion of the buildings began on April 9, the opening of the wards failed to keep pace with the enrolment of patients for admission, and we found ourselves in the unexpected and embarrassing position of being unable to deal adequately with the results of our propaganda. Parents brought their children to the gate of the hospital and demanded admission. We were equally anxious to get all the children who needed treatment, about 420 out of the 1000, into hospital as quickly as possible, so that at least the development of contractures might be prevented. As a temporary measure, admittedly unsatisfactory but better than nothing, some of the less urgent cases were admitted to sugar-estate hospitals and fitted with appropriate apparatus pending the opening of more wards at Floreal.

TABLE IV—INCIDENCE OF PERMANENT CRIPPLING

Sample: 500 cases—i.e., about half of the total

	Cases	
Died	29	(5·8%)
Early recovery	157	(31·4%)
Some weakness of one lower limb	130	(26·0%)
Both lower limbs affected; able to walk with difficulty and only if supplied with appliances	35	(7·0%)
Paralysis of both lower limbs and more or less involvement of trunk muscles; will get about only with great difficulty	29	(5·8%)
Paralysis of one upper limb, proximal segment	26	(5·2%)
Both lower limbs affected; likely to walk well with appliances	24	(4·8%)
Complete paralysis of one upper limb	16	(3·2%)
Widespread paralysis: may be bedridden	13	(2·6%)
Paralysis of one lower limb and trunk muscles; may walk well with appliances	11	(2·2%)
Paralysis of one upper and both lower limbs	10	(2·0%)
Paralysis of one upper and one lower limb	7	(1·4%)
Paralysis of trunk muscles alone	5	(1·0%)
Paralysis of face	3	(0·6%)
Paralysis of one upper limb, distal segment	2	(0·4%)
Paralysis of neck	2	(0·4%)
Paralysis of both upper limbs	1	(0·2%)
Total	500	

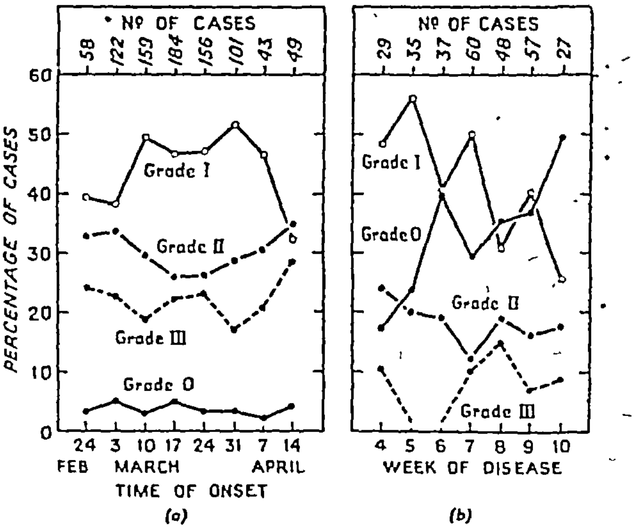

Fig. 1—Severity of paralysis, as determined by (a) history and (b) clinical examination. For explanation of grades see text.

In response to an appeal made to all the East African colonies Dr. and Mrs. H. B. Cumpston came to Mauritius, and they were appointed medical superintendent and matron of the hospital. The services of an Army sister were placed at our disposal by Lieut.-Colonel Leake, O.C. Station Hospital; in May, Dr. Henry de Boer, director of the Uganda Medical Service, sent one of his nursing sisters, and another Army sister was sent from Nairobi by Brigadier Cormack. The junior nursing staff consisted entirely of V.A.D.'s; they lacked experience and were imperfectly trained, but their enthusiasm and devotion to their work were most encouraging and they learned quickly from lectures and ward instruction.

TREATMENT

General Hygiene.—The huts were thoroughly cleaned and sprayed with D.D.T. before occupation. When a child was admitted, all its clothes were left outside. In almost all cases the hair was cropped short, and, after bathing, skin infections were promptly treated with appropriate ointments and paints. A child with poliomyelitis cannot be properly treated unless its skin is healthy. We were afraid that this rather drastic initiation might be resented by some parents, but it was not—they thought it was a necessary part of the treatment, as indeed it was.

Splints.—Plaster-of-paris is of little value for prolonged splinting of the lower limbs of small children (and in poliomyelitis the lower limbs are mostly affected), since it is easily soiled and disintegrates rapidly if wet with urine. Metal is essential, and experience of the Malta epidemic confirmed one's preference for duralumin. The Government of Malta sent the duralumin splints that had been used in the 1942–43 epidemic (Agius et al. 1945); after minor repairs all were fit for use, and we hastened to supply them to those patients whom they happened to fit.

It was agreed that one of us (E. I. B. H.) should be solely responsible for the supply of apparatus, and it was found that the workshops at H.M. prisons offered the best facilities for splint-making. There were no difficulties about shortage or impermanence of labour; and the costs of production were very low. Within a few weeks the Senior Chief Officer (Mr. W. McCormack) organised a skilled industry entirely new to the prisons; and the prisoners, many of them desperate criminals, were soon turning out large numbers of accurately fitting splints. Their sympathy and interest were aroused to such an extent that they devoted such spare time as they had to making toys for the children. And one evening, after they had finished installing some apparatus at the hospital, three reprieved murderers were found visiting each ward in turn and solemnly presenting toys to about a hundred small patients.

thus there is a round opening behind the knee. Two slots, 1 in. × $^{1}/_{4}$ in., are cut one on each side, $^{1}/_{4}$ in. from the lateral margin and 1 in. from the proximal end.

The thigh- and calf-pieces are joined at an angle of 15°, so that the foot-piece and the upper end of the thigh-piece both rested on the bed, with the contained limb in a comfortable position.

Calf-piece.—Unless it is for a short splint a half-circle is cut in the proximal edge, corresponding with that in the thigh-piece. Two slots are cut in the upper end similar to those in the thigh-piece, and two slots in the lower end set obliquely at 45° across the corners. The lower edge, and for a short splint the upper also, is moulded outwards to prevent chafing.

Foot-piece.—Shaped roughly like the sole of a boot. Two slots, 1 in. × $^{1}/_{4}$ in., cut one on each side, halfway along the length and $^{1}/_{4}$ in. from the edges.

Connecting L-piece.—Width $^{1}/_{2}$–1 in. according to size of splint. The straight portions of the L are riveted to the calf-piece for half its length and to the foot-piece for the whole of its length. There is a wide U-bend, $1^{1}/_{2}$–3 in. wide and deep, at the angle of the L, to accommodate the heel. A $^{3}/_{8}$ in. screw is riveted into the curve of the U to fit into the slot in the cross-bar.

Cross-bar.—For a single splint this consists of a straight strip 2–3 × 6–8 in. A hole is drilled in the centre to take the screw mentioned above. The bar is turned at right angles along its edges for greater strength.

The cross-bar for a double splint is curved, the curve being the quadrant of a circle of radius equal to the length of the lower limb. Slots are cut in the bar to allow variation in the degree of abduction.

MEASUREMENTS

The measurements supplied to the instrument-maker are body measurements, from which he works out the splint measurements as described below. The calculations are accurate for average-sized splints, and certain obvious allowances must be made for very large or small splints. The measurements of width for the thigh- and calf-pieces are on the flat before bending into an arc slightly wider than a semicircle.

Great trochanter to external condyle of knee	Subtract 3 in.	= Length of outer edge of thigh-piece
External condyle of knee to sole of foot	Subtract 2 in.	= Length of calf-piece for long splint
	Subtract 4 in.	= Length of calf-piece for short splint
Girth of thigh at groin ..	Divide by 2	= Breadth of thigh-piece at upper end
Girth at knee	Divide by 2	= Breadth of thigh-piece at lower end, and breadth of calf-piece at upper end
Girth above malleoli ..	Divide by 2	= Breadth of calf-piece at lower end
Length of foot, heel to great toe	Add 2 in.	= Length of foot-piece
Breadth of forefoot ..	Add $^{1}/_{2}$ in.	= Breadth of foot-piece at widest point
Breadth of heel ..	Add $^{1}/_{2}$ in.	= Breadth offoo t-piece at heel

Upper-limb abduction splint

This was designed for ease of manufacture and comfort in wearing both when in bed or when ambulatory. The framework is made from duralumin, mild steel, or brass rod of a gauge of $^{5}/_{16}$ in. for large splints and proportionately smaller gauge for small splints.

The frame is covered throughout with leather and padded in its vertical component and at the waist. A canvas bodice with shoulder-straps is sewn on to the posterior part of the chest-piece and fastened with two buckles and straps. The shoulder-straps are adjustable with buckles sewn on the front of the bodice. The bodice is cut away under the axilla to prevent chafing.

The width of the splint averages 3 in. for a medium-sized child aged 3–5 years, and 4–5 in. for adults. The width is the same from the hand to the crest of the ilium, where the splint broadens out to encompass nearly half the girth at the waist. The waist-piece is curved in two dimensions to fit round the waist and follow the curve of the crest of the ilium. It is about 2 in. wide and is well padded. The hand-piece is about 1 in. wider and is padded to give a comfortable grip.

MEASUREMENTS

Measurements are given for the frame only, since it found that measurements for the bodice were best taken the tailor who could then ensure a perfect fit.

From posterior axillary fold, or middle of the head of the humerus, to the tip of the olecranon	Add $^{1}/_{2}$ in.	= Length of outer or terior rod of arm tion
From axilla to crest of ilium	Add $^{1}/_{2}$ in.	= Length of vertical and length of oute of forearm portio
Half the girth at waist ..	Divide by 2	= Length of waist-piec

Bradford frame

The metal frame (fig. 4) is made from mild steel tu with an internal diameter of $^{1}/_{2}$–$^{3}/_{4}$ in. and painted or spr with aluminium paint. It is rectangular, with rour corners.

The frame is supported on two wooden blocks 4 in. and hollowed out to reduce weight. The frame fits grooves in the blocks and is held down with metal st The frames are covered by two canvas slings, laced un neath; a gap of 4–6 in. is allowed between the two canv to prevent soiling and to allow the use of a bedpan.

Where double gutter splints are required the lower car can be dispensed with, a wooden bar being fixed across frame to support the splints under the thigh-pieces (fig.

MEASUREMENTS

From vertex to sole of heel ..	Add 4 in.	= Length of frame

PENICILLIN FOR GONORRHŒA IN THE FEMALE

W. Neville Mascall
M.R.C.S.
DIRECTOR, L.C.C. (ENDELL STREET) CLINIC

In the past gonorrhœa in the female has seld received the attention which it deserves from the medi profession; and in recent years the introduction of n and effective remedies has detracted from an inter which was never strong, for there is a tendency to as that these infections are easily cured and are not acco panied by serious after-effects. There is still no genu recognition of the fact that this is a most damag complaint, with far-reaching consequences, unless trea skilfully in its early stages. What Thomson said 1923 is still true: "Until this state of affairs is remedi and the treatment of both acute and latent gonorrh in the female is taken up seriously by the profession, incidence, which is already large, will undoubte increase, and the gonococcus will continue to be resp sible for a large proportion (some put it as high as 50 of the tubo-ovarian and other pelvic conditions wh are seen in gynæcological wards, and for a great amo of the chronic ill health from which so many wo suffer."

The discovery that penicillin is remarkably effect in producing clinical cure of gonorrhœa marks an adva in treatment, but there are dangers in the wave of ov optimism that has followed the wide publicity given enthusiastic reports. General release of penicillin the market may lead to its indiscriminate use and g rise to a sense of false security, with disastrous c sequences. Some patients are inclined to look on gon rhœa like a mere cold, to be thrown off in no time the aid of a single injection. A large percentage those treated with penicillin do not complete the of observation and tests of cure.

As examples of the optimistic view one may Marshall (1945):

> "With a dosage of 100,000 units and upwards, in four five separated injections

rapid clinical cure of 90% of cases of uncomplicated and ulphonamide-resistant gonorrhœa can be confidently xpected.”

Ministry of Health circular says:

hus a single injection of 200,000 units (penicillin in oil) as been sufficient to effect apparent cure in over 90% f cases of acute gonorrhœa.”

illcox (1946) records that, during a recent visit to nited States, “It was an often-expressed view that rrhœa was beaten: and, though there were isolated s urging maintained caution, there was an increas- endency to relax the severity of the tests of cure in isease.”

cording to Willcox, J. F. Mahoney gave 200,000 s of an aqueous solution of penicillin in five doses to patients; and, apart from instructing the patient btain a blood-test in three months' time, there no tests of cure.

assessing cure of gonorrhœa in females there is e evidence of caution, for general examinations have conducted once a month for three months in some tres. Yet, in a very large clinic in Chicago, cultures smears after three days constituted the only follow-up ses of clinical cure, apart from monthly blood-tests three months.

ll these facts indicate an attitude of mind which must regarded as dangerous, having regard to the past ry of this perplexing and insidious disease. Methods treatment have changed quickly, but the character a disease changes slowly, and there is no reason yet ppose that gonorrhœa has lost its predilection ections latency.

he example of the sulphonamides is still before us, it may be well to learn caution from consideration the recent past.

okkinis (1939) claimed that 77% of cases of gonorrhœa ated with sulphonamides in the second week of the ction were cured, with a late relapse-rate of 9%. (1939) claimed that with sulphapyridine in over of 300 cases signs and symptoms had disappeared in than three weeks. Laird (1942), using various emes of dosage in 764 cases, obtained very similar lts with sulphonamides, with a success in each series ing from 81 to 91%.

ater came a very different report. Campbell (1944) ted out that in Sicily and Italy, from the very first, honamides were relatively ineffective. Whereas, until time, 65–70% of patients had recovered completely hatever initial course of sulphapyridine or sulpha- zole had been given, the percentage had dropped at to considerably less than 20. Under the very conditions, and with the employment of an increased ge of drugs, such as sulphathiazole and the small able supply of sulphadiazine, success resulted in not than 45%. The remaining 55% had continued to gonococci after treatment, and these persisted for a long time.

rness (1944) attributed this state of affairs to g resistance.” He thought that three potential rs were involved—faulty dosage; indiscretions of patient: and previous administration of the drug.

t that time I urged that the indiscriminate use of honamides for minor ailments was likely to lead cline in the efficiency of these drugs, and I recorded pression that there was an increase in the number gonococcal carriers.” It has seemed recently that y may be repeating itself, since my results with illin in gonorrhœa were less favourable, in female ents at any rate.

t has long been known that the assessment of the lts of treatment of gonorrhœa in the female presents difficulties; and the experienced clinician demands onsiderable period of observation and many tests re reaching a decision about cure.

In view of these considerations I have analysed 39 consecutive cases of gonorrhœa in the female which have recently been under observation at the L.C.C. (Whitechapel) Clinic. The table gives the results of this analysis, and it will be seen that in no less than 18 of the 39 cases the results were unsatisfactory, and that in a further

‖ Developed gonococcal bartholinitis after penicillin.

thus there is a round opening behind the knee. Two slots, 1 in. × $^1/_4$ in., are cut one on each side, $^1/_4$ in. from the lateral margin and 1 in. from the proximal end.

The thigh- and calf-pieces are joined at an angle of 15°, so that the foot-piece and the upper end of the thigh-piece both rested on the bed, with the contained limb in a comfortable position.

Calf-piece.—Unless it is for a short splint a half-circle is cut in the proximal edge, corresponding with that in the thigh-piece. Two slots are cut in the upper end similar to those in the thigh-piece, and two slots in the lower end set obliquely at 45° across the corners. The lower edge, and for a short splint the upper also, is moulded outwards to prevent chafing.

Foot-piece.—Shaped roughly like the sole of a boot. Two slots, 1 in. × $^1/_4$ in., cut one on each side, halfway along the length and $^1/_4$ in. from the edges.

Connecting L-piece.—Width $^1/_2$–1 in. according to size of splint. The straight portions of the L are riveted to the calf-piece for half its length and to the foot-piece for the whole of its length. There is a wide U-bend, 1$^1/_2$–3 in. wide and deep, at the angle of the L, to accommodate the heel. A $^3/_8$ in. screw is riveted into the curve of the U to fit into the slot in the cross-bar.

Cross-bar.—For a single splint this consists of a straight strip 2–3 × 6–8 in. A hole is drilled in the centre to take the screw mentioned above. The bar is turned at right angles along its edges for greater strength.

The cross-bar for a double splint is curved, the curve being the quadrant of a circle of radius equal to the length of the lower limb. Slots are cut in the bar to allow variation in the degree of abduction.

MEASUREMENTS

The measurements supplied to the instrument-maker are body measurements, from which he works out the splint measurements as described below. The calculations are accurate for average-sized splints, and certain obvious allowances must be made for very large or small splints. The measurements of width for the thigh- and calf-pieces are on the flat before bending into an arc slightly wider than a semicircle.

Great trochanter to external condyle of knee	Subtract 3 in.	= Length of outer edge of thigh-piece
External condyle of knee to sole of foot	Subtract 2 in.	= Length of calf-piece for long splint
	Subtract 4 in.	= Length of calf-piece for short splint
Girth of thigh at groin..	Divide by 2	= Breadth of thigh-piece at upper end
Girth at knee	Divide by 2	= Breadth of thigh-piece at lower end, and breadth of calf-piece at upper end
Girth above malleoli ..	Divide by 2	= Breadth of calf-piece at lower end
Length of foot, heel to great toe	Add 2 in.	= Length of foot-piece
Breadth of forefoot ..	Add $^1/_2$ in.	= Breadth of foot-piece at widest point
Breadth of heel ..	Add $^1/_2$ in.	= Breadth offoo t-piece at heel

Upper-limb abduction splint

This was designed for ease of manufacture and comfort in wearing both when in bed or when ambulatory. The framework is made from duralumin, mild steel, or brass rod of a gauge of $^5/_{16}$ in. for large splints and proportionately smaller gauge for small splints.

The frame is covered throughout with leather and padded in its vertical component and at the waist. A canvas bodice with shoulder-straps is sewn on to the posterior part of the chest-piece and fastened with two buckles and straps. The shoulder-straps are adjustable with buckles sewn on the front of the bodice. The bodice is cut away under the axilla to prevent chafing.

The width of the splint averages 3 in. for a medium-sized child aged 3–5 years, and 4–5 in. for adults. The width is the same from the hand to the crest of the ilium, where the splint broadens out to encompass nearly half the girth at the waist. The waist-piece is curved in two dimensions to fit round the waist and follow the curve of the crest of the ilium. It is about 2 in. wide and is well padded. The hand-piece is about 1 in. wider and is padded to give a comfortable grip.

MEASUREMENTS

Measurements are given for the frame only, since it found that measurements for the bodice were best take the tailor who could then ensure a perfect fit.

From posterior axillary fold, or middle of the head of the humerus, to the tip of the olecranon	Add $^1/_4$ in.	= Length of outer or terior rod of arm tion
From axilla to crest of ilium	Add $^1/_2$ in.	= Length of vertical and length of oute of forearm portio
Half the girth at waist ..	Divide by 2	= Length of waist-piec

Bradford frame

The metal frame (fig. 4) is made from mild steel tu with an internal diameter of $^1/_2$–$^3/_4$ in. and painted or spr with aluminium paint. It is rectangular, with rou corners.

The frame is supported on two wooden blocks 4 in. and hollowed out to reduce weight. The frame fits grooves in the blocks and is held down with metal st The frames are covered by two canvas slings, laced un neath; a gap of 4–6 in. is allowed between the two canv to prevent soiling and to allow the use of a bedpan.

Where double gutter splints are required the lower can can be dispensed with, a wooden bar being fixed across frame to support the splints under the thigh-pieces (fig.

MEASUREMENTS

From vertex to sole of heel..	Add 4 in.	= Length of frame
From vertex to coccyx ..	Add 2 in.	= Length of upper can
Breadth between posterior axillary folds (or middle of the heads of the humeri)		= Width of frame, ov or external meas ment
Length of lower canvas ..		= Length of frame, length of upper can less 4–6 in.

PENICILLIN FOR GONORRHŒA IN THE FEMALE

W. NEVILLE MASCALL
M.R.C.S.
DIRECTOR, L.C.C. (ENDELL STREET) CLINIC

IN the past gonorrhœa in the female has seld received the attention which it deserves from the medi profession; and in recent years the introduction of n and effective remedies has detracted from an inter which was never strong, for there is a tendency to assu that these infections are easily cured and are not acco panied by serious after-effects. There is still no gen recognition of the fact that this is a most damag complaint, with far-reaching consequences, unless trea skilfully in its early stages. What Thomson said 1923 is still true: "Until this state of affairs is remedi and the treatment of both acute and latent gonorrh in the female is taken up seriously by the profession, incidence, which is already large, will undoubte increase, and the gonococcus will continue to be resp sible for a large proportion (some put it as high as 50 of the tubo-ovarian and other pelvic conditions wh are seen in gynæcological wards, and for a great amo of the chronic ill health from which so many wo suffer."

The discovery that penicillin is remarkably effect in producing clinical cure of gonorrhœa marks an adva in treatment, but there are dangers in the wave of o optimism that has followed the wide publicity given enthusiastic reports. General release of penicillin the market may lead to its indiscriminate use and g rise to a sense of false security, with disastrous c sequences. Some patients are inclined to look on gon rhœa like a mere cold, to be thrown off in no time the aid of a single injection. A large percentage those treated with penicillin do not complete the co of observation and tests of cure.

As examples of the optimistic view one may qu Marshall (1945):

> "With a dosage of 100,000 units and upwards, in four five separated injections over eight to twelve ho

a rapid clinical cure of 90% of cases of uncomplicated and sulphonamide-resistant gonorrhœa can be confidently expected."

A Ministry of Health circular says :

> Thus a single injection of 200,000 units (penicillin in oil) has been sufficient to effect apparent cure in over 90% of cases of acute gonorrhœa."

Willcox (1946) records that, during a recent visit to United States, "It was an often-expressed view that orrhœa was beaten ; and, though there were isolated ces urging maintained caution, there was an increas- tendency to relax the severity of the tests of cure in disease."

According to Willcox, J. F. Mahoney gave 200,000 its of an aqueous solution of penicillin in five doses to le patients ; and, apart from instructing the patient obtain a blood-test in three months' time, there re no tests of cure.

In assessing cure of gonorrhœa in females there is re evidence of caution, for general examinations have n conducted once a month for three months in some ntres. Yet, in a very large clinic in Chicago, cultures nd smears after three days constituted the only follow-up cases of clinical cure, apart from monthly blood-tests r three months.

All these facts indicate an attitude of mind which must e regarded as dangerous, having regard to the past istory of this perplexing and insidious disease. Methods f treatment have changed quickly, but the character a disease changes slowly, and there is no reason yet suppose that gonorrhœa has lost its predilection r infectious latency.

The example of the sulphonamides is still before us, d it may be well to learn caution from consideration the recent past.

Cokkinis (1939) claimed that 77% of cases of gonorrhœa eated with sulphonamides in the second week of the ection were cured, with a late relapse-rate of 9%. (1939) claimed that with sulphapyridine in over % of 300 cases signs and symptoms had disappeared in than three weeks. Laird (1942), using various hemes of dosage in 764 cases, obtained very similar ults with sulphonamides, with a success in each series ging from 81 to 91%.

Later came a very different report. Campbell (1944) inted out that in Sicily and Italy, from the very first, phonamides were relatively ineffective. Whereas, until t time, 65–70% of patients had recovered completely whatever initial course of sulphapyridine or sulpha- zole had been given, the percentage had dropped at e to considerably less than 20. Under the very conditions, and with the employment of an increased age of drugs, such as sulphathiazole and the small lable supply of sulphadiazine, success resulted in not than 45%. The remaining 55% had continued to gonococci after treatment, and these persisted for a long time.

arkness (1944) attributed this state of affairs to ug resistance." He thought that three potential ors were involved—faulty dosage ; indiscretions of patient ; and previous administration of the drug.

t that time I urged that the indiscriminate use of honamides for minor ailments was likely to lead ecline in the efficiency of these drugs, and I recorded mpression that there was an increase in the number gonococcal carriers." It has seemed recently that ory may be repeating itself, since my results with illin in gonorrhœa were less favourable, in female ents at any rate.

has long been known that the assessment of the s of treatment of gonorrhœa in the female presents difficulties ; and the experienced clinician demands nsiderable period of observation and many tests re reaching a decision about cure.

‖ Developed gonococcal bartholinitis after penicillin.

16 cases there was evidence of probable failure. In the table the cases are grouped according to the scheme of treatment used.

ADMINISTRATION OF PENICILLIN

Four different schemes of dosage were used:

(1) Multiple injections of an aqueous solution—five doses of 30,000 units two-hourly, totalling 150,000 units, or five doses of 60,000 units two-hourly, totalling 300,000 units.
(2) Single injection of 200,000 units in aqueous solution.
(3) Single injection of 150,000 or 200,000 units in arachis oil and beeswax.
(4) Inpatients, with syphilis also, were given sixty injections, each of 40,000 units at three-hourly intervals, totalling 2,400,000 units.

All penicillin was kept in the refrigerator. The aqueous solution was made up fresh for each injection. The syringes used were sterilised by boiling, and no antiseptics were employed.

TESTS USED

(1) Smears were taken from the urethra and cervical canal and stained by a modification of Gram's stain. In the table certain smears are marked +; these specimens were reported as doubtful, which implies gram-negative *extracellular* diplococci, in all other respects morphologically *indistinguishable from gonococci.*
(2) For cultures, material from the urethra, the posterior fornix of the vagina, and the cervical canal was inoculated onto Price's serum agar (pH 7·5–7·6). The slopes used for the urethra and cervical canal and the plate used for the posterior fornix of the vagina were warmed to 37° C in an incubator before use and were immediately returned to the incubator after inoculation. This technique is essential if the gonococci are to be grown successfully.

CASE ANALYSIS

Of the 39 patients 12 had gonorrhœa and syphilis and were admitted to hospital, where they received 2,400,000 units of penicillin in sixty injections of 40,000 units at three-hourly intervals. Of these 12 patients 5 showed signs of active gonorrhœa, with positive tests, after discharge from hospital. One of these patients received a further injection of 200,000 units of penicillin in arachis oil and beeswax, and still showed extracellular gram-negative diplococci.

The series included 3 children with vulvovaginitis. In our experience this type of case has not responded well to penicillin, and Dr. F. R. Curtis has reported (in a personal communication) similar experience in treating children in Germany. In this respect case 17 is of much interest. This was a child, aged 4 years, who first received 16 g. of sulphathiazole, with improvement, followed by a clinical and bacteriological relapse. Penicillin 150,000 units was then given in divided dosage; tests were again positive, and this was followed by 300,000 units of penicillin in divided dosage. Tests were still positive, and the child was given a further single injection of 250,000 units in arachis oil and beeswax. Relapse took place again; so a course of sulphadiazine was given, with subsequent negative findings. All other members of the family were examined and found to be free from infection.

The other 2 cases of vulvovaginitis cleared with sulphonamides after unsuccessful treatment with penicillin. It is reasonable to suppose that such children become "gonococcal carriers," for there is often very little clinical evidence of the infection.

Case 30 is also of special interest, inasmuch as this patient developed a Bartholin abscess, from the pus of which gonococci were cultured, seven days after the administration of 200,000 units of penicillin in arachis

RELAPSE OR REINFECTION

The problem of whether a case is one of true re
or of reinfection is commonly insoluble. Often this i
question of the patient's word, and there are no
standards of reliability.

In every case in this series the patient was closely c
examined about the possibility of reinfection. I inte
to exclude any case in which there was the least sh
of doubt regarding reinfection; but the occasion did
arise.

Several of the patients with double infection
examined on the day of leaving hospital, or next day.

COMMENT

Reports have been published claiming 90% or more
successes in removing gonococci from the secretions
in resolving the clinical signs of gonorrhœa
present small series of cases does not confirm thes
ings and, in the mind of the careful clinician, wi
even greater doubt about the bacteriological c
patients treated in this way.

Now that penicillin is available generally to all
tioners, a word of warning may be given agai
indiscriminate use. It will be unfortunate if p
with vaginal discharge are treated with penicillin w
proper investigation, as they sometimes have bee
the sulphonamides. It should be remembered
Trichomonas vaginalis, monilia yeasts, and some
organisms which give rise to an abnormal vagina
do not respond to penicillin. The gonococcus ma
be present in these cases, and this fact may be ob
by treatment without preliminary diagnosis.

Three points seem to be essential for successful pe
therapy: a correct diagnosis, an adequate dos
penicillin, and a prolonged period of observation
treatment. Far from any relaxation of the tests o
for gonorrhœa, more care in observation and tests
treatment should be the rule. This should be sim
by the fact that it is important to keep these pa
who have been treated with penicillin, under ob
tion for at least six months, to be certain that a coe
syphilitic infection has not been suppressed b
administration of the penicillin.

It is possible that our present dosage of penicill
gonorrhœa is inadequate, and that it is only suf
to induce latency in some cases. However, the ca
which 2,400,000 units of penicillin were given wi
success suggest the possibility that some stra
gonococci are naturally resistant or have acq
resistance.

Vulvovaginitis has been always a difficult con
to treat, and it does not appear that the ideal met
treatment has been discovered yet.

SUMMARY

Of 39 females with gonorrhœa treated with peni
in amounts generally considered more than ade
24 did not respond to the treatment.

Tests showed positive or doubtful findings in
smears or cultures, or both, at a period of not less
seven days after the start of treatment.

In 3 patients tests were still positive after treat
with increased dosage of penicillin.

I wish to thank Mr. Ambrose King, F.R.C.S., director
L.C.C. (Whitechapel) Clinic, for his helpful coöperation.

EPIDEMIC KERATO-CONJUNCTIVITIS IN BENGAL

THE INCUBATION PERIOD

B. THORNE THORNE
M.B. Camb., M.R.C.P., D.O. Oxfd
ASSISTANT SURGEON, SUSSEX EYE HOSPITAL; FORMERLY OPHTHALMIC SPECIALIST, R.A.F.V.R.

IN September, 1944, and in September, 1945, outbreaks of epidemic kerato-conjunctivitis occurred among Service personnel in the Calcutta area. In the 1944 series 10 cases were seen and treated at a Royal Air Force centre. One was severe and developed a tenonitis, and another case was complicated by iridocyclitis. This account deals with the series of 17 cases seen in September, 1945, at the same R.A.F. centre (see table). The patients were airmen who had all been playing football on muddy grounds in the Calcutta area, 8 patients came from one unit, 7 of whom played football on a very waterlogged ground on the same day, and for some of the players it was the only game in which they had recently taken part. Therefore the date of infection could be accurately determined, as could the date of onset of symptoms, and thus the incubation period. A considerable number of cases also occurred among Army personnel in the same area and at the same time, and these were treated at the Army hospital.

Symptoms.—The disease was characterised by an acute onset of pain and lacrimation in one eye, the usual story being that the man woke up in the morning with these symptoms, having retired to bed the previous night perfectly well. Only in 2 of the 17 cases had both eyes been involved. Examination showed intense conjunctival injection, swelling of the lids—mostly the outer two-thirds—and some chemosis of the lower palpebral conjunctiva. Lacrimation and photophobia were well marked, but a purulent discharge was rare. The keratitis was usually of the superficial punctate type, more often affecting the periphery, but sometimes it was generalised. In a few of the cases the subepithelial layers were involved, and in one the corneal infiltration was of the disciform variety. Corneal sensation was much diminished in all cases. Keratic precipitates were present in 3 cases (four eyes). Preauricular adenitis was a prominent feature and was present in all cases, and in some the submaxillary glands were involved. The glands were always painful and tender at the onset of the disease. The interval between the onset of symptoms and the presence of corneal changes was short, under seven days in all cases, and in many the keratitis was well marked when first seen only a day or two after the onset. History of trauma to the eye was obtained in only 2 cases.

Incubation Period.—This was between twelve and seventeen days, and in most cases this could be determined with accuracy. This period is longer than that suggested by Feigenbaum et al. (1945) and Sanders (1942) who put it at four or five days.

Infecting Agent.—This is thought to be a filtrable virus, and all conjunctival swabs when taken in these cases were negative. In Bengal, by September the monsoon season is more than half over, and the ground is soft and at times under water. The virus is thought to be present in the soil and to be transferred readily to the eyes of footballers playing on muddy grounds. The disease has been recognised in India for many years, particularly in the coastal districts (Kirkpatrick 1920).

Treatment.—It was soon realised that, apart from instillation of atropine and the wearing of dark glasses, other local treatment to the eye appeared to do more harm than good, except that the more severe cases were given a course of short-wave diathermy, and the impression gained was that it was of benefit. All patients were also given vitamins B and C by mouth.

Progress.—This varied with the severity of the case, and the period from the onset of symptoms to the time when the eye was quiet was from six days to three weeks. Visual acuity returned to normal or just below normal after a further period of three or four weeks, but corneal sensation took longer to recover.

SUMMARY

An outbreak of epidemic kerato-conjunctivitis in the Calcutta area is described.

The incubation period could be accurately determined in most cases, and was between twelve and seventeen days.

This is longer than that previously described.

I wish to thank the Director-General of Medical Services, R.A.F., for permission to publish this report.

ry coöperative. Samples of twenty-four-hour urine re *collected daily, and fæces were collected twice* ekly for about six months. The urine was measured d examined for nicotinamide methochloride by the ethod of Coulson, Ellinger, and Holden.[13] The fæces re cooled in a refrigerator to about 2° C immediately ter having been passed. A sample was weighed out ualling about 25 mg. dry weight, and a suspension as made in 5 ml. of sterile peptone water and filtered rough a sterile paper filter. This filtrate was diluted : 40, and further serial dilutions of 1 : 10 were made in ptone water. In case 1 examinations were carried out ith the dilutions to determine quantity and types of aerobes growing aerobically and anaerobically on solid edia, and of gas- and acid-producers growing in litmus-ctose broth, types of anaerobes and anaerobic spore-earers growing in Brewer's medium and of acid-resistant erobes and anaerobes in acetic-acid-glucose broth; mears were examined from the original suspensions. n case 2 no solid media have been used, but in addition e total of living aerobic and anaerobic organisms was amined by titration, and aerobic and anaerobic spore-earers and acid-resisters were quantitatively estimated. n both cases the patients were given ambamide 1·5 g. three-hourly (12 g./day) for six days. The results are shown in table I.

The results show that during the ambamide dosing period there was an increase in the number of coliform bacteria growing on solid media in case 1; of bacteria growing in Brewer's medium and of total living organisms under aerobic and anaerobic conditions in case 2; and of gas- and acid-producers in both cases. The methods used up to now have not given satisfactory information about the total number of anaerobes, but anaerobic spore-bearers and anaerobic acid-resisters showed in case 2 a temporary reduction in numbers. The gas- and acid-producers which increased in number were three types of coliform bacteria, and the organisms growing in Brewer's medium were mainly diplo- and strepto-cocci. The anaerobic spore-bearers were mainly large gram-positive rods in pairs or chains; and the anaerobic acid-resisters gram-positive rods which produced acid and clots in milk.

5	741·0	414·3	418·7	824·0	723·0	587·0	689·7	875·0
6	1104·0	334·0	594·2	1792·0	2120·0	772·0	774·0	Lost

After the treatment with ambamide had been stopped, the bacteria and the output of nicotinamide methochloride returned slowly to their previous levels, except the acid-resisting anaerobes, which rose to a considerably higher level.

EXPERIMENTAL RESULTS IN RATS

In another experiment the effect of ambamide on the output of nicotinamide methochloride in rats was examined, but the bacterial content of the fæces was not examined. Adult rats were put on a mixed diet, and the daily urinary output of nicotinamide methochloride was estimated before, during, and after administration of ambamide. Each rat received ambamide 2·25 g. a day in its food for four days. Four of the rats had a low output of less than 100 µg., and two a high output of more than 500 µg., of nicotinamide methochloride before being given ambamide. The results are shown in table II, which shows, after a temporary depression in some instances, a considerable rise in output of nicotinamide methochloride in all but one rat (no. 5) during and immediately after the period of dosing with ambamide.

DISCUSSION

The chief results of the experiments are the increased output of nicotinamide methochloride and the increase of the coliform intestinal flora during the period of dosing with ambamide. These coliform bacteria can produce nicotinamide in vitro.[14] Whether this increase of the coliform flora is due to a direct stimulating effect of ambamide or to a destruction of anaerobes enabling increase of the coliforms cannot be concluded from the present experiments and must be examined further. No information can be obtained about the total numbers of anaerobes with the methods used so far, since most of the aerobes are facultative anaerobes and appear also in the anaerobic cultures. The increased output of nicotinamide methochloride may be due to the increase of nicotinamide-producing coliforms alone or to the simultaneous decrease in nicotinamide-consuming or nicotinamide-destroying anaerobes.

1[illegible]. Coulson, R. A., Ellinger, P., Holden, M. *Biochem. J.* 1944, 38, 150.

14. Ellinger, P., Kader, M. M. 1945, unpublished.

The complete experiments will be reported in detail later. They show distinctly that the ingestion of ambamide increases simultaneously the numbers of coliform bacteria, which are known to synthesise and release nicotinamide, and the elimination of nicotinamide methochloride in the urine. This is further evidence for the conclusion that human nicotinamide requirements are partly covered by the release of this compound by the intestinal flora.

We are deeply indebted to the late Dr. H. Schütze for advice and supervision of the bacteriological work.

Our thanks are due to Dr. G. A. Caldwell for permission to carry out the investigation at West Park Hospital, Epsom; Drs. S. W. Hardwick and W. P. Berrington for the clinical care of the subjects; the nursing staff of West Park Hospital for the careful collection of the specimens; Miss D. Garner for technical assistance; and Messrs. R. F. Reed Ltd., of Barking, for ambamide tablets. The work was carried out with a grant from the Medical Research Council (personal grant for A. E. and grant for technical assistance and expenses).

Addendum.—Since this paper was submitted two more people have been treated with ambamide and the fæcal bacteria and the urinary output of nicotinamide methochloride examined. In one person conditions were similar to those reported. In the other the rise in coli and nicotinamide methochloride occurred only after a temporary depression similar to that observed in rats.

Reviews of Books

Physics for the Anæsthetist

R. R. MACINTOSH, M.A., D.M. Oxfd, F.R.C.S.E., D.A., Nuffield professor of anæsthetics, University of Oxford; WILLIAM W. MUSHIN, M.A., M.B. Lond., D.A., first assistant in the department. Oxford: Blackwell Scientific Publications. Pp. 235. 30*s.*

KNOWLEDGE of the basic sciences, clinical acumen, and technical skill are the requisites of the trained anæsthetist. Extensive theoretical knowledge without the power of clinical application is of little value. Many anæsthetists, however, are technically very dexterous and yet do not know or are incurious about the meaning of everyday observations. The authors of this book have picked out the relevant physical laws and fully expounded their application to anæsthetic practice. Among other things, they discuss the structure of matter and the properties of gases and vapours; why cylinders of nitrous oxide freeze up; how the modern anæsthetic apparatus has developed; the working principles of the various meters for measuring gases; the causes of heat-loss through the respiratory tract; atmospheric pressure and the results of increased and decreased pressure; gas-cylinder pressures; the importance of turbulence and resistance in the design and use of anæsthetic equipment; the rationale for the use of helium-oxygen mixtures; aero-embolism and intravenous infusions; and the effects on the circulatory, renal, and respiratory functions of osmosis, diffusion, and filtration. Useful tables of physical data and a short biographical study are included, and the work is fully and admirably illustrated by Miss M. McLarty.

Physics for the Anæsthetist fills a want long felt by anæsthetists both old and young. It may also be recommended to the preclinical student, who will find his first year's work far more interesting if he appreciates the application it will have later.

Medical Uses of Soap

Editor: MORRIS FISHBEIN, M.D. London: J. B. Lippincott. Pp. 182. 18*s.*

THIS instructive volume, dealing with soap and many of its effects upon the skin, has been compiled by a group of experts. The chemistry of soap and its usual method of manufacture is clearly and briefly explained, and a slight knowledge of the different varieti
certainly useful to those who may have to deal with
of the ill effects produced by soap. The action of
in cleansing is, as is well known, brought about by
removal of the dirt-impregnated horny layer,
being more efficient for this purpose than acid.
stressed, however, that too thorough removal
natural covering of the skin tends to deprive it of
of its essential protectiveness. To a certain extent
soap is germicidal—but unfortunately only
germicidal for staphylococci. However thor
scrubbing with soap and water may be carried
bacterial flora cannot be completely removed fro
skin; but in the prevention of syphilis the imm
use of soap and water is probably far more valuabl
many of the other prophylactic measures freq
advised.

In cases of dermatitis due to soap, direct dam
the skin is the most important factor, but softening
skin by the alkaline action of soap may often prepa
way for secondary infections. In treating disea
the skin the question whether to withhold soap
water or not is sometimes difficult to answer, an
authors discuss the problem fairly fully. Ther
useful sections on the use of soap in industry, ar
shampooing and shaving, and the use of sulpho
oils as cleansers is also considered.

Modern Treatment Year Book 1946

Editor: Sir CECIL WAKELEY, D.SC., F.R.C.S.,
surgeon, King's College Hospital, London. Lo
Medical Press and Circular. Pp. 326. 15*s.*

THIS latest volume, the twelfth in the series,
true to type—a miscellany from which the practi
will glean many a useful tip. It is refreshing in these
of "scientific" medicine to find an exposition of h
cure warts in children by "charming," and the s
on the treatment of migraine is wonderfully compr
sive. Post-war difficulties are probably responsibl
the rather large number of misprints. This is not a
reference book, but its 37 chapters are a useful guid
the general practitioner to the intricacies of m
medicine.

Die Grundlagen unserer Ernährung und un Stoffwechsels

(5th ed.) EMIL ABDERHALDEN, professor in the Univ
of Zurich. *Berne: Huber. Pp. 202. Sw. fr. 8.50.*

THE first edition of this book appeared during the
world war and became well known in Germany i
years which followed when nutrition was upperm
many German minds. Abderhalden kept the book
date, in spite of his other activities, all the time he
the chair at Halle. Whatever his political views,
have been, the close of the second world war foun
still at Halle, but he has now accepted a chair at Z
and there, in what must be his old age, he has pre
a fifth edition of his little book.

It is not often easy for a man with an encyclo
mind to write an elementary book; but if he can
himself to do so the result may be very good, and has
so in this instance. This book is simply written, b
the whole still up to date, showing a balance lacki
many English and American books of similar ca
There are good chapters on the parts played by plant
animals in the economy of nature, the various
stuffs, water, minerals and vitamins, digestion
cellular metabolism, and quantitative requirem
(though this chapter does not reach the standard o
others). Protein requirements should nowaday
considered in terms of amino-acid requirements;
more might have been said about the value of plant
animal proteins in human nutrition: in Germany t
there is a tendency to believe that only animal pr
has any virtue at all. The addendum on the
question is rather weak: the author sets himself f
on the fence—which is quite permissible if he find
seat comfortable—but the only evidence discussed
to do with the amount of B_1 in flours of various extrac
Nevertheless there are some delightful little points
here and there in this book, and it may be recomme
safely to anyone who wants a good introduction to
subject of nutrition.

ANAHÆMIN B.D.H.

THE ERYTHROPOIETIC FRACTION OF LIVER

Described by Dakin and West

The principal indication for Anahæmin B.D.H. is the treatment of pernicious anæmia. It is highly effective also in preventing the onset of subacute combined degeneration of the cord as well as in correcting all the remediable symptoms of this syndrome if it has become established.

A third important application of Anahæmin B.D.H. is for the treatment of debility, diminished vigour and undue 'fatiguability'.

In all these indications Anahæmin B.D.H. is unsurpassed by the less highly refined liver products, in efficacy, volume and frequency of dosage and in economy.

London Medical Exhibition—members of the medical profession will be welcome at the B.D.H. Stand No. 140

Potent penicillin for 'single dose' success

Early injection of sufficiently potent penicillin prc duces outstanding regression of infection and ma also save the need for frequent doses. With one o two doses of 200,000 to 500,000 units of Penicilli *Glaxo* many cases of infection of the hand, for example clear up completely. Pain is quickly relieved; anc even should pus form, localisation takes place avoiding spread, anc on evacuation healing is markedly hastened.

To shorten the total duration of disability, therefore, there is good reasor to use Penicillin *Glaxo* whose potency and purity is reflected by it content of not less than 1,400 units per mgm.—a routine achievement

Yes or No?

THE enactment of the National Health Service Bill st week obliges the profession to reconsider its proisions and decide on a course of action The Act, as ; now emerges, is a much less revolutionary measure han it would have been if the original suggestions Mr. ERNEST BROWN had been translated into law. t derives much more from the long discussions etween the profession and the Ministry of Health han it does from any doctrinaire ideas of the present Minister's political party It is in fact much less cialistic than was predicted a year ago. Inevitably ny measure making State provision over a widening field must conflict at many points with established custom The question whether the advantages of a service planned on these lines outweigh the disadvantages is one that each one of us must answer individually in the light of his own convictions and circumstances Fortunately we are to have an early opportunity of recording our opinion. The council of the British Medical Association has wisely judged that the time has come to ascertain the wishes of the profession about the next step.

The Act now passed does not attempt to set out a detailed workable scheme ready to be put into action on the appointed day. It is in fact only a framework—an enabling Act, allowing the Minister to make gulations whereby a service can be brought into ing. In drafting these regulations, Mr. BEVAN will undoubtedly invite the aid of the profession: indeed he has indicated more than once that though the responsibility for the policies shaping the Act itself was one which Parliament could not and would not abrogate, there would afterwards be ample scope for consultation and expert collaboration in working out its translation into action Hence we may confidently expect an invitation to participate in this next phase. Are we to accept this invitation? It is this question that we are each being asked in the plebiscite now being taken by the B.M.A. What then are the implications, and what would be the consequences of a positive or negative answer?

In the first place we may note that it is not necessary o say now whether the profession should eventually participate in the service. The question is whether we ant our negotiators to take a share in devising the regulations to be made under the Act On this issue opinion will of course be divided. One group will hold that it is possible, within the framework of the Act, to draft regulations producing a service in which they could be content to work and able to work well In this hope they will naturally want to see the wishes and the experience of the profession given the maximum consideration during this next phase, and they will answer "Yes" to the B M.A.'s question. In so doing they will in no way commit themselves to joining the service later; for if their hopes are unfulfilled they will still be able to say that, on seeing the Act in its entirety, they cannot join the service. Those in the other group, who believe that no regulations, however favourable, could make service under the Act acceptable, will obviously not wish the profession to become involved in any further negotiations, and will answer "No" But there is much more finality about this negative answer, which can be given only by those who are firmly resolved to have nothing to do with the new service, however it may turn out. A negative answer from the majority will not prevent Mr. BEVAN from making his regulations, advised only by the officials of his Ministry: but it will remove the profession's main opportunity to improve the service. It is difficult therefore to see how the answer "No" could legitimately or logically be reconciled with reluctant acceptance at the latter end

Yet there will be many who will wish—at whatever sacrifice—to answer "No," because they will feel that in so doing they are taking their one chance to protest against the Act. When the Bill first appeared we all found clauses that struck hard at familiar ways and customs. Many of us hoped to see these clauses disappear from the Act; but, though most are modified, all remain. What we have to ask ourselves is whether the modifications sufficiently mitigate the hardship of the original proposals. In many cases we believe they do. For instance, under the original provisions the only doctors with access to private beds in a hospital would have been the consultants working inside the service in that hospital; but now access is offered to all practitioners (not consultants only) associated in a paid or an honorary capacity with the hospital—an enlargement that alters the whole concept. Modifications made in the powers of hospital management committees, and concessions over hospital endowments, have gone far to satisfy the voluntary hospitals. As regards the general practitioner's lot—and this after all is what most closely affects the greatest number of doctors—opposition was aroused chiefly by (1) the abolition of sale and purchase of practices and the penal clauses inserted in the Bill to guard against concealed sale of goodwill, (2) the limitation of the doctor's choice of an area in which to practise, and (3) the payment of a basic salary. None of these provisions has disappeared, but each has undergone modification in the Act, or in definite undertakings given by the Minister. Parliament has insisted on abolishing the sale of practices, even though this has meant voting a considerable sum of money to compensate the owners of practice goodwill; but it has so modified the penal clauses as to protect bona-fide transactions, and it has made it clear that the local doctors, including those remaining in the practice, will be able to influence the choice of successors to vacancies. It has also agreed that full consideration shall be given to the wish of a doctor to have a son or other relation join or succeed him in practice, and has thus materially reduced the objections to the powers of "negative direction." The Minister resisted the House of Lords' amendment which would have made payment by capitation the sole ordinary method of remuneration, and basic salaries therefore remain a probable part of the practitioner's emoluments; but as they are not mentioned in the Act their amount and even their universal application could still be matters for negotiation. Also, we have the Minister's assurance that the capitation fees and not the basic salary will be the major element of remuneration. Such modifications as these are not very great, but they certainly suggest that the Government wants to produce a practicable scheme. The passage of the Bill through the Lords was marked by a new atmosphere of constructive coöperation, which would improve results if continued.

Such arguments will give cold comfort to many. Thinking in terms of pre-war conflict rather than post-war reconstruction, they will regard them as appeasement, and will argue that there must be no compromise so long as any part of the Act is capable of being used or developed in such a way as to restrict clinical freedom or alter the relationship of trust between us and our patients. But those who take this view will do well to remember that any Act which sets out to assure a service to the people must contain some sanction for governmental use if unforeseen circumstances should threaten a breakdown of the service. Such a sanction was written into the National Health Insurance Act: it gave the Minister power to suspend N.H.I. regulations in a particular area, and institute there any form of service (not excluding a whole-time salaried service) that he thought appropriate. Yet during the last thirty years this power has only once been used, and the profession has been hardly aware of its existence. The opportunities that the new Act provides for professional participation in administration at all levels seem sufficient to ensure that no unjust use will be made in the future of the sanctions Parliament has now thought appropriate.

In this article we have concentrated on the immediate consequences of refusing further negotiations, and have said nothing about the more remote consequences that might be expected from a refusal by the profession to work the Act. We have tried to make it clear, however, that only an affirmative reply will give us the opportunity of seeing the whole structure shaped and completed under the most favourable conditions. Those who reject this opportunity will assume a heavy responsibility.

The Artificial Kidney

THE cause of death in acute uræmia has not yet been discovered but there is little doubt that the accumulation of diffusible metabolic products plays some part in it. If such products could be removed from the blood-stream during the period of renal failure the patient might sometimes be kept alive until renal function was re-established.

The removal from the blood of these "retention products" has been attempted experimentally in the *past by various ingenious means, such as employing* the peritoneum as a dialysing membrane and the perfusion of isolated loops of gut. The withdrawal of blood, separation of the plasma, and return of the corpuscles to the subject (plasma phæresis) was tried by ABEL and his co-workers,[1] who also attempted extracorporeal dialysis of the blood.[2] The possibility of such dialysis has stimulated a good deal of research, but, apart from THALHIMER's use of an artificial kidney for the reduction of azotæmia,[3] there have been attempts at practical clinical application. Dia has, until recently, been chiefly handicapped by lack of a harmless anticoagulant and the inh difficulties in obtaining a suitable dialysing memb and constructing a dialysis apparatus of suffi capacity. Dr. W. J. KOLFF[4] and his colleague Holland have now apparently solved these probl *and the result is* an "artificial kidney", whic sufficiently practicable for use in the wards. It pity that KOLFF has used this term for his instrum for "artificial glomerulus" would more accura describe its aims and function; but the more glamo title will no doubt persist, so it should be pointed that KOLFF is not its originator; the name app to have been first used by ABEL in 1913.

The use of this *artificial kidney is simple, once* appropriate patient has been selected. A glass cann is introduced into the radial artery; the patient is gi heparin, and a minute later blood is allowed *to* through a rubber tube to the machine. The mach contains a 'Cellophane' tube, 1–2 inches in diame and 30–45 metres long, wrapped round a rotating h zontal cylinder, part of which is immersed in "r ing" fluid. The blood, after traversing the "kidne once only, is returned to the patient via a g cannula fixed in a superficial vein. Air bubbles clots are excluded from the reintroduced blood b simple and apparently effective glass filter. blood moves through the cellophane tube by grav and is returned to the patient by pumping rinsing fluid, through which the cellophane dialys tube is passed as the cylinder rotates, is a clean not necessarily sterile solution of sodium and pot sium chlorides, sodium bicarbonate, and gluco The surface area of the dialysing membrane in artificial kidney is about the same as that of human kidney. The cellophane tube takes half litre of blood, which is passed through in about fo minutes, so that large volumes can be dialysed a few hours.

KOLFF has reported results with his artific kidney in 17 cases of chronic and acute uræm including cases of malignant hypertension wi contracted kidneys, bilateral renal tuberculosis, acu glomerulonephritis, postoperation uræmia progre ing to oliguria and anuria, bichloride of mercu poisoning, and uræmia following the use of chem therapeutic substances. Only 2 of these patier survived, but the chances of survival were practica nil in the fatal cases, some of which, however, show temporary improvement after dialysis. One of surviving patients, who had developed the anu after receiving sulphapyridine subsequent *to* course of sulphamethylthiazole, might well ha recovered in any case with appropriate treatmen which was duly administered. The other surviv was remarkable and might be *credited to the artifici* kidney.

A woman of 67 was admitted to hospital with feve jaundice, signs of acute cholecystitis, and almost com plete anuria; the small quantity of urine passed w cloudy and contained red cells and much albumi Cholecystitis and acute glomerulonephritis was dia nosed ("a hepatorenal syndrome, if you like," Dr. KOLF remarked) and the patient was given sulphathiazole f

days. Her temperature fell, but the anuria persisted. er 8 days the blood-urea reached 390 mg. per 100 c.cm., potassium rose "alarmingly," and the alkali reserve to 40 vol. per cent. Cystoscopy was performed and right pelvis was washed out without effect (the left ter was obstructed). The artificial kidney was then d and 80 litres of blood passed through it in 11½ urs. In this time 60 g. of urea was removed by lysis and the blood-urea dropped to 121 mg. per c.cm. and the potassium from 55 to 19 mg. per c.cm. There was some clinical improvement but the nary output continued poor for some days and the od-urea rose again to 172 mg. per 100 c.cm. However, the urinary flow and concentration slowly improved d 2 months after the dialysis the patient was well. e was seen 5 months later in "excellent condition."

OLFF is convinced that this woman would have ed had she not been treated with the artificial dney, but this opinion must be accepted with reserve view of the remarkable recoveries from apparently peless situations reported in cases of acute renal lure developing in such conditions as blackwater ver. In his recent lecture to the Medical Research ociety, however, reported on another page, **Kolff** nounced 3 more recoveries in 8 additional cases, cluding a child of thirteen years with acute omerulonephritis following exposure, whose condion was considered beyond hope by the physician ho sent her to him. It is evident that with increasg experience and confidence the clinical net is ready being cast wider, and this should hasten the tisfactory assessment of results.

The substances removed by dialysis of uræmic ood have been carefully studied by **Kolff** and his lleagues. The blood-urea concentration was unirmly lowered after dialysis, as will be seen from the ble (adapted from **Kolff**'s book [4]).

OD UREA LEVELS (MG./100 C.CM.) BEFORE AND AFTER DIALYSIS

Specimen of blood	Case					
	12	13I	13II	14	15I	15II
efore dialysis	203	704	386	548	389	375
fter dialysis . .	89	192	187	263	159	228

The maximum amounts of urea were removed from ose patients in whom the blood-urea was highest efore dialysis. Creatinine and uric acid were milarly reduced by dialysis. Provided the composition of the rinsing fluid in the bath was kept nstant, the sodium content of the blood was altered ttle by dialysis; the serum-potassium level, which as high in some patients, was lowered by dialysis, d other substances present in the blood, such as lphonamides, were partly removed. Where the bject was acidotic, small amounts of an appropriate lution of sodium bicarbonate were introduced travenously before dialysis.

Kolff has clearly shown that the rapid extrarporeal dialysis of blood in large quantities is a acticable proposition, and he has provided evidence dicating that in some cases such dialysis may tide patient over a period of acute renal failure and keep m going until renal function is restored. He has asked mself the important and highly relevant question: Are all the substances responsible for the clinical ndrome of uræmia being removed by dialysis?" d has supplied his own answer: "It is not one efinite substance that causes the intoxication and only in exceptional cases one definite substance will reach concentrations which would be toxic if it were alone. It is the sum of all the detrimental influences, of all the retained substances which leads to uræmia. Up till now not a single substance is known to us which might participate in this intoxication and is *not* being removed by dialysis."

The importance of the artificial kidney in research is obvious, but its clinical scope has to be established. At the moment it seems that any form of acute uræmia might benefit from its use. Anyone who has had to watch with furious impotence the final desperate stages of anuric death in blackwater fever or traumatic shock will welcome its development. It is to be hoped that Dr. **Kolff**'s apparatus will be given an extensive clinical trial, particularly in those potentially reversible renal syndromes which **Maegraith** and his colleagues [5] call "renal anoxia."

Poliomyelitis in Mauritius

During the first five months of 1945 there were over a thousand cases of poliomyelitis among the 419,000 people of Mauritius—an attack-rate comparable with the 1916 outbreak in New York and the 1942–43 outbreak in Malta. An incidence of this magnitude in an island community offered exceptional opportunities for an epidemiological field study which were fully grasped by Professor **Seddon** and his team,[1] who followed up over seven hundred of the cases and have carefully analysed the results. Their clinical observations are described in this issue.

Owing to the war very few people came to Mauritius between October, 1944, and April, 1945. It was therefore possible to exclude, with some certainty, the introduction of the disease from abroad. Another fact suggesting that the outbreak was an epidemic of an endemic disease was the relative immunity of older people, 95% of the cases being in children under ten years of age. The outbreak began soon after a cyclone had done much damage all over the island and at a time when intestinal diseases were increasing in prevalence. There was however no evidence that previous intestinal disease rendered individuals susceptible to poliomyelitis. Starting late in February, most of the cases occurred during the next 6 weeks, with a peak incidence in the third week in March. In towns there was usually a rapid rise and then an equally rapid fall in the number of cases, but in country districts the infection appeared to spread more slowly and mainly along the roads. In many places the first cases were the children of shopkeepers or lorry-drivers who had frequent contacts outside their own districts. In towns the attack-rates were lower at all ages than in rural areas, and in very densely populated places there was an inverse relation between the population-density and the attack-rate. It seemed therefore that the relative immunity of town-dwellers must have been acquired early in life and that it was to some extent increased by overcrowded living conditions. Boys were more often attacked than girls, and of the three main racial groups in the island the Chinese suffered more heavily than the Indians or Creoles. Greater opportunity for contact with strangers is suggested as the explanation of differences in the sex and race specific attack-rates, the Chinese section of the population, though small in number, being almost all shopkeepers.

[5] Maegraith, B. G., Havard, R. E., Parsons, D. S. *Lancet*, 1945, ii, 293.

[1] McFarlan, A. M., Dick, G. W. A., Seddon, H. J. *Quart. J. Med.* 1946, 15, 183.

Contact—using the term in the widest sense and including all possible forms of transfer from cases or carriers—seemed to the observers of this outbreak to be the most important factor in the spread of infection. In nearly a quarter of the cases, direct or indirect contact with a previous case could be established. In families with a case, the proportion of adults engaged in occupations taking them away from their home district was significantly higher than in the population of their district as a whole. Except in one village, where an explosive incidence may have been due to infected ice-cream, no evidence was obtained that water, milk, or any widely distributed food had acted as a vehicle, and flies did not seem to be greatly concerned in the transmission of infection. It was thought that fæcal spread was uncommon and probably less important than spread by pharyngeal secretions.

Observations on multiple cases in single households led to the important conclusion that the patients were commonly infectious early in the incubation period, which, judged from histories in which there was a short or limited period of exposure to infection, was the usual 8–14 days. This drew attention to the M-shaped or "dromedary" pyrexia exhibited by some patients—a transient fever with vague symptoms lasting a day or two followed a week or so later by the main feverish illness culminating in paralysis. There was reason to believe that this preliminary rise of temperature, sometimes seen within 4 days of exposure to infection, marked the beginning of infectivity. The rate of spread from village to village and the explosiveness of the whole outbreak were inconsistent with as long a time between exposure and the development of infectivity as the commonly accepted 8–14-day incubation period, and it was concluded that a frequent result of exposure to poliomyelitis virus is the development 1 to 4 days later of infectivity occasionally accompanied by a minor illness but not by paralysis; if paralysis develops at all, it appears a week or so later as part of a more clinically obvious illness. During the Mauritius outbreak there were only four cases of poliomyelitis with paralysis among the garrison troops who had been isolated as far as possible from the civilian population But in the later stages of the outbreak at least two hundred of these troops had a mild "pyrexia of unknown origin." Unfortunately, lumbar puncture was not done in any of these cases, but their minor illness may have been a non-paralytic reaction to infection by the poliomyelitis virus. Laboratory investigation has shown that some contacts excrete the virus from their pharynx or bowels, though they have so far shown no sign of illness or at most a trivial indisposition often regarded as an influenzal cold or gastric influenza. According to McFarlan and his colleagues[1] such minor illnesses, like the first limb of the dromedary pyrexia in some paralytic cases, are probably "illnesses of infection," commonly occurring within 4 days of exposure, and these contacts are infectious a week or so before paralysis would be expected This view is supported by Gear and Mundel,[2] who mention a boy who had poliomyelitis virus in his stool ea the incubation period and infected others at 4 days before he became ill himself.

Events in Mauritius supported the idea that d an epidemic of poliomyelitis the obvious wav paralytic cases is merely the trailing and com tively non-infectious shadow of a much larger and infectious wave comprising healthy persons excre virus; abortive cases (i.e., examples of "illne infection" which does not proceed to clinic recognisable poliomyelitis); and paralytic cases alre in the incubation period, some of them showing first hump of a dromedary fever. The spread virus by the pharyngeal and fæcal excretions of components of this initial wave, which precedes paralytic cases by at least a week, may explain hitherto baffling features of poliomyelitis in small large communities. It throws light, for instance, the conclusion drawn by Stocks[3] from a statist analysis of the records of poliomyelitis in Lancas during 1920–29—that for every recognised case least one hundred other people became infected were presumably immunised. None of this solves problem of effectively controlling poliomyelitis epidemic form, but if the chief factors in the sprea *poliomyelitis are the secretions of the human phar* and aerial transmission of virus, then the best prosp of control seem to lie in the development of protect inoculation and a search for the unknown fact which *determine* why *most* of those infected esc invasion of the central nervous system.

Annotations

DOCTORS STILL UNEMPLOYED

The Government's postgraduate scheme for demo lised doctors was originally planned with two princ aims: it was to provide for young doctors some of hospital experience they missed by their service, and enable those who had planned to specialise to res their interrupted training. For would-be special the way has now been eased by a relaxation of the c ditions required of applicants for class III posts, and a promise to increase both the tenure and the numbe these posts. These extensions of the training scheme, the new £1000-a-year appointments for fully qual specialists which the Minister is encouraging hospi to establish at Treasury expense, reflect concern that greatest possible number shall be trained and retai in the specialties so as to meet the requirements of new National Health Service; and if the new terms fully applied, specialists, actual and potential, sho have little difficulty in bridging the awkward gap betw now and 1948.

No similar offer has been made to demobilised gen practitioners, though their difficulties are also ac Young graduates who were not established in prac before entering one of the Services can apply for months' class I hospital appointments; but many not wish, and few can afford, to spend the next eight months in these or similar posts at the salary of a se houseman. Mostly, therefore, they seek work in gen practice, where their future lies. But when they ap to an agency they find themselves at the end of a l and almost unmoving queue. Principals, they are t are biding their time until 1948, and are not want either successors, partners, or assistants. There indeed, evidence that this reluctance to take

w blood, which we noted some months ago,[1] has come more pronounced than ever. "I was told of a actice for sale the other day," said an agent: "I could ve sold it for certain to any of several dozen doctors. he first one I offered it to bought it the next day." hese unemployed doctors are not a true surplus; there e not too many but too few in practice. This was evitable during the war because other claims came first, t today there is no such excuse.

Several ways of ending this artificial separation of ctor from patient have been proposed It has been ggested, for example, that the limit of 2500 on the umber of patients which a doctor may have on his anel list should be reimposed. This may commend itself s just and reasonable; but it is not enough If, before 948, the public is to have the fullest possible general-ractitioner service, those now in practice must be urther persuaded to share work of which they have ore than enough with those that have none A correspondent of the *Manchester Guardian* (Nov. 11) suggests n announcement that compensation under the Act will be paid at 1947–48 (not 1939) values, which would, he thinks, lead many doctors to employ assistants to enlarge their practices. The final alternative is active support from the Government. The Minister is understandably ore reluctant to subsidise the general practitioner than he specialist, because the immediate benefits in training, nd the remote advantage for the new service, are less bvious. But these doctors are mostly of the younger eneration, and without any practical knowledge of ivilian general practice. When the service comes into being the demands on the country's practitioners may be greater than ever before, owing to the large number of patients who for the first time will be offered free medical attention. It would help the service to get off to a good start if, in the meantime, these doctors were trained for their responsibilities by an apprenticeship under those who already have experience of practice.

The future service, we are told, is to concern itself ore with preventive methods. For their success these depend on genuine understanding between the public-health and the clinical services—an understanding which hitherto not been as close and cordial as it might. The Minister might therefore like to encourage some of those for whom a place in practice is not immediately found to spend the coming months gaining first-hand experience in the various departments of public health; he would thus be assured of a group of general practitioners having a particular understanding and sympathy for preventive practice. Those that are not absorbed into practice should certainly not be left to kick their heels until they are needed, as they will be, to help in the operation of the Act; to rest content with this continued unemployment is to accede to the attitude that the general practitioner needs no special knowledge or experience beyond what he has gained from undergraduate training and casual hospital appointments.

CHLORIDES IN CEREBROSPINAL FLUID

THERE still seems to be some doubt about the interpretation of chloride levels in the cerebrospinal fluid (C.S.F.) in the diagnosis of meningitis. Honor Smith,[1] in her recent paper to the Tuberculosis Association, rightly emphasised that there is no level characteristic of tuberculous meningitis.

Nearly twenty years ago, Linder and Carmichael[2] demonstrated that the fall in the C.S.F. chlorides in meningitis was associated with a fall in the serum of plasma chlorides, and the same approximate relationship between C.S.F. and plasma chlorides has been shown to hold for other conditions. For example, a low level of serum chlorides is common in nephritis and constant in alkalosis, and in the latter condition the lowest C.S.F. chloride levels of all are met with. In infection in general, and in tuberculosis in particular, there is often a fall in the serum chlorides, and this is mirrored in the low C.S.F. chlorides, irrespective of whether there is meningitis or not. In the "meningism" associated with lobar pneumonia and other conditions C.S.F. chlorides of 650 mg. per 100 ml. and lower may be met with without any evidence of meningeal infection.

In true meningitis, as shown by raised protein and cell contents of the C.S.F., there is usually, though not invariably, a fall in the chloride level of the serum and hence of the C.S.F., and this fall is usually, though again not invariably, greater in tuberculous than in non-tuberculous meningitis, but the difference is a statistical one and may be misleading in an individual case. Allott[3] has shown that in about 50% of cases of tuberculous meningitis there is a C.S.F. chloride level of 640 mg. per 100 ml. or lower on first examination, whereas for non-tuberculous meningitis the 50% level is 675 mg. per 100 ml. Very low C.S.F. chloride levels are commoner in tuberculous than in non-tuberculous meningitis, and Allott found 25% of tuberculous but only 5% of non-tuberculous meningitis cases with levels below 600 mg. per 100 ml. on admission to hospital.

The cytology of the cerebrospinal fluid in the two main forms of meningitis is usually distinctive, the pyogenic form containing numerous polymorphs and the tuberculous form predominantly lymphocytes. But difficulties are sometimes met with here also, since in the early stages of tuberculous meningitis there may be only a slight rise in the cell content and more than half the cells may be polymorphs—a finding similar to that in poliomyelitis and virus encephalomeningitis. Tubercle bacilli can be found in smears in a fair proportion of cases of tuberculous meningitis if the C.S.F. is examined repeatedly, and they can be grown in culture from the majority, though, owing to the slow growth of the tubercle bacillus, the culture result is often obtained only after the patient's death. Notwithstanding these difficulties, the characters of the C.S.F. tend to change towards the "typical" finding of high lymphocytes and very low chlorides as the disease progresses; and most cases can be diagnosed with certainty by repeated examinations, even if the first specimen of fluid gives equivocal results.

SCIENTIFIC LIAISON BETWEEN NATIONS

UNTIL the first world war, science had been considered to be above the battle. The example usually given is that of Sir Humphry Davy visiting France at the height of the Napoleonic wars, and being honoured by Napoleon himself. From 1914 to 1918, however, the scientist was found to be such a vitally important part of the nation's war effort that this scientific internationalism broke down completely; only medicine escaped, and the doctor was still expected to treat friend and enemy alike. Between the two wars attempts were made by various organisations, notably the League of Nations, to bring together scientists from all countries, and the last few months has seen a heartening revival in such attempts—for example, the British-Swiss Medical Conference and the International Medical Conference in London. In a special number of *Chronica Botanica*, published in the autumn of last year, B. Cannon and R. M. Field review the aims and methods of international scientific relations, both past and future.

Their memorandum starts by emphasising that "war is a great stimulus to national, and to limited international, coöperative scientific research in most of the applied sciences." What is needed today, to quote Joseph Needham, is "an attempt to combine the methods which the world of science has spontaneously worked out for itself in periods of peace with those which the nations have had to work out under the stress of war." To this end a questionnary was sent out to the various international congresses, unions, and associations with a view to finding out how much exchange of information (other than for war purposes) had taken place during the war years between different countries, and how much post-war activity was anticipated by the congresses, &c. Most were of the opinion that international scientific relations are of great value in helping mankind towards a more settled form of existence. A few thought it would be better to revert to the old system under which individuals or societies arranged to meet among themselves; but, as Needham points out, the fallacy of this attitude is that the picture of world science looks very different when seen from Rumania, Peru, Siam, or China, than from such centres as Paris, London, or Washington. For hundreds of years the growth of science and technology has been most rapid in those countries with greatest access to raw materials; the upheavals and divisions produced by the search for raw materials has been one of the profoundest causes of wars in the past. The memorandum emphasises this, and also the enormously increased bearing which science has on human welfare in normal peace-time activity. At the same time there is the paradox that the man in the street learns less and less about the advances in science owing to its increasingly technical language; and one of the most constructive suggestions made at the International Conference on Intellectual Coöperation at Havana in November, 1941, was that there should be a new class of "intermediary" scientists to convert a highly symbolised mathematical language into a literary form which can be understood by most men and women with an average general education and is at the same time scientifically accurate.

Perhaps the most urgent reason why scientists should meet together and collaborate is to avoid the suspicions which arise from a narrow nationalistic outlook. How necessary this is may be judged from the fact that in the past the Russian government, through its Academy, has preferred to communicate with individual American scientists rather than with their organisations. Scientific bodies work in ways which differ considerably, and one of the recommendations at the end of the memorandum suggests that "the foreign secretaries of the Russian Academy of Science, the Royal Society of Great Britain, and the National Academy of Sciences of the U.S.A. should explore the possibilities of an inter-Academy study of their international relations in those phases of science which are of benefit to mankind, and inimical to none."

EQUAL PAY

Two years ago a Royal Commission, with Lord Justice Asquith as chairman, was appointed "to examine the existing relationship between the remuneration of men and women in the public services, in industry and in other fields of employment; to consider the social, economic and financial implications of the claim of equal pay for equal work; and to report." Briefly, they find [1] that while equal pay is usual—and indeed harmless—in the professions (except nursing and teaching), it is unusual in the civil service and in industry; and while all the members favour its introduction into teaching, the civil service, and the Post Office, the majority feel unable to recommend it in industry and commerce. As to nursing, they content themselves with stating without comment the position since the Rushcliffe reports appeared. A note of thankfulness sounds in the remark of the majority that their terms of reference do not call them "to attempt any final summing-up of the relative importance of ensuring exact ju between individuals on the one hand and oiling the wh of economic progress on the other." In this disclaimer minority—Dame Anne Loughlin, Dr. Janet Vaughan, Miss L. F. Nettlefold—have no part, holding that " claims of justice between individuals and the development of national productivity point in the same direction."

The commission note that for most of its advoca "equal pay for equal work" means a fixed rate for t job; it does not mean equal pay for equal value to t employer. The majority believe that the lower w of women can be accounted for by lower efficiency while the minority argue that the main cause of th low earnings is the exclusion of women from a numb of trades in which, given opportunity and training, the would be efficient workers, combined with weak trade union organisation. Some legal restrictions on nigh work, and, in some trades, on length of hours worked b women, reduce their value to employers; but, as th minority remark, medical evidence suggests that wome are as well suited to night work as men, and restriction on the length of hours worked will matter less as standar working hours are reduced. In the same way, th greater physical strength of men will have less importanc as machinery is substituted for muscular power. I was alleged by some employers that women are less abl to deal with "surprise situations" than men. Finally it is admitted that absenteeism is commoner amon women; but this is due, as all agreed, to the famil responsibilities of women, and their attitude to employment, rather than to physical disabilities. The minorit suggest that it is "both unfair and economically undesirable that an individual woman should be penalised, eve if she is never absent, and an individual man benefited even if his attendance is poor, because, on the average men have a better record of attendance than women."

In any case, any difference in efficiency between the sexes is considerably less than the difference in wage-rates—women often being paid only about 60% of the men's rate. There are even statutory wages councils which discriminate against women merely because it is customary in their trades; and cases of this sort, the commission believe, should be remedied by Government influence. It is worth recalling that professional women, already assured of the right to equal pay, were often given that right by strong organisations. They include doctors, dentists, physiotherapists, radiographers, university teachers, actresses working for ENSA, journalists, and some librarians. Nor was it always easy to enforce the principle as medical history shows. But women in industry often have little sense of the value of organisation the proportion of trade-union members among working men just before the war was 37%, among women 11% by 1944 the figures were 61% and 29%.

The commission has produced a mass of valuabl information and argument, and its failure to reach mo unanimous conclusions is scarcely surprising in view the intricacy of the subject. A serious practical objectio to ensuring "exact justice" throughout industry is that by and large, women have fewer dependants than men To give them the same pay would raise their standard of living relatively to that of the married man and his wife and children. Already, despite income-tax reliefs and family allowances, the pecuniary penalties on marriage and parenthood are so severe as to be socially harmful, and, unless we are prepared at the same time to introduce adequate dependants' allowances for all workers, it might do more harm than good to equalize wages generally between men and women. The fact that men usually have heavier responsibilities at home is one of the reasons why the average employer, given a choice between a man and a woman at the same rate of pay, will usually prefer the man—which means incidentally that enforcement of equal pay for women would increase any risk of unemployment for them. Since many women have expensive dependants, and many men have none, this habit among employers is only a very blunt instrument of social justice. Yet it is wielded occasionally even in the professions, where the custom of equal pay for equal work has sometimes been known to deprive women of appointments for which they were fit. We do not regret that custom, but it is insufficient by tself. As the commission point out, our present family allowances and income-tax rebates are insufficient; and we doubt if any effort to make remuneration equitable will get far without the inclusion of larger allowances for dependants.

SYNTHETIC PENICILLIN

THE recent announcement in the press that penicillin G (I) has been synthesised in America, though accurate in fact, may have been misleading in emphasis, for the yield is very small.

During the war penicillins F and G (I and II) were obtained in traces by synthetic processes which were worked out simultaneously in Oxford and in the Merck laboratories in New Jersey, U.S.A. Secrecy had to be maintained at the time, but a joint monograph is shortly to be published. It was clear in the early stages of these investigations that the antibacterial product obtained was penicillin, but more evidence on this point was gathered by workers at Cornell University, who also obtained the product in a high degree of purity. Du Vigneaud and his colleagues[1] of the Cornell biochemical department have now described the synthesis of penicillin G, by the interaction of *d*-penicillamine and 2-benzyl-4-methoxymethylene-5 (4)-oxazolone. There seems to be no likelihood that a way will be found of increasing the yield, and indeed the chances of any other reasonably cheap penicillin synthesis being developed are remote. On the other hand, the work done by British and American chemists may well lead to the preparation of [illegible]w "unnatural" penicillin compounds which may have a [illegible]le something that the natural products haven't got.

1942: THE TIDE TURNS

THE coincidence of the celebration of the fourth anniversary of El Alamein and the publication of the Registrar-General's report on 1942[1] had a certain significance, for 1942 marked the turn of the tide in the medical as well as the military sense. 1940 and 1941 were marked by all the vital statistical indications of the effects on national health of the strains of total war. Mortality rom pulmonary tuberculosis, respiratory diseases, and cerebrospinal fever had risen considerably above their pre-war levels; the downward trends of infant and maternal mortality had been halted, and there was a rise in the civilian death-rate. Some of this mortality was due either directly to the air-raids, which caused 2,215 deaths in 1940 and 19,543 in 1941, or indirectly to the rise in infectious diseases resulting from the congested living and working conditions and poor diet inevitable at the time.

The recovery in our military fortunes which 1942 brought was associated with a striking improvement in the statistical measures of national health. The most sensitive indices of well-being—infant mortality and pulmonary tuberculosis death-rates—fell to record low levels of 51 per 1000 related live births and 542 deaths per million of the civilian population at all ages. Epidemic diseases, such as whooping-cough, measles, and scarlet fever, all had low mortality levels; cerebrospinal fever caused only 1143 deaths compared with the 2459 deaths of 1940. These results were at least partly the result of the less harassing conditions of life suggested by the fall in the number of air-raid deaths to 3891, most of which occurred in the "Baedeker" raids on Bath, Exeter, and Norwich. The achievement for the first time of a death roll from diphtheria below 2000, however, can be fairly attributed to the Ministry of Health's immunisation campaign. A curious feature of these annual reports on the war years is the progressive decline, noted also in the first world war, in the number of suicides; from a pre-war annual average of 5000, the toll fell to 3416 in 1942.

The Comparative Mortality Index, which takes 1938 as a base line of 1·000 in the standardisation for age, was introduced in the 1941 report[2]; in that for 1942 it takes its place as a regular feature. From 1938 the trend in civilian mortality is clearly indicated by the C.M.I. Similarly the ratio of male to female mortality shows the disproportionate rise in mortality among the men of the civil population.

	C.M.I.	*Male-female ratio*
1938	1·000	1·343
1939	1·022	1·339
1940	1·171	1·382
1941	1·070	1·406
1942	0·942	1·416

The Registrar-General's report for 1945 is in preparation, and we may look forward to a resumption of the complete and up-to-date reports of pre-war practice.

ON THE STAFF

AT some hospitals junior honoraries are not distinguished from their seniors except, possibly, by an "assistant" before their titles. At many others the distinction is one not only of name but also of privilege: the assistant may, for example, be expected to see all outpatients, and may have under his personal charge only a few beds, the number depending on his principal's liberality. This practice is blessed by the years; but, as a correspondent indicated some months ago,[3] it is one that would best be abandoned. The division of duties is indefensible; work in the outpatient department no less than in the wards requires all the skill a unit can command; and there is much in favour of the care of the patient, after admission, being in the hands of the doctor who first examined him as an outpatient.

The assistant honorary, who, in any case, shares an equal weight of responsibility with others on the staff, should be rewarded at least by official recognition in the allocation of beds. St. Peter's Hospital for Stone, London, have now announced that the title of assistant surgeon is to be discarded there; all the honorary surgical staff will be called honorary surgeons and will control an equal number of beds, except perhaps for some slight advantage to one or two of the most senior. Junior honoraries elsewhere will hope that this example is not lost on other hospitals.

THE SCOTTISH BILL

THE Bill providing for a comprehensive medical service for Scotland was published last week. Though the scheme as a whole follows the English model, there are several interesting variations. For example, the provision, equipment, staffing, and maintenance of health centres will be the duty of the central health department, and though the Secretary of State is empowered to delegate this function to local health authorities he is, it is stated, unlikely to exercise this power widely in the early years of the new service. The main differences between the Scottish Bill and the English Act are described in our parliamentary columns.

further method of dialysis under trial was to isolate oop of ileum surgically, bringing both ends to the face of the abdomen and anastomosing the remaining stine. It had been shown that perfusion of such a p a metre long for 10 hours would remove as much as . of urea from the blood. Dr. Kolff concluded by fore- ing the time when a man in whom both kidneys had n removed might perform his nightly lavage, after ng about his ordinary daily business.

WOMEN DOCTORS IN WAR

At a meeting of the Medical Women's International sociation, held in London from Sept. 19 to 22 under the sidency of Miss Louisa Martindale, F.R.C.O.G., women ctors from Belgium, Denmark, Finland, France, Great itain, Holland, India, New Zealand, Norway, Sweden, itzerland, and the United States described the work their colleagues during the war.

IN THE FORCES

Dr. S. Lamotte (France) said that French medical men had won an uncontested place in the Army ring the later campaigns. The occupation of France ade it impossible to set up an officially recruited force, t a body of women doctors got together and worked ith the French Army in France, North Africa, Italy, ngland, Alsace, and Germany—the A.F.A.T. (the rench women's auxiliary army force), formed in North frica in 1944, contained a medical corps of over 150. fter the liberation the corps set up centres for refugee ildren and treated deported men in Germany. Dr. amotte herself later joined a biological and therapeutic search station of the medical corps which studied oblems of malnutrition and infection.

Dr. Letitia Fairfield (London), one-time woman edical adviser to the War Office, said that medical omen had been used almost interchangeably with en. The only difficulty that had arisen was over utine inspections in men's barracks. In the recruitment nd training of the A.T.S. they had also been able to ggest points where the routine of the Army must be apted for a women's service. Before the end of the war ere were 600 women doctors in the Army. Dr. Dorothy enwick (London) said that women doctors were given mportant work in the Air Force and were well received y their male colleagues. She herself covered 22,000 iles a year on visits of inspection, and every airwoman ad the opportunity of consulting a woman medical fficer.

RESISTANCE

Dr. Fog (Denmark) told how medical women in her ountry had secretly received weapons, helped and ansported saboteurs, hid refugees and parachutists, nd acted as couriers. Constant coming and going made onsulting-rooms a safe place of rendezvous, visits to atients afforded a means of conveying information, mbulances and hospitals were often used to save Jews nd others whom the Germans were seeking, and ounded saboteurs were kept in secret clinics and private ouses. Many women doctors were discovered and sent concentration camps for long periods. Dr. Droever onnet (Holland) related how one woman doctor was leader of the whole Dutch movement, and how another ho used her house as a centre of the resistance was rrested and killed by the Germans. Yet another, as hief doctor in a German internment camp, was able help some internees to escape.

Dr. Astrid Guldberg (Norway) told of ten women octors who were imprisoned for their share in the esistance, and of one who went voluntarily with her ewish patients to Germany, and has never been heard f again. Dr. de Blainville (France) was arrested for er resistance activities in 1944 and sent to Fresne rison, near Paris, and then to Ravensbrück, the biggest oncentration camp for women in Germany, where there ere 16,000 internees at one time with no medical ttention. Huts were densely overcrowded, and infection as rife. Examination for pregnancy was conducted ith no attempt at cleanliness, and prostitutes mingled ith healthy women. Experiments were carried out on the prisoners with the greatest cruelty. Many women were treated as guineapigs and then put to death.

RECONSTRUCTION

Dr. Bergerot (France) said that 600,000 arrests were made in France during the war, and there was still no news of 250,000 people who were deported to Germany. There was an order in France that employers must take back their old employees, but this created difficulties because so many of the returning men were suffering from emotional instability, loss of memory, and physical deterioration. Dr. Jeisler (France) declared that the peak of delinquency and emotional disorder in children was reached in 1942, and had since lessened. The war had increased psychological disorders in children, but only among those who had already shown such tendencies. A few children had been found living wild in bands near the towns at the time of the wholesale deportations. Some, who had lost their parents or had seen them maltreated, wanted to avenge them. Jewish children had been particularly difficult. The surviving children of the deportees were like little savages. They had their own laws and their own chiefs and were brutal, but with patience they were gradually coming back to normal.

Dr. Middlehoven (Holland) said that Holland had set up relief units, which had enabled them to combat in a short time the most cruel consequences of the hunger blockade. Tuberculosis and syphilis had increased alarmingly, and congenital syphilis was now not uncommon. The physical condition of the Dutch population of the Netherlands East Indies, who had been evacuated to Holland after the capitulation of Japan, was deplorable, and dispensaries for tropical diseases and nutritional deficiencies had been set up. She was impressed by the training and education which the children had been given by their mothers in the Japanese camps. They behaved much better than the Dutch children, who practically ran wild during the war years. Those who had collaborated with the Germans presented another grave problem. They were still in camps, their children had been taken from them and placed in homes or with foster parents, as camp life was not suitable for them, and it was feared that they would become infected with Nazi ideas.

The next international congress is to be held in Holland, in June or July, 1947, when the Place of Medical Women in Post-war Reconstruction will be the topic for discussion.

MENTAL DEFICIENCY IN NORTHERN IRELAND

The Mental Health Services Committee appointed by the minister of health and local government to investigate the problem of mental deficiency says in its report[1]:

> "In Northern Ireland there is no Mental Deficiency Act, no institution, no community supervision, and there is only one special school (in Belfast), which is unable to meet even local needs. Apart from the inadequate provision made by the Education Acts and the Poor Relief Acts, the responsibility for dealing with mental defectives has not been placed by statute on any authority and, for the most part, these unfortunate people lead a hopeless existence at home, in Poor Law institutions, or in mental hospitals . . . we cannot over-emphasise the need for early action."

Ascertainment, the committee suggests, should be improved by placing on medical practitioners and on schools a statutory obligation to notify the mental-deficiency authority of suspected deficiency. Defectives should be dealt with by the ministry of health as the central authority, and by a regional authority composed of representatives from county and county-borough councils and other interested bodies; this regional authority should be responsible for ascertainment, the provision and administration of institutions, and the supervision of defectives in the community. Local mental-health committees should be formed to advise the regional authority and coördinate the activities of those interested. The mental-deficiency authorities should be either amalgamated or closely associated with the authorities administering all the other mental-health services. It is proposed that the mental-deficiency authority shall be given compulsory powers to deal with all ascertained defectives.

---

[1] H.M. Stationery Office. 1s.

> "It is wrong to wait until the defective gets into trouble or runs foul of the law before affording him the care, supervision, and training which his mental condition requires and which it is in his own interests to receive. Mental deficiency is often hereditary, and we consider it wrong to leave any power in the hands of mentally defective parents. . . . It is not suggested that all defectives would be sent to institutions."

The committee favours a single colony with, eventually, 1000 beds, to be established within 20–30 miles of Belfast. A school should be included, where the opportunity of education might be extended not only to those unsuitable for ordinary or day special schools but also to the so-called ineducable defectives. Suspected defectives should be admitted for a short time to an observation unit which should not be in, but should be near, the colony. Defectives in the colony could be sent out on licence to a hostel, a private house, or their own homes. The provision of sheltered employment, the committee concludes, should be considered when mental-deficiency legislation is being drafted.

NOBEL PRIZEMAN

THE award of the Nobel prize for 1946 in physiology and medicine to H. J. Muller, of Indiana University, will be welcomed by scientists all over the world. Muller's genetical work is widely known mainly on account of his spectacular demonstration in 1927 of the effects of X rays in producing mutations. His imaginative power at once enabled him to develop the discovery in collaboration with others, to plan further experiments, and to appreciate the evolutionary significance of the new knowledge. He focused attention on the essential property of the genic substance—namely, its ability not only to copy itself but, after being changed by mutation, to copy the alteration as well. Apart from the impressive contributions of Muller in the experimental field, his capacity to integrate many aspects of the subject has made him an outstanding figure in genetics. At the present time the medical importance of the knowledge of radiation effects on germ cells is becoming increasingly obvious, and Muller's work is now of more practical value than even he himself could have foreseen twenty years ago.

Public Health

Tuberculosis under the National Health Service

THOSE who have worked among the tuberculous hold that this disease presents a special medical problem and must be considered apart from other social diseases. Dr. Norman Tattersall, principal medical officer of the King Edward VII Welsh National Memorial Association,[1] fears that under the National Health Service Bill the need for unity of tuberculosis control is being lost sight of; chest cases are to be referred to the care of a chest physician, bones and joints to the orthopædist, and other forms to the appropriate special department. Though he agrees that each special department must direct the treatment of particular phases of infection, yet tuberculosis is always an infectious disease combined with a social problem, and all forms must be subject to broad control of the disease, with the family and not the individual as the unit. "If this is lost," he writes, "we shall witness a reversal of the principle which has guided the development of the service ever since Sir Robert Philip opened the first dispensary in 1887."

Sir Edmund Spriggs, in a discussion of the same subject at the annual meeting of the association's board of governors, said that the Bill as at present drafted seems to hand over tuberculosis to general physicians, surgeons, and health visitors, though pulmonary cases would be protected to some extent by the fact that some of the new chest physicians would be former tuberculosis doctors. For some fifty years he has watched the development of the medical and surgical management of tuberculosis, and has concluded that it does call for special experience. "A doctor without that experience is no more able to do the best possible for a random series of cases of tuberculosis than he is to perfor succession of varied operations before he has had surg training." Among his reasons for regarding tubercu as a problem of its own he gave the following:

1. It is a general disease with local manifestations. division into pulmonary cases and surgical cases, to be tre by physicians and surgeons respectively, is not wholly so At the North Wales Sanatorium, Dr. F. S. Hawkins and G. O. Thomas recently found pulmonary disease present no less than a quarter of 143 so-called surgical cases. complication might easily have been overlooked if the pati had been transferred to general surgical wards, beyond supervision of a tuberculosis specialist.

2. Many tuberculous patients must be segregated, for t own sakes and that of the community.

3. They need treatment over a long period.

These last two considerations mean that tuberculous c must be managed on a different plan from other dise amenable to arrest and cure.

4. Pulmonary tuberculosis is the commonest chr disease of young people. Other common chronic dise such as heart disease, arthritis, and arteriosclerosis, oc mostly in later life, and many of those affected are alre of pensionable age; others by care and treatment may g five or ten years of useful life. But every case *of tubercul in a young person which is arrested*, or *better prevent* brings to the community 30–40 years of possible usefulne The treatment of this disease, especially of early cases, t has a high economic value. "It pays handsomely."

Lastly, Sir Edmund believes that, to get the b results, the care and reablement of the dischar tuberculous patient and of his whole family should be the hands of specially trained health visitors who are direct personal relation with the expert tuberculo doctor. A liaison between the staffs of general hospit and tuberculosis hospitals is desirable and will bene both, but if the welfare of the patient is to be the fi consideration there should not, in his view, be fusion.

Paratyphoid in Sheffield

New cases of paratyphoid in Sheffield have now fall to 1 or 2 a day, and it seems likely that the source infection present in September and October has be eliminated, though it is still untraced and likely to rem so The total number of cases to Nov. 12 was 141. T younger age-groups have been most affected throughou and the illnesses have been of moderate severity, b with a remarkably profuse rash.

The authorities of Sheffield University felt th members of the staff and students should not be deni the protection by inoculation which has been so success in the Armed Forces. Arrangements were made T.A.B. inoculations to be carried out in the bacteriolo department on four days of one week and four days the succeeding week; 340 completed the course of t inoculations of 0·5 and 1 c.cm., and an additional 26 h one inoculation only. There were no serious reactio

This is not a new departure in Sheffield, for immuni tion against typhoid and against diphtheria was ma available to students and staff who desired it during t war years 1940–43, and large numbers took advanta of the offer. In view of the changed situation it was provided in 1944 or 1945. In all cases the immunisati was entirely voluntary and the diphtheria immunisati was naturally only given to Schick-positive subjects.

Infectious Disease in England and Wales

WEEK ENDED NOV. 2

Notifications.—Smallpox, 0; scarlet fever, 116 whooping-cough, 1549; diphtheria, 274; paratyphoi 66 (38 at Sheffield); typhoid 6; measles (excludi rubella), 3374; pneumonia (primary or influenzal), 48 cerebrospinal fever, 40; poliomyelitis, 25; polioenceph litis, 2; encephalitis lethargica, 0; dysentery, 69; pue peral pyrexia, 117; ophthalmia neonatorum 63. No case cholera, plague, or typhus was notified during the wee

Deaths.—In 126 great towns there were no deat from enteric fever, 3 (0) from scarlet fever, 2 (0) fro measles, 8 (1) from whooping-cough, 3 (1) from diphtheri 31 (2) from diarrhœa and enteritis under two year and 12 (1) from influenza. The figures in parenthese are those for London *itself*.

The number of stillbirths notified during the week w 273 (corresponding to a rate of 30 per thousand tot births), including 38 in London.

In England Now

Running Commentary by Peripatetic Correspondents

THOSE of us who have returned to England after some ars overseas find it a very different country from the ie we left. I am not referring to the physical changes war but to the changed mental outlook. Long-ntinued shortage of all the luxuries and many of the cessities of life has lowered the standards of honesty. en the most respectable people will go to extraordinary igths to get a little extra "off the ration," and, since gh taxation has made the investment of money for terest hardly worth while, people have taken to eculating in property to increase their capital. Car-aling is the commonest form of speculation—one hears people buying a new car for £600 and being offered 200 as they drive it out of the garage—but there are any others. Professional dealers in goods are com-aining that the amateurs are ruining their business. ne obvious result of all this property changing hands the creation of artificial shortages. Let us hope that e cry of "Every man for himself!" will no longer heard when the home markets become stocked with ough goods for everyone. Otherwise I shall be off to e jungle, where the decencies are observed.

* * *

Who will take up the cudgel on behalf of some of the ost hardly hit victims of the world rubber shortage? G.P.s of the pre-war days we used to see these now happy creatures at three, six, or even nine months' tervals and perhaps we scolded them gently for not siting us more often; but it did not really matter. those days Britain was supreme. We owned Malaya, d rubber was rubber; so if a few thoughtless ladies hung to their ring pessaries for more than the usual three onths we knew they were comfortable and did not eatly care.

Things are different now. These hapless women haunt r surgeries and monopolise our phones. "The ring u put in last week has slipped." "I can't walk. The ckache is terrific." "The rubber has perished and I've ly had it in a month." Many suffer in silence. They agine that we will think they are complaining about thing. Their housework becomes torture. Many nnot cycle. Others dare not lift a bucket of coal. At st we were inclined to blame ourselves. We fitted other ring and prescribed patience. But things did t improve and all round the story is the same.

Nowadays most rings are made of synthetic rubber. ey are thinner than formerly. The rubber perishes ickly and they slip out of place easily. The victims inarticulate. They will never write letters to the press bombard their M.P. with demands for better service. t something should be done about it.

* * *

One of your peripatetics, writing of a children's club Holland, remarked that English boys are not normally aid of the police. Nor are they—unless of course they ve been "up to something." Anyone who wants to relations between boy and bobby at their best ould visit one of the clubs run by police in some of great cities. Norwich started the idea more than years ago.

Perhaps the most important point about these clubs that they emphasise the friendly and helpful side of policeman's attitude to the junior ranks of the popula-n. Another thing is that a club (or anything else) der police management is likely to be efficient. They ve the knack of doing a thing thoroughly and well if y do it at all. The prevention of crime is the first lice function, and in no better way can they discharge ir duty than by directing the energies and interests the young into healthy channels and giving them the ht sort of examples to imitate and the right sort of als to aim at. Boy is a hero-worshipper by nature, and fortunately or unfortunately—he does not always ect his heroes wisely. Saintliness does not in itself ke any strong appeal to him. Even *honesty*, as such—d to say—evokes no enthusiasm. He wants toughness his hero, physical strength, and skill with the fist, e foot, or the gun. For this reason a good many of the youngsters who are most likely to go wrong avoid such entirely admirable organisations as the Boys Brigade, Boy Scouts, and so on; and fear of too much discipline often keeps them away from the Cadet Corps.

It's just these little "tough guys," often from bad homes and an unhealthy environment, that are most likely to get into trouble—sometimes serious trouble leading eventually perhaps to a life of crime, unless something is done to pull them up. Police have special opportunities of making contact with these types, and it is less difficult to get them to come to a police-run club than an ordinary one, because the policeman has at least some of the attributes the lad looks for in his hero: he is a bit of a tough guy himself, and the boy knows that there will not be any sloppiness in a police club. There will be well-run games and good boxing, things to learn which may be useful, and even perhaps the chance of picking up a good job later on.

Though several of our big towns have such clubs, until quite recently the experiment had not been tried in London. What can be done in a self-contained compact community like Norwich or Swansea is not so easy to achieve in a vague inchoate area like Hornsey or Lambeth. However, a start has now been made at Croydon, which is within police London. An energetic police superintendent, backed by other officers and a strong local committee of enthusiastic Croydon citizens, has opened and is running a club for boys in a district where nothing much of the kind exists. The superintendent and his friends want to strike a slightly new note. Every boy is to be made to understand that he has got to give as well as take: he won't get all the fun and games for nothing. His payment is to be in the form of service; he must qualify in first-aid and life-saving, and he must learn all about his municipality and how it is run. He will be taken to see the wheels go round—on visits to the town hall, the power station, the gas works, the hospitals, and other local institutions—and he will be expected to know about every kind of local activity of a public and semi-public kind.

Later this club may experiment on lines that have been successful in American cities, where they have what they call a "junior police corps." Boys who have been club members and have fulfilled their obligations as such are allowed to join the corps; they are given a uniform, and on state occasions when something is happening—a convention meeting in the town, perhaps—they turn out and make themselves useful, running messages, parking cars, answering inquiries, and so forth. All this is good. Something for nothing is an unhealthy principle, and by giving a boy responsibilities you develop his character and at the same time give an outlet to the natural urge to excel and be a bit of a chap in the eyes of his young companions. Also of course the best hope for our local government is to attract into it more sound men with no axes to grind, and the best chance of achieving that is to rouse their interest at an early age.

* * *

I agree with your peripatetic correspondent of Oct. 26 on the difficulty of judging the meaning of testimonials and personal letters, but I think he is wrong in interpreting, "He is an excellent teacher of the *list* type" as meaning, "You have been warned!" To my mind this means that the candidate is one who gives students lists of causes, symptoms, complications, &c., and usually simplifies the whole matter very much. Such a teacher is, as a rule, very popular and has a great following among students, especially if he is a good clinician. He tends to attract the poorer type of student, but gets many a man through his examinations when he would otherwise fail, and serves a useful purpose in the hospital.

At the opposite pole is the teacher who stresses the importance of principles rather than details which can be read in a textbook. He tries to make the student think for himself and not accept blindly what he is told, and rather emphasises difficulties instead of smoothing them away. This teacher has a smaller influence, but the better type of student follows him, and his educational value is much greater. Most teachers of course use both methods, but some rely more on "lists" and the others more on principles. Both kinds of teaching are necessary since the students, thank goodness, are not all of the same type.

Parliament

NATIONAL HEALTH SERVICE BILL

THE House of Lords on Nov. 6 considered the Commons' reasons for disagreeing with certain of the Lords' amendments. The LORD CHANCELLOR moved that the House "doth not insist" on the amendment which provided that the London County Council should delegate to the metropolitan borough councils the provision of maternity, child welfare, and home services. The Commons disagreed:

> Because it is expedient that all the services provided under Part III of the Bill in any area should be the responsibility of a single local authority, and the appropriate authority, in the County of London, as in other counties, is the county council.

The effect of the amendment, Lord JOWITT said, would be to destroy the unitary basis of the services. Speaking on behalf of Lord Latham, he gave the assurance that the L.C.C. were fully aware of the necessity of avoiding undue centralisation, and on May 28 the council had declared that they would entrust day-to-day management of the local health services to area committees to which members of the metropolitan borough councils would be elected. Members of those bodies would also be elected to the statutory health committee of the L.C.C. The area committees were to have real and genuine executive powers.

Lord BALFOUR OF BURLEIGH welcomed this assurance as far as it went, but said it unfortunately did not go very far. This was a thing on which the borough councils felt just a bit sore. He hoped that Lord Latham and the L.C.C. would be a little better than their word this time and play the game.

The Lord Chancellor's motion was agreed to.

BASIC SALARY

On clause 33 (arrangements for general medical services) the Lord Chancellor moved that the House "doth not insist" on the amendment that the remuneration of doctors providing general medical service should be by the capitation method, save in exceptional circumstances. The Commons had disagreed:

> Because it is inexpedient that the method of remunerating the doctors providing general medical services should be laid down in the Statute.

Lord JOWITT submitted that it was too restrictive to lay down the method of remuneration in the Statute. It had never been done in regard to national health insurance; it had always been left to regulations made after consultations with the profession. It was also, he suggested, inappropriate for the Medical Practices Committee to be the judge of "exceptional circumstances." It was for them to make recommendations to the Minister, upon whose shoulders lay the responsibility for securing an adequate service.

Lord LLEWELLIN said that those who had supported the amendment were anxious to see that more consideration was placed on the relationship of patient to doctor than on the relationship of doctor to the State. But he recognised that there was quite a lot to be said for not putting in the Act the exact terms of the doctor's remuneration when the discussions between the Minister and the medical profession had not been concluded. Since the amendment was carried by their Lordships the Minister had stated that it was intended, unless in exceptional circumstances, that the salary should be a minor element and that the main part of the remuneration would be by capitation fee. The amendment, he thought, had been valuable in evoking that statement from the Government. He accepted the Lord Chancellor's motion as he did not wish at that stage to wreck the Bill.

Lord HORDER still felt that the principle which underlay this amendment had not been modified by the Minister of Health, though he agreed that the posit had been clarified. The statement made by Mr. Be was a statement of faith on the part of the pre Minister, who could not, of course, speak for fut ministers. If the capitation method was done a with at some future time, then the fear which had ne been removed from the minds of the doctors would intensified. The Minister's statement called for a h gratitude, though his colleagues in general prac were left rather cold by this small morsel of com which had been thrown to them. If the Minister wis to have the medical profession with him, as he said did, then he might have gone further. It was doubtful whether the doctors were going to come willingly and enthusiastically to work this sche Lord Horder hoped they would. It was odd, he s gested, that so much was said about the doctors' secu when they said so little about it themselves. Th were not dissatisfied with a certain amount of insecu when they started, nor with a healthy spirit of comp tion as they went on.

Lord MORAN thanked Lord Jowitt on behalf of profession for the reasonableness which he had sho in the discussions, but regretted that he had describ this amendment as a blemish on the Bill. Even at t late hour Lord Moran thought it was fundamental t they should know exactly what was the doctors' attitu towards this proposal. The doctors found it v difficult to know why the political world was so anxi to provide them with security for which they had n asked. In his 25 years as dean of a medical school had never once heard the question of security discuss It was a fundamental belief throughout the professi that there was something profoundly wrong with a m if he could not make a livelihood in medicine. He wou go so far as to say that this question of a basic sala was a figment of the political imagination and had support in the facts of the doctor's life. As to t suggestion that the capitation fee led to abuses a undesirable practices, Lord Moran did not deny th there were isolated black sheep, but were they on th account to have the whole of the remuneration of all t rest of the honest members of the medical professi altered in a way which the profession almost unanimous felt might result in a deterioration of medical practi in the future? It was of enormous importance that t doctors should have confidence in the Ministry of Healt and that confidence would not be created if the politic world impugned the honesty of the great body of t profession. Generally speaking, doctors did not belie that the zeal and fervour of the rank and file of t Labour party for the basic salary was inspired sole by solicitude for young doctors. They believed that was an instalment which might be conveniently add to from time to time towards the introduction of a whol time salary. He entirely accepted what Mr. Bevan h said in the Commons, but Ministers of Health came a went, and this principle remained as a basic faith on t part of the political party which had so often express it. If ever this basic salary did become a whole-tim salary the effect upon the proficiency of the professio would be impossible to calculate. The Lord Chancellor motion was agreed to.

At a later stage the Royal Assent was given to th Bill by Royal Commission.

THE SCOTTISH HEALTH BILL

THE National Health Services (Scotland) Bill, intro duced on the last day of the session, differs from th English Act as regards hospital endowments, the positio of the teaching hospitals, and the provision of healt centres.

The endowments of each voluntary hospital transferre to the Secretary of State for Scotland will pass, in th he board of management responsible for nd the board will hold them in trust were held before. The Secretary of State wever, to set up a Hospital Endowments review all endowments and make schemes e management. Such schemes may specify purpose for which endowments are to be permit their use for any purpose related or specialist services or to research : and in schemes the commission is to take into spirit of the intention of the founder of the t as well as the interests of the hospital service The commission will consist of a chairman by the Secretary of State and other members d as he may determine.
